# Reader's Guide

---

The Reader's Guide is provided to assist readers in locating articles on related topics. It classifies articles into nine general topical categories: Academic Disciplines; Case Study Research Design; Conceptual Issues; Data Analysis; Data Collection; Methodological Approaches; Theoretical Traditions; Theory Development and Contributions From Case Study Research; and Types of Case Study Research. Entries may be listed under more than one topic.

## **Academic Disciplines**

Case Study Research in Anthropology  
Case Study Research in Business and  
Management  
Case Study Research in Business Ethics  
Case Study Research in Education  
Case Study Research in Feminism  
Case Study Research in Medicine  
Case Study Research in Political Science

# About the Editors

---

**Albert J. Mills**, PhD (professor, management), is Director of the PhD (management) program at Saint Mary's University (Nova Scotia, Canada). Leaving school at 15, his early images of organization—of frustration, power disparities, conflict, and sexually segregated work—were experienced through a series of unskilled jobs and given broader meaning through campaigns for peace, social justice, and human liberation. An early concern with discrimination led him to an interest in the relationship between knowledge (how a sense of self is developed), history (the contexts in which selves are constructed), and human liberation (how we are constrained by contextualized knowledge). He has pursued this focus through active involvement in a series of scholarly organizations, and more than 250 publications, culminating in work on a book (with Gabrielle Durepos) on ANTi-history—a liberationist approach to (past) knowledge.

Mills's feminist work ranges from involvement on university equity committees, leadership roles in the Gender and Diversity in Organizations divisions of the Academy of Management (AoM) and the Administrative Sciences Association of Canada (ASAC), and membership on the editorial boards of *Equal Employment International* and *Gender, Work and Organization* (associate editor). His books on gender and diversity include *Gendering Organizational Analysis* (1992), *Managing the Organizational Melting Pot* (1997), *Gender, Identity, and the Culture of Organizations* (2002), *Identity Politics at Work* (2004), and *Sex, Strategy, and the Stratosphere: The Gendering of Airline Cultures* (2006).

Mills's commitment to social change has led him to involvement in Critical Management Studies

(CMS), as stream organizer at several international CMS conferences, and as chair of the CMS Division of the Academy of Management. He is currently on the editorial boards of *Organization, Tamara (Critical Postmodern Studies)*, the *Canadian Journal of Administrative Sciences* (as CMS editor), and the *Journal of Workplace Rights*. His books in the field include *Organizational Rules* (1991), *Reading Organization Theory* (1995, 1999, 2005), and *Organizational Behaviour in a Global Context* (2007).

Finally, Mills's interest in knowledge has led him to explorations of management education and the role of research strategies, including historiography, case study, and postpositivist research methods. In terms of management education, he has served as an active researcher and executive member of several organizations, including ASAC (as president), the Atlantic Schools of Business, and the International Federation of Scholarly Associations of Management. In terms of research strategies, he is currently on the editorial boards of *Qualitative Research in Management and Organizations* (associate editor) and *Management and Organizational History*, and is completing two books—*Business Research Methods* and *Darkside of Business Case Studies*, which explores the use of teaching with cases. He is also engaged in a series of ongoing case studies and histories of airline companies, and histories of management thought and scholarly associations in North America.

**Gabrielle Durepos** is an assistant professor at St. Francis Xavier University in Nova Scotia, Canada, where she teaches organizational behavior. Growing up in a 20th-century Western society that saw the rise of dominant grand narratives, Durepos has

been continuously fascinated by the process in which knowledge assumes a status of “truth” and the subsequent potential of that knowledge to govern an entire society’s meaning-making activities. The central strand that bounds all of her research interests is “knowledge,” including knowledge production, legitimation, and dispersion. Her research interests are far-ranging and include history (knowledge of the past) and historiography (how one creates knowledge of the past), the sociology of knowledge, epistemology, the philosophy of the natural sciences, the cold war and its influence on management thought and knowledge, organizational ethics (a collective shared knowledge of what are deemed “good” and “bad” behaviors in organizations), and the development of methodologies.

Durepos has recently been engaged in the crafting of an alternative approach to historiography that offers the potential to craft organizational histories, as well as to historicize research and knowledge. Termed ANTi-history, the historiographic approach has been developed through meticulous archival research and offers scholars specific advice on the rigorous use of the archive. Though the present application of ANTi-history is based on archival materials from the Pan American Airways archive at the Otto Richter Library, she and Albert Mills have planned its future application in terms of theorizing the influence of the cold war (as based on archival materials from the Tamiment Library) on management thought in Canada and the United States.

Durepos has published her work in peer-reviewed journals, including *Management & Organizational History* and *Journal of Management History*. She has played an active role in the organization of the Atlantic Schools of Business conference and is an associate editor for the *Canadian Journal of Administrative Sciences*.

**Elden Wiebe**, PhD, is an associate professor of business, department of management and commerce, The King’s University College, Edmonton, Alberta, Canada. He is currently developing and combining three central research interests. Organizational change is one central research focus, an interest that grew from having worked in contexts where significant organizational change

was desperately needed but never undertaken, and where significant organizational change had occurred only to be reversed within a few years, thereby again incurring the same problems that the original change had resolved. Temporal embeddedness is a second research focus, specifically time in the context of organizing, organizations, and organizational change. Observing and personally experiencing the tyranny of the clock in human relations has led him to pursue understandings of time that extend beyond the singular expression of time as a technology symbolized by the clock. His third research focus is spirituality, which stems from his long-standing involvement in Christian spirituality, developed over years of participation in organizations dedicated to addressing justice, human well-being, and the spirit. This has led him to research the growing phenomenon of spirituality in the workplace.

Wiebe’s recent work has combined his interests in organizational change and time. His research investigates individual managerial temporal sensemaking and how it affects managers’ implementation of change and their individual response to the change as they construct it. This work is the focus of his recently completed dissertation. An earlier version of the theory chapter from the dissertation won the Doctoral Student Scholarship at the Future of Time in Management and Organizations conference (INSEAD), sponsored by the International Network for Time in Management and Organization, the Center for Creative Inquiry located in San Francisco, and the Organizational Behavior and Organizational Development and Change divisions of the Academy of Management. Work with colleagues on investigation of organizational change (methodology) has been published in R. Lunes, A. Langley, and I. Stensaker (Eds.), *Handbook of Organizational Change and Learning*. His current work on time/temporality and change examines how the relationship between family physicians and patients is being shaped by the emphasis on efficiency, a phenomenon based in clock time, in the context of increasing wait times within publicly funded healthcare services. Work with colleagues on the regionalization of healthcare services has been published in *Healthcare Quarterly*.

Wiebe's commitment to spirituality has led to combining his interests in spirituality and organizational change. He is currently involved in a Social Sciences and Humanities Research Council-funded grant examining why and how spirituality is incorporated into the workplace, and what effect it has on employees and the workplace.

His initial work with colleagues has been published in the *Journal of Management Inquiry*.

Wiebe is a member of the Academy of Management and the Administrative Sciences Association of Canada. He is also an active supporter of the Center for Spirituality and the Workplace at Saint Mary's University.

# Introduction

---

Case study methodology has a relatively long history within the sciences, social sciences, and humanities. In sociology, for example, there is evidence that the case study approach was being “pioneered” at the University of Chicago by 1920, as sociologists attempted to illuminate the social instance (e.g., the immigrant experience in the United States) through detailing the particular (e.g., the study of selected Polish immigrants) (see Chicago School entry).

Much of this early case study research was incorporated in qualitative research strategies, but the tradition also developed as part of quantitative and mixed methods research strategies. This was true of medical research, for instance, where the case study approach dates back to the early 1930s and was initially viewed as useful for assisting researchers in making valid inferences from events outside the lab in ways yet consistent with the rigorous methodology of laboratory science (see Case Study Research in Medicine entry).

Over time the case study approach garnered interest across various disciplines as researchers sought to illuminate phenomena through detailed study of their occurrence in a particular context. Today case study research can be found across various sciences (see Decision Making Under Uncertainty), the humanities (ANTi-History), and the social sciences (Case Study Research in Political Science), embracing qualitative (Autoethnography) and quantitative (Before-and-After Case Study Design) research strategies, positivist (Causal Case Study: Explanatory Theories) and postpositivist approaches (Actor-Network Theory), and the practice-oriented fields such as education, management, public administration, and the human services (see, respectively, Case Study Research in

Education, Case Study Research in Business and Management, Case Study Research in Public Policy, and Case Study With the Elderly).

Despite this long history and widespread use, case study research has received perhaps the least attention among the various research strategies in the literature on research strategies. In the social sciences, for example, only a few texts deal directly with case study as a central subject, and no encyclopedic reference provides a thorough overview of design and methods in case study research as guidance for students, researchers, and professionals trying to incorporate case studies into a rigorous research project or program. This encyclopedia is intended to be that authoritative resource by combining entries from across the social sciences and humanities, and encouraging work from across the methodological traditions to include feminist, poststructuralist, critical, postcolonial, interpretive, postmodernist, historical materialist, racio-ethnic, as well as positivist entries.

The development of the *Encyclopedia of Case Study Research* was exciting and challenging. It provided an opportunity to expose a large number of researchers to the value of case study research, but it also offered the challenge of making it interesting and understandable to as wide an audience of researchers as possible. Our challenge has been to make case study relevant to researchers at various stages of their careers—from student to seasoned academic; across philosophic divides—from positivism to postpositivism; across disciplines as diverse as music and anthropology; across the international divide; and from qualitative to quantitative researchers, as well as those interested in mixed methods. In the process, we also hoped that the encyclopedia would appeal to the end users of

research. Thus, we drew on a vast number of contacts and networks to encourage contributions from case study scholars from various disciplines and philosophical orientations across the globe. We were aided in our endeavors by an international editorial board consisting of many of the leading researchers in the field. Our hope is that we have succeeded in our overall aim of providing an accessible but far-reaching encyclopedia that will become not only a valuable resource but will encourage new and renewed interest in case study research as well.

The *Encyclopedia of Case Study Research* (two volumes, approximately 1,100 printed pages) provides a comprehensive compendium covering the important methodological issues encountered in doing case study research, and exploring both their strengths and weaknesses from different paradigmatic approaches. The focus is on the distinctive characteristics of case study strategies and their place within and alongside other research strategies. From beginning to end, this work covers the spectrum, addressing such overarching themes and general topic areas as:

- The scientific method
- Comparing the case study with other research methodologies
- The role of theory in case study research
- Types of case studies (e.g., explanatory, exploratory, descriptive)
- Case studies within various disciplinary contexts (psychology, business, etc.)
- Designing case study research
- Principles of data collection with case study designs
- Conducting case studies
- Analyzing case study evidence
- Composing case study reports
- Evaluating the quality of case study research design and findings
- Using case studies as one part of a multimethod research program

In the spirit of different research traditions, we have avoided standardization of certain terms and concepts, which in some cases are capitalized and in others not; and in some places are italicized for emphasis and in others not.

## Defining Case Study Research

Defining case study research is both easy and problematic. It is problematic because the very essence of our approach of bringing together case study researchers from across the paradigmatic divides and across various disciplines means that any definition needs to be all encompassing. As you will find throughout the encyclopedia, definitions of case study vary across disciplines, especially according to the underlying philosophies (or paradigms) involved. On the other hand, there are common threads across all the entries that allowed us to make decisions about what was and was not an applicable entry on case study research. Thus, in the process of developing an all-inclusive work we constructed a particular view of what it is that constitutes case study.

Simply put, case study is a research strategy whose characteristics include

- a focus on the interrelationships that constitute the context of a specific entity (such as an organization, event, phenomenon, or person),
- analysis of the relationship between the contextual factors and the entity being studied, and
- the explicit purpose of using those insights (of the interactions between contextual relationships and the entity in question) to generate theory and/or contribute to extant theory.

Here we propose four noteworthy points concerning our description of the case study: First, and foremost, our definition, like all definitions, serves to limit the object of inquiry but hopefully in a way that is not too restrictive. Second, as such, our definition should be taken as a heuristic, or sense-making device, for *guiding*, rather than dictating, your understanding of case study research. Nonetheless, in keeping with the philosophy of our approach, our definition—like all definitions—should be viewed as a social construction for making sense of the common threads across contributions. Our definition is not meant to be definitive nor authoritative to the exclusion of other equally valid definitions. Third, we have chosen to call case study a research *strategy* rather than a method or methodology. Method implies a research tool, such as surveys, interviews, or observations, and case

study cannot be reduced to a single method. Methodology can refer to the use of a particular method or methods *and* the theoretical framework that informs its use. To take the example of interviewing: Some researchers may use interviews as a method for finding out what people *actually* think about something, while poststructuralist researchers may use interviews to assess how powerful ideas in practice (e.g., employment equity, privatization, fitness) influence the way people think and treat something as knowledge. Case study can involve any combination of methodologies and methods and so is perhaps better described as a strategy to capture the decision making that goes into developing a particular case study. Fourth, we have linked our definition to the focus, form of analysis, and explicit purpose of the research strategy. In other words, a case consists of a focus on the link between a specific entity and its supposed contextual interrelationships, and on what the link can tell us about either the uniqueness of the case or its generalizability to comparable relationships.

#### How to Use the *Encyclopedia of Case Study Research*

The encyclopedia consists of 357 entries arranged in alphabetical order over two volumes. Each entry provides the reader with an overview of a specific topic or issue in case study research. In each entry, readers will first find a definition of the headword followed by a conceptual overview and discussion of key issues pertaining to that headword. Since we were particularly concerned with the *doing* of case study research, readers will typically find an application of the headword, either in terms of a direct description of “how to” or in the form of a description of an example of a case study that embodies the headword. The identification of a specific case study where the headword is applied is especially useful, since it grounds the headword in an actual case study and provides readers with a concrete example, which they can later consult as an additional reference material. Each entry concludes with a critical summary that reflectively raises additional issues of which practitioners of case study research should be aware. Finally, further insight into the headword is then provided

through a list of cross-references to other relevant headwords in the encyclopedia and a list of references for further in-depth investigation.

The encyclopedia contains an entry titled Case Study as a Methodological Approach. Unlike other entries, which deal with specific aspects of case study research, this entry provides an overview of case study research. It does, however, share with all other entries an underlying philosophy that informs its approach and should be read in that vein.

An additional feature of the encyclopedia readers will find helpful is the Reader’s Guide, located in the front matter of each volume. The Reader’s Guide organizes all entries under nine thematic topics for easy reference. For example, readers may wish to turn first to an overview of case study research within their discipline. The Reader’s Guide lists each discipline addressed under the heading of Academic Disciplines. Other categories include Theoretical Traditions, Methodological Approaches, Types of Case Study Research, Case Study Research Design, Data Collection, Data Analysis, Theory Development and Contributions From Case Study Research, and Conceptual Issues. Each entry in the encyclopedia will be listed under at least one of these broad thematic headings.

At the end of the encyclopedia (in Volume 2) we have included a section called “The Fun and Value of Case Study Research.” Here we asked contributors to share their sense of the enjoyment as well as the value of case study research. The result is a selected group of five researchers who share their views of how case study research can be as meaningful and as much fun as it is rigorous and methodical. Our aim here is to provide a different way of “getting inside” the case study researcher’s viewpoint. Linked to these contributions is a section called “Favorite Cases” where contributors share their opinions on the case studies that have influenced their own work and thinking. Here you will find an array of views and further information on the types of case studies that influence case study researchers. Our aim is to provide a different way of exposing readers to the importance of case study research and a guide to further reading.

Finally, we provide a list of case studies selected by many of the contributors and editors of the

encyclopedia. This allows readers to follow up on selected themes, to explore the work of contributors, and to gain a sense of the depth of expertise involved in the two-volume work, and provides another resource for further reading.

### Acknowledgments

An encyclopedia encompassing such breadth and depth—breadth of disciplines, philosophical paradigms, and geographic situatedness of case studies, and depth of experience, knowledge, and insight into case study research—could not have been produced without the gracious and careful efforts of practitioners of case study research worldwide. We as an editorial team have been humbled by their commitment to the case study strategy, by their insight into doing case study research, and by their commitment to the people and issues that formed the focus of their own respective case studies. To all who contributed to the encyclopedia, we are especially grateful.

We are also particularly thankful for the outstanding (and this word is understated) contribution of our managing editor, Marion Weatherbee. Marion has brought exceptional organizational

skills to this endeavor, freeing and focusing us as editors to do the work of editing.

We have also been blessed to work with a superb team at SAGE. James Brace-Thompson, who first proposed the encyclopedia to us, has been a constant source of support, encouragement, enthusiasm, and energy. Carole Maurer, our developmental editor, has worked closely with us to gauge our progress, helping us to find ways to continue to move forward in a timely fashion and assisting us with myriad questions and issues over the course of developing the encyclopedia. Our expressed thanks do not adequately convey our depth of appreciation for you. Finally, Laura Notton and Leticia Gutierrez have provided invaluable support through the Sage Reference Tracking System, which has made a logistical monster into a benign house cat.

In conclusion, we are grateful for our readers, both novice and seasoned researchers, who wish to learn about or further develop their abilities in case study research. It is because of you that this has been a labor of love.

## ABDUCTION

---

Abduction is the process of forming a possible explanation involving an imaginative effort to understand on the part of beings acting and learning in a world. It is a practical reasoning mode whose purpose is to invent and propose ideas and explanations that account for surprises and unmet expectations. Within the context of scientific endeavors, abduction is the basis for the inventive construction of new ideas, explanatory propositions, and theoretical elements. Its importance lies in highlighting the discovery dimension of research, especially the central role played by puzzles, hunches, speculation, imagination, guesswork, and the like, in the process of developing theoretical insights. This entry provides an overview of the process and its application.

### Conceptual Overview and Discussion

In the late 1800s the founder of pragmatism and polymath, Charles Sanders Peirce, distinguished abduction as a third form of inference necessary for a more complete understanding of the processes of intelligent inquiry. Deduction, as the form of necessary reasoning from which we derive specific observations from generalizations, has dominated Western scientific thinking for over 2,000 years. Not quite as long lived, induction, as the form of probabilistic reasoning from which we derive generalizations from specific observations, has been a feature of modern science for some 700 years.

About a century ago, Peirce suggested that there is a broad class of reasoning that is neither deductive nor inductive but involves inferences from effects to causes. He pointed out that both deduction and induction are closed with reference to the concepts in play. Another form of reasoning was needed to generate new concepts; he came to call this form of reasoning *abduction*. Not to be confused with *inference to the best explanation*, which begins from already established hypotheses, abduction is the mode of inference aimed at developing new ideas. Its basic formula is

The surprising fact, C is observed:

But if A were true, C would be a matter of course,

Hence, there is reason to suspect that A is true

As the presented formula for abduction indicates, it is an inherently transactional process and the element of surprise plays a critical role in stimulating it. The surprise may be relatively active, as when one makes an effort to anticipate a particular result that does not occur, or it may be passive, as when a situation presses itself on one's consciousness. When expectations fall short in some way, abduction is triggered. A central tenet of Peirce's epistemology is that all thinking behaviors, from perception to logical and mathematical reasoning, are mediated by signs. Consequently an observation's status as "fact" or as "surprising," and as the impetus to abduction, is never given purely; it is always mediated by modes of perception, by background perspectives and theories. Its

surprising character exists only with respect to certain expectations held under certain circumstances. Surprise signals a need and an opportunity to invent a new way of understanding.

Stimulated by surprise, abduction is involved when scientists struggle for new kinds of intelligible patterns in observations—that is, when they strive to generate a possible “A.” The struggle may involve many possible imaginative elements, including hunches, guesses, conjectures, associations, metaphors, speculations, propositions, models, and so on. Furthermore, abduction need not occur in the context of existing language because the formation of new explanations often goes hand in hand with the development of new or newly combined theoretical terms such as “quark,” “AIDS,” and “garbage can model of decision making.” As a form of reasoning, it is suppositional, suggesting only what “may be.” However, abduction’s value and weakness are two sides of the same coin. It is weak in the sense that the “might be’s” entertained are highly permissive; yet that very permissiveness is the source of inventiveness. What at first blush may seem irrelevant, just a loose notion or even nonsensical, may be the beginning of novel ways of understanding.

For some time, the notions of abduction and discovery were controversial issues in the philosophy of science following the claim that the invention of new ideas, concepts, or theories are chance occurrences and, therefore, inappropriate to epistemological considerations. Karl Popper, for example, was one of the most outspoken critics of the idea of a reasoning process for creating novel possibilities. Increasingly, however, philosophers of science and researchers recognize that emphasis has been placed on validation, and they are now to a greater extent attending to discovery processes as part of the work of doing science.

### Application

Abduction is not a new approach to analysis and interpretation. Ironically, the process of abduction has likely been a critical part of most interesting theorizing from case research. Perhaps due to the long-standing bias against discovery within the philosophy of science, or due to the apparent inconsistency between the received view of scientific method

and the character of the abductive process, or because case researchers have traditionally subsumed abductive work under the category of induction, it has remained hidden. Accounts of the theorizing process in methodology texts and also in the methods sections of published journal articles generally present theorizing as a validation exercise in which conjectural and imaginative processes play no role.

Clarifying abduction has several implications for how we think about theorizing. First, it calls attention to the imaginative dimension of theorizing, in legitimizing the role played by permissive exploration grounded in the particulars of detailed observations to the development of theoretical insights. It underscores that hunches, guesses, speculations, and loose notions are all essential elements in the theorizing process, and it attests to the value of being deliberately expansive and playful in thinking with observations.

Second, from the perspective of abduction, observations or data are a resource for possible puzzles and speculation. Detailed observations generated through the research process are treated as potential indicators of some processes, structures, or characterizations. Third, it highlights the importance of all departures from expectation to generating insights, for example, surprises, puzzles, and glitches. Indeed, it suggests that researchers should actively court situations that somehow do not square with their expectations and preconceived notions because, in Howard Becker’s terms, not knowing what one has a case of is highly productive for one’s research efforts. Fourth, clarifying abduction highlights that the lived experience of theorizing is messy, half-blind, wasteful, difficult to articulate, and lengthy. Observations are made, hunches occur, ideas are developed and are tried out in relation to existing or new observations, they are modified or set aside, new ideas are developed, and so on. If abduction is permissive, then false conjectures and blind alleys are necessarily part of the process. Abduction is fallible.

Finally, as a permissive and fallible process, abduction must occur in recursive interplay with deduction and induction in order to arrive at plausible theoretical insights. Ideas have to be articulated and worked out in relation to one’s generated data and what one already knows.

### Critical Summary

Deduction and induction provide an inadequate conceptual vocabulary to account for the process through which new theoretical insights are generated. Specifically, the concept of abduction is needed to highlight the everyday imaginative work central to interesting theorizing.

## ACTION-BASED DATA COLLECTION

---

Action-based data focus on what research participants do in their day-to-day activities. Who does what, when, where, and how captures the essence of this focus. Questions of why may also be addressed. Any form of data may be collected, including interviews, observations, and documents

that show evidence of action that occurs in the case. The role of the researcher may be anywhere along a continuum from detached observer to participant observer to full participant, with the research taking various forms from ethnographic case study to a case of action research in which, by researching their own practice, researchers are full participants. This entry provides an overview of the process and its application.

### Conceptual Overview and Discussion

Action-based data collection takes place in the natural context of the case and is usually a cyclical process occurring over time. Two collection systems are discussed here that work nicely together: James Spradley's descriptive question matrix helps illuminate what to focus on as action-based data; Herbert Altrichter, Peter Posch, and Bridget Somekh give several suggestions for ways to collect these data.

Spradley, along with others, suggests beginning with “grand tour” observations that give the researcher an initial sense of the parameters of the case that can provide pointers for what to focus on in the next cycle. Spradley suggests nine dimensions of any social situation that provide a comprehensive map for action-based data collection:

1. *Space*: the physical place or places
2. *Actor*: the people involved
3. *Activity*: a set of related acts people do
4. *Object*: the physical things that are present
5. *Act*: single actions that people do
6. *Event*: a set of related activities that people carry out
7. *Time*: the sequencing that takes place over time
8. *Goal*: the things people are trying to accomplish
9. *Feeling*: the emotions felt and expressed (p. 78, italics in original)

Spradley uses these dimensions to create a 9 × 9 Descriptive Question Matrix, which then leads to 81 specific questions, including the following:

*Activity × Activity*: Can you describe in detail all the activities?

*Activity × Goal:* What activities are goal seeking or linked to goals?

*Act × Space:* What are all the ways space is organized by acts?

*Event × Time:* How do events fall into time periods?

*Time × Event:* How do events occur over time? Is there any sequencing?

*Objects × Acts:* What are all the ways objects are used in activities?

There are several advantages to using a matrix like this. It helps broaden the researcher's attention to several social dimensions that might be ignored and helps focus attention on specific action-related details. The grand tour can also point the way to areas that may provide more fruitful detail for the case under study. As can be seen from the detail described, carrying out action-based data collection can be time intensive if the researcher hopes to capture the range of actions over time. The time frame may be bounded by the case study focus.

Altrichter, Posch, and Somekh suggest several ways to collect data for action research that work well in any action-based data collection process, pointing out that the research question will determine what may become data. Existing data provide evidence of past events and include such things as documents and physical traces such as wear and tear on furniture and objects, materials available to everyone or only certain people, signage, sales slips, and so on. These data have high credibility because they were created as part of the day-to-day business of case participants rather than only for research purposes. However, it is important to collect only what is relevant to the present research.

Another category of action-based data collection is the systematic observations and documentation of situations. Because situations are dynamic and action filled, it is important for researchers to choose a clear focus before the observation period starts by deciding what they will observe, why they are observing this particular phenomenon, and when and for how long this particular observation will take place. Because actions happen quickly, it is useful to prepare an observation protocol format.

For example, when wanting to observe the hand-raising/discussion pattern in a classroom, making a diagram of the desks, then using symbols

such as F for female and M for male, indicating a backslash (/) on the desk when a comment is made and a question mark (?) when a question is asked, a check mark when a correct answer is given, and an "x" when one is not. This provides a clear, focused, efficient way to collect action-based data. This protocol can be filled in during the observation and then fleshed out more fully after the actual observation with comments on kinds of questions and comments, gender balance, suggestions for further systematic observations, and anything else pertinent to the research.

Protocols can be created for any kind of observation. Using other people as observers can give fresh perspectives. Photographs, videos, and audiotapes also provide ways to collect action-based data, as does observation of trace materials. For example, participants' self-reports of alcohol consumption to the researcher might not match what is found in their garbage or recycle bins. Observing wear on things such as steps and elevator buttons is an unobtrusive way to document indications of human activity. Finally, interviewing participants in the case can help elucidate underlying meanings of the actions as well as provide new data sources to explore.

### Application

Altrichter, Posch, and Somekh point out that what is produced or selected is influenced by the researcher's point of view and that data are static because of their material nature (e.g., a photograph), thus removing the dynamic reality of actions and events. They also point out that the data collected are not reality itself, but only traces left behind. Perhaps the most important thing Altrichter, Posch, and Somekh describe is their Ladder of Inference. They describe three steps:

1. Relatively unambiguous observational data (e.g., "The teacher said to the pupil, 'John, your work is poor.'")
2. Culturally shared meaning (e.g., The teacher criticizes John)
3. Meaning of a sentence for a specific listener (e.g., The teacher is not empathizing with John)

Data collection needs to be as close as possible to what is seen and heard with inferences and interpretations left for a later step. Three nonleading

action-based questions that can open initial discussion with participants in a case are: What are you doing? Why are you doing that? How is it going? Documents and physical trace evidence can also be used to start initial interviews with participants. Participants can also provide information that could lead researchers to documents and other things of which the researcher may have been unaware. To increase validity, action-based data need to be collected at different times as well as from different participants and perhaps different places, depending on the focus of the case.

Dennis Greenwood and Del Lowenthal differentiate between positivistic and hermeneutic points of view, each of them capable of leading to very different purposes and foci for collecting action-based data. For example, an action research case study takes on a different analytic dimension from an ethnographic case. If the purpose of an ethnographic case study is to understand the phenomenon as it occurs, the purpose of an action research case study is to examine one's own practice in order to improve it.

### Critical Summary

Action-based data collection can provide authentic on-the-spot data that are richly descriptive of the case. Action-based data collection can help uncover dynamic complexity and show various nuances of the case that increase understanding of the phenomena. However, researchers need to ensure they have collected enough data over a long enough time period to create a valid and reliable case. Researchers can never collect "all" the data, so they need to be aware of and share the perspectives they were using at the time of data collection. Researchers also need to pay special attention to Altrichter, Posch, and Somekh's Ladder of Inference, being cautious about moving too quickly from description to interpretation.

## ACTIVITY THEORY

---

Activity theory is a framework for understanding collective processes undertaken in pursuit of some higher goal. It has its roots in the writing of Karl Marx and Lev Vygotsky and was conceived, as activity theory, by Alexei Leont'ev. From this theoretical perspective, the key unit of analysis is the activity, generally a sustained societal activity such as farming, schooling, environmentalism, or banking rather than a short-term event such as a classroom lesson or one-off interaction between people. Activity systems (communities engaged in activities) are understood through attention to their: subject (the individual or group engaged in activity), object (the goal of the activity with its attendant motivations), actions (processes undertaken to reach the objective), and operations (the underlying and often unconscious microprocesses that make up actions).

### Conceptual Overview and Discussion

Activity theory has been described as one of the best-kept academic secrets. Despite its origins in the early 20th century, Wolff-Michael Roth, in a search of *Social Sciences Citation Index*, found that the majority of literature published in the Americas and Europe on the concept has been published in the past two decades. Its use has increased dramatically since the early 1990s in many areas of social science, including anthropology, education, psychology, and human-computer interaction.

The concept at the core of activity theory is that the individual-in-context does not merely react to his or her surroundings but has the power to act to change his or her actions and therefore change the community and the surroundings. Conversely, participation in a community is commensurate with change in one's participation and therefore constitutes learning. From this perspective, learning is

conceived as mutual change of subject and object through engagement in activity.

Consistent with this core principle, all aspects of an activity system are understood to exist in dialectic—the mutual exchange between theoretically opposite components such as subject and object. Therefore, though we identify constituent parts, none can be understood without attending to the others.

One of the key frameworks for understanding activity requires attention to subject, object, action, and operation. *Subject* refers to an individual or a group with a defined and shared goal. It is important to clarify that when a group or community is understood as the subject, the goal must be shared and continue to be shared. Individuals are not a community simply by being located together in time or space. *Object*, taken in the same sense as the noun *objective*, refers to the understanding, held by the subject, of the purpose of the activity. It provides the motivation and direction for the activity. For example, a group of teachers and administrators at a school may be thought to engage in the activity of schooling. The group is the subject and the motivations and goals that they share constitute the object. The object in this activity system may be different from that of another group of teachers also engaged in the activity of schooling because it is defined by the shared objectives of the particular community. On the other hand, one may consider all teachers and administrators in a society as a community (the subject) with a different set of shared objectives (the object) engaged in the activity of schooling. Understanding through activity requires careful definition of these terms and of the activity, subject, and object under consideration.

Once the subject and object are defined, attention can be turned to the *actions*—the processes undertaken by the individuals or community members toward the achievement of the object. They are considered conscious and chosen with the object in mind. For an individual, there are many different actions that may be undertaken to achieve the same object. Similarly, individuals in a community may undertake different actions, depending on their strengths and abilities, in pursuit of the object. Through different actions they each contribute to the achievement of the object.

The final aspect is that of *operations*—the unconscious microscale procedures that make up

conscious actions. These are aspects of carrying out actions that have been practiced and completed so often that they are routinized and not attended to explicitly. For example, the action of letter writing as part of the activity of activism does not require the subject to attend to the micro-processes of how to turn on the computer, how to access word processing software, or how to use the keys to type. These are the operations that constitute the action of letter writing.

It is important to note that aspects of the system can change their meaning. For example, actions can become operations as they are practiced and eventually routinized. Bonnie Nardi proposes the analogy of gear shifting. For those familiar with gear shifting in a car, at first it is a conscious action undertaken to accomplish the object of operating the car, but in time it becomes an unconscious operation conducted to arrive at a destination. Similarly, operations can become actions if they are impeded in some way and the subject must return conscious attention to them. For example, a change from driving a small car to a large commercial vehicle may force the subject to once again attend consciously to the use of the clutch and gear shifting patterns.

In addition, objects can be transformed in the process of an activity as subjects change and learn. For example, teachers working together to address a new student population (as part of the activity of schooling) may begin with particular goals, but as they learn about the students they may extend and shift their focus, thereby changing their object.

None of these relations (between subject, object, actions, and operations) are strictly linear or fixed. They exist in dialectic. They are, however, stable beyond the moment. Changes that occur are not trivial; changes in object can effect fundamental change in the activity. For example, large-scale changes in teachers' objects can fundamentally change the activity of schooling.

To understand these relationships, Yrjö Engeström proposed a model in the form of embedded triangles. The model focuses on the ways in which subject and object are related to each other and the ways in which their relationship is mediated by artifacts (e.g., tools, language, symbols), rules, the community, and the division of labor. This heuristic is an effective way of understanding and analyzing the dialectics that form an

activity system. It also connects modern interpretations of activity systems to the philosophical foundations of activity theory.

The founders of activity theory are generally agreed to be Lev S. Vygotsky, Alexei N. Leont'ev, and Alexander R. Luria, psychologists working in the 1920s and 1930s to understand the connection between individual and surroundings. Vygotsky, in particular, was critical of educational psychologists treating learning processes in the isolation of an individual's brain. For Vygotsky, the unit of analysis was action by a subject in pursuit of an object as mediated by tools and symbols (including language).

Leont'ev, Vygotsky's student, added to this a careful reading of Karl Marx's posthumously published *Theses on Feuerbach*. In it, Marx argued that neither pure materialism nor pure idealism is sufficient to explain change. Materialism cannot attend to human agency, and idealism locates everything in the minds of individuals. The distinction between collective activity and individual action was an important one for Leont'ev. His work addressed the important impact of mediation by people and social relationships, not only by artifacts. Leont'ev made the primary unit of analysis the evolving activity, including an expanded understanding of the mediated relationships between subject and object.

With this connection to Vygotsky, it is important to distinguish between activity theory and other ways of approaching individuals-in-context who have shared history, including situated action and distributed cognition. In arguing for activity theory as an appropriate framework for studying context in the field of human-computer interactions, Nardi focuses on the differences in the unit of analysis for each of these three approaches. In particular, she focuses on the way in which the object is understood. In activity theory, the object is constructed and held by the subject. It is the dialectic relationship between the two that forms the basis of the theory. Distributed cognition takes the system goal to be abstract and not held within the consciousness of the individual. Like activity theory's object, however, the system goal is still considered as the key organizing aspect of the system. Situated action, in contrast, takes goals as retrospective constructions—descriptions of our motives created after the fact. Situated action takes the perspective that activity and its values are co-constructed in

the moment—we are thrown into ongoing activities that direct our actions more than we engage in intentionality located actions. Activity theory, on the other hand, ascribes agency to the subjects to construct objects and undertake (socially mediated) actions to achieve them.

### Application

In attempting to study or apply activity theory there is often a tension regarding whether it should be approached primarily as an explanatory concept to address why activities are the way they are or as a methodology, a way of approaching the study of activities. It is used in both ways, often by the same authors, and defined in a general sense that allows for both conceptualizations. For example, Roth defines it as a resource for theorizing, a road-map, and a metatheory for understanding complex situations. Engeström's triangle is often used as a heuristic for analysis, to aid in the identification of the components of the activity system.

In all of these approaches, however, it is primarily a case study method that is used to understand subject-object activity relationships. The focus on the individual-in-context means that case studies are one of the most appropriate ways of examining individuals and activity systems.

One common approach is the activity-level case study. For example, in 2002 Kirsten Foot used a single case study of a community (the Network for Ethnological Monitoring and Early Warning, a network of post-Soviet conflict monitors) to explore object construction. She focused on the way the community object was constructed in the discourse of the participants. She highlighted that, contrary to her initial impressions of scattered individual objectives, the network was a functioning activity system organized around a single, though complex, object.

Another approach is that of the individual-level case study. For example, Anna Pauliina Rainio, in her 2008 study of agency in schools, presents the case of Anton, a 7-year-old boy, as he is engaged in joint narrative construction with his class and teacher. She profiles how he tests and expands his classroom agency through his participation and traces his trajectory from resistance to engagement. This case study hits at the heart of activity theory—change in activity through individual participation

and change in the individual through participation in the activity. Anton's trajectory is understood through this lens.

Finally, researchers may also use multiple case studies to explore the ways in which different communities engage in the same activity. In other words, they focus on different activity systems oriented to the same activity. For example, Andreas Lund, in a 2008 study of assessment practices, explores two different communities (student teachers assessing exam papers in an online environment, and secondary school students conducting peer assessments) engaged in the activity of assessment. Because they are different communities they include different subjects, potentially with different objects and both similar and different mediating tools, rules, and community relationships. Lund uses the cases to establish these communities as activity systems and assessment as a mediated collective practice. The communities, despite their differences, are therefore engaged in a common socially mediated activity: assessment.

These are typical of activity theory analyses with general goals of understanding communities as activity systems, exploring the constituents of activity (e.g., subjects, object, actions, operations), and understanding changes at both the subject and the activity level.

### Critical Summary

Activity theory is a framework for understanding and analyzing collective goal-oriented processes. It focuses on the mediated relationships between subjects (individuals and communities) and objects within the context of societal activities. Harry Daniels, however, has asserted that for it to reach its potential as a framework, researchers must pay greater attention to further development of the theory, in particular to conceptualizing the ways in which the structural aspects (e.g., rules and symbols) are produced. Others, such as Hamsa Venkat and Jill Adler, criticize it for not having the capacity to attend sufficiently to the experiences of individuals, especially the differences between individuals participating in the same activity. Despite these concerns, it is a strong theoretic framework that attends to mediation not only through language and tools but through rules, social interactions, and relationships. The general unit of

analysis, the activity system and its parts existing in dialectic, provides a complex frame for understanding human actions.

## ACTOR-NETWORK THEORY

---

Originating in studies of science, technology, and society (STS), actor-network theory (ANT)—or the

sociology of translation, according to Michel Callon and Bruno Latour—is an increasingly popular sociological method used within a range of social science fields. ANT gains much of its notoriety through advocating a sociophilosophical approach in which human and material factors are brought together in the same analytical view. In attempting to comprehend complex situations, ANT rejects any sundering of human and nonhuman, social, and technical elements. In a much-cited article, Callon warns, for example, of the dangers of changing register when we move from concerns with the social to those of the technical. The methodological philosophy is that all ingredients of socio-technical analysis be explained by common practices.

### Conceptual Overview and Discussion

A key ANT notion is that of the heterogeneous network, John Law has described this as a manner of indicating that entities (e.g., society, organizations, machines) are effects generated in networks of different materials (e.g., humans and nonhumans). Also, Law suggests that while entities in their broadest sense are usually conceived of as having stability and uniqueness, ANT, in contrast, advocates that they are essentially a result achieved when different heterogeneous elements are assembled together. As such, the ANT approach, for Law, suggests that things take form and acquire attributes as a consequence of their relations with others. As ANT regards entities as produced in relations, and applies this ruthlessly to materials, it can be thus understood, according to Law, as a semiotics of materiality.

As for ANT, entities always exist in networks of relations, this approach suggests that it is not possible to conceive of actors as in some way separable from networks, and vice versa. Following Callon, actor-networks oscillate between that of an actor and that of a network as they engage in sociopolitics, enroll heterogeneous actants, and thus continuously transform and redefine their constitution. This is so because the *activity* of actors and networks is interdependent. For example, for Law, all attributes usually ascribed as human (thinking, loving, acting, etc.) are generated in networks comprising materially heterogeneous networks that either pass through or have ramifications beyond the body.

In this way, a central feature of ANT is to explain how ordering effects—such as devices, organizations, agents, and even knowledge—are generated. Its major focus, at least in its original formulation, is to investigate how entities are performed and kept stable. As a consequence, ANT analyzes the strategies through which entities are generated and held together. For Barbara Czarniawska and Tor Hernes, it tries to unravel the forces that keep actors as one, showing in the process how they are networks that need to be reproduced moment by moment.

Motivated by such concerns, for Latour and Law, ANT implies that organizations and their components are effects generated in multiple interactions, rather than existing merely in the order of things. Organization is perceived as continuous and unfinished, precarious, and partial—a permanent process that generates more or less stable effects; a heterogeneous emergent phenomenon; a verb. According to John Law and Bob Cooper, analyzing organization(s) in this form—stressing that the noun *organization* can exist only as a continuous result of organizing—challenges what mainstream organization studies (OS) approaches usually accept as given or taken for granted. Thus, as suggested by Brian Bloomfield and Theo Vurdubakis, analyzing organizing via ANT is to attempt to address by which means a diffuse and complex system composed of humans and nonhumans becomes networked (for this approach, organizations are outcomes and products of continuing process—relations and practices that are materially complex and whose ordering can be addressed, locally and empirically, only as in-the-making).

To analyze ordering in the making, ANT has deployed concepts such as immutable mobiles and action at a distance. Immutable mobiles have the capacity to fix knowledge and allow it to be disseminated far beyond its point of origin. They represent, for instance, lengthy processes of translating information (e.g., on location in an ocean, a territory's size and shape, virus behavior) into objects that can be carried while retaining shape (e.g., maps, spatial coordinates, sketches, graphics).

By extension, the possibility of acting at a distance implies control at a distance and relies on the alignment of documents, devices, maps, and so forth. In so doing, it relies on establishing a materially heterogeneous network, one that permits

movement and immutability, simultaneously allowing something previously unknown to become acted upon and controlled. Both of these notions—immutable mobiles and acting at a distance—were central to well-known early ANT case studies, such as the history of Portuguese maritime expansion and contemporary scientists at work. These were case studies that subsequently influenced a number of early ANT studies on organization, accounting, and information—studies that suggest issues of organization and control have long been at the heart of ANT.

A further key concept deployed in ANT-inspired analysis is translation, which is for Callon and Latour the work through which actors modify and displace their multiple and contradictory interests. For Callon, translation is the mechanism by which things take form through displacements and transformations; for example, when actors' identities, the possibilities of their interaction, and the limits of their maneuver are negotiated and delimited. Put basically, as suggested by Law, translation processes see entities that are, traditionally, categorically differentiated transformed into ones that are in some ways analytically equivalent, this representing one of the main epistemological tools used to analyze the establishment of actor-networks.

Callon offers a description of this process. For him, translation is composed of four different moments—namely, problematization (or the inter-definition of actors), interessement (or how allies are locked into place), enrollment (or how to define and coordinate roles), and the mobilization of allies (or who speaks in the name of whom? and who represents whom?). Drawing implicitly or explicitly on this way of portraying translation, a number of case studies on organizational issues have been conducted (together with a series of kindred studies on information systems and information technology).

A detailed description of translation in Callon's terms, however, can sound rather prescriptive for a reflexive processual approach such as ANT. More characteristic perhaps is Latour's view that ANT reflects a philosophy that: aims to analyze ordering as complex outcomes of multiple materials, has a strong relational focus that suggests a kind of material semiotics, and declares that a specific ordering process is but one possibility among many. Proposing general rules or aspects of how

translation takes place can be seen as imposing a particular view of how actors get assembled into networks, this being particularly problematic when such a model is replicated incessantly in case studies. Such method therefore seems alien to one of the key ANT mandates: the need to follow actors without imposing preconceived templates or definitions on them. In this context, ANT-inspired analysis has been accused of providing a simplistic view of ordering, one that may influence the potential of this approach being considered critical for management and organization studies.

ANT studies have also been criticized for offering what seems to be a simplistic way of portraying ordering processes. This critique can be clearly linked to translation notions, which appear to provide evidence for a framework that can portray many different cases without any adjustment, that is, in terms that appear to explain almost everything from vaccines to failed aircraft projects. As ANT seems incapable of considering how sociological translations can *differ*, it thus fails to address any variation among processes of ordering, according to Olga Amsterdamska. Even one of the main proponents of ANT notes that studies based on the translation notion can, on the one hand, fail to address how the links that constitute translation are made, while on the other assume similarity among different links, thus limiting ANT's capacity to grasp complexity. Similarly for Steve Brown, whereas recent sociological uses of translation tend to stem from the work of Michel Serres, under ANT the notion suggests a representational aspect that fails to account for the figural and nondiscursive dimension present in Serres's philosophy.

As scholars adopting an ANT position have drawn heavily on the notion of translation to theorize aspects of organizing, such studies may, therefore, have been underscored by the idea that organizing processes in a variety of empirical settings can be accounted for by simply following Callon's four-moments recipe. As a result, instead of being thoroughly and richly explained, a variety of specific organizing processes are described in a nice and tidy way, thus oversimplifying what needs to be explained. Not surprisingly, some have suggested that ANT has often been used as methodological description—as a way to describe and label different actors in a given context. As a consequence, for them, it is possible to question to

what extent ANT ontology has been understood and taken seriously by scholars in OS. By arguing that actor-networks become irreversible once translation is accomplished, ANT is accused of producing a deterministic approach to networks. Vicky Singleton argues similarly that the relative stability of networks depends not on their coherence, but on their *incoherence* and ambivalence, issues that have been generally neglected in early ANT accounts. Susan Star and James Griesemer argue, further, that as translation is frequently told from the point of view of one passage point, and this point is usually the manager, the entrepreneur, or the scientist, this model can lead to a managerial bias, which seems to put ANT in opposition to perspectives that are nonmanagerial and nonperformative (as critical management studies (CMS) claims to be).

However, it is not only the translation notion that can lead to simplistic views of ordering. In some ANT case accounts, ordering may appear as a basic matter of having an effective chain that is able to transport immutable mobiles and action at a distance without detailing the difficulties and problems associated with the dynamics of exerting control. Immutable mobiles, once created, seem to remain the same—because centers and peripheries tend to be portrayed as established locations. This again, however, neglects the potential for resistance and change in relations of power and politics.

Another notion that is seen as leading to a simplistic view of accounting for ordering is the network. Although Law and Singleton suggest it was initially successful in challenging Euclidian spatiality as the network notion has been deployed in a very rigid way, others suggest it later failed to account for all work involved in keeping networks in place. Latour, similarly, argues that the network notion has lost its critical meaning of 20 years ago, when, for ANT, networks were meant to refer to a series of transformations, dependent on the connections and actions that flowed from one actor to another. The idea was to stress movement and change, which, in the main, does not appear to have happened.

The implication is that key ANT notions lead to a singular representation of ordering at the same time that complexities and differences are disregarded. As such, it is argued by Andrea Whittle and André Spicer that this is problematic for the

development of critical perspectives that seek to explore all the complexities associated with relations that establish order, especially those related to power. As Daniel Neyland highlights, some of the ANT applications have forged the kind of fixed location and known theoretical moves that ANT previously sought to avoid. In effect, not only does ANT proffer several problematic notions, but its applications also tend to be acritical. For Jan Harris, Latour's theory has often been reduced to ready acronyms and has been followed by unproblematic application of terms to a given field of study. Consequently, ANT has been accused of providing an analysis of organization(s) that naturalizes organizations themselves.

This simplistic view of organizing also has consequences in terms of how otherness has been addressed in ANT works. Nick Lee and Steve Brown suggest that ANT became a meta-linguistic formulation into which any sequence of humans and nonhumans could be encoded. As such, it became, for Lee and Brown, a final vocabulary that covered everything and risked producing ahistorical grand narratives and the concomitant right to speak for all. As a totalizing system, ANT leaves no space for otherness or noncategories, according to Steve Hinchliffe. It also fails to account for difference, leading to a problematic view of politics, with clear consequences in terms of whether ANT can provide a critical analysis of management and organizations.

Finally, ANT has been charged with avoiding a political stance altogether. Olga Amsterdamska, for example, suggests that ANT analyzes the strengths of alliances that make networks, but rarely the character of them. This sees ANT concerned with questions of how networks are established in terms of relations, but not with whether these relations are characterized by ethical or unethical means. Donna Haraway argues similarly that as ANT rarely asks for whom the hybrids it analyzes work, it neglects the role played by inequality in the production of sociological accounts. As such, ANT's seemingly balanced and symmetrical sociotechnical explanations tend to overlook, or even avoid, questions of politics. Further, Robert Ausch suggests that ANT fails to address how political categories, such as gender, race, class, and colonialism, are established; that is, categories that are not static and a priori, but

that operate as historical modes of conditions that impact and affect relations. According to Susan Star, even though ANT describes heterogeneous engineering, it fails to acknowledge that heterogeneity tends to be different for those who are privileged and those who are not. She points out that accounts in this tradition have a propensity to ignore the problem of hierarchies of distribution. For Michel Reed, similarly, ANT ignores how opportunities are unequally distributed in society. And Whittle and Spicer argue that ANT tends to assume rather than problematize what motivates action and which purposes it serves; it also appears to reproduce, instead of challenge, the networks it describes. In so doing, ANT has been accused of being politically neutral, with critics suggesting it is not an appropriate approach to develop a critical case analysis of organizations.

### Application

An interesting application of ANT has been written by Anamarie Mol. In her book *The Body Multiple*, which draws on field work in a Dutch university hospital, Mol analyzes the day-to-day practices of diagnosis and treatment of atherosclerosis, arguing that within such practices the disease is enacted into existence. It is a well-written application of ANT's latest developments.

### Critical Summary

ANT is a sociophilosophical approach in which human and material factors are brought together in the same analytical view. It tries to understand how entities are enacted into being in a multifarious and complex way.

## AGENCY

---

Agency is the condition of activity rather than passivity. It refers to the experience of acting, doing things, making things happen, exerting power, being a subject of events, or controlling things. This is one aspect of human experience. The other aspect of human experience is to be acted upon, to be the object of events, to have things happen to oneself or in oneself, to be constrained and controlled: to lack agency. As people are both actors and acted upon, the interplay between agency and context is a central issue in case study research across all the disciplines. This entry provides an overview of the concept and its application.

### Conceptual Overview and Discussion

There are three main types of agency: (1) *Individual agency*: The most fundamental form of agency consists of individuals acting, whether at the micro scale (in private or in locales of co-presence) or at the macro scale (in extensive public activities). (2) *Proxy agency*: One agent acting on behalf of

another is known as a proxy. Common examples of proxy agents are employees acting on behalf of employers, managers acting on behalf of the owners of a firm, or officials acting on behalf of a government. A situation in which a principal hires a proxy agent gives rise to what is called the principal–agent problem—a major subject for legal, political, and economic theory. Although nominally acting for the principal, proxy agents can act on their own behalf owing to the divergence of interests and the asymmetry of information between principal and agent. (3) *Collective agency*: When individuals collaborate they create collective entities; insofar as such entities engage in effectual activity, they become collective agencies. Among the numerous examples of collective agencies are firms, states, classes, and social movements. The looser a collectivity, the harder it is to attribute agency to it: A degree of coherence is needed in order to form intentions, make decisions, and act.

There are three main bases of human agency—that is, three key properties of human beings that give rise to agency: (1) *Intentionality*: Human beings are purposive or intentional. This is one source of their agency. Action comes in two varieties: On the one hand, action can be aimless, accidental, or unconscious; on the other hand, action can be purposive and goal oriented. In the latter, people seek out the good things they want in life. Only the latter sort of action involves agency. Lack of agency or the absence of agency is to be found when a person acts unintentionally. Accidental or unconscious conduct involves things that happen to us, rather than things that are done by us. Yet, intentionality is not sufficient to give rise to agency. Goals are not deeds. (2) *Power*: Human beings wield resources and capabilities. This is a second source of their agency. Since power is typically distributed in an uneven fashion, it follows that so too is agency. Some have greater agency than others. (3) *Rationality*: Human beings are rational. They use their intelligence to guide their actions. They calculate how to achieve their ends, and they think about what ends to pursue. This ability to augment action through reasoning accounts in part for the active rather than passive quality of human behavior. To act with effect, it is necessary for agents to reflect upon their circumstances and to monitor the ongoing consequences of their actions. Although not all people at all times have been highly purposive,

powerful, or rational, enough have to impart agency into history and social life.

### *Early Thinking*

Different systems of thought in history have produced varying ideas of the nature and significance agency.

Ancient Greek philosophy developed a distinction between what were later known in Latin as the *vita activa* and the *vita contemplativa*. The former was the active way of life of the citizen with his twin duties of engaging in politics and fighting in war. The latter was the contemplative lifestyle of the philosopher. Each implied a form of agency. But both forms were understood to be socially restricted: Active citizenship was limited to adult male full members of the city; the philosophical life was even more limited to those who constituted the wise. Agency belonged to the few, not the many.

Medieval Christian thought turned away from human agency. Divine agency displaced human agency. The church condemned as heresy the view (known as Pelagianism) that people can achieve salvation through their own agency. Church doctrine insisted that salvation can come only through divine agency, with God's gift of grace. Boethius's *Consolation of Philosophy*, a book written ca. 524 and widely read for centuries thereafter, argued that all events and decisions are part of God's plan and derive from God's will. Boethius invoked the image of the wheel of fortune to argue that even apparent coincidences, chance, or luck are products of divine agency.

Renaissance humanism reintroduced a sense of human agency. The name *humanism* arose because of a greater emphasis placed on humanity rather than divinity, on human activities, and on practical rather than theological knowledge. Instead of being the subject of God's will, or powerless against the unpredictable forces of fortune, human beings can shape their circumstances and alter events. In short, in the humanist worldview, humans are agents.

Niccolo Machiavelli developed a notable conception of political agency. Wondering whether there was any scope for human agency in politics, Machiavelli argued in Chapter XXV of *The Prince* that fortune controls half the things we do, while we control the other half. Machiavelli goes on to

convey his idea of political agency with two metaphors. First, he compares fortune to a violent river that when in flood nothing can withstand. But even such an irresistible and destructive power can be mitigated by taking precautions such as building embankments. In this metaphor, the scope of agency is owing to the human quality of prudence or the rationality of practical foresight. Second, Machiavelli likens fortune to a woman, alluding to the Roman goddess *Fortuna*. But even the unpredictable and changeable winds of fortune can be mitigated by those who are adventurous, manly, strong, and audacious. In the first metaphor, the precondition of agency was cautious rational prudence; in the second it is self-confident power. In sum, Machiavelli offers a recognizably modern theory of agency: He estimates its scope (about half of what we do is agency, half is passivity) and he attempts to identify its bases (rationality and power).

### *Marxist Perspectives*

Marxism brought a distinctive theory of agency. Marxist thought was preoccupied not with everyday private agency at the micro scale, nor with the routine agency of politics, business, or war at the macro scale, but with agency as the collective pursuit of a social revolution. Agency in this context means transforming the world. It became known in Marxism as “making history.” Conceived in this way, agency is something that requires immense power, vast knowledge, and hugely ambitious goals.

The agents that make history are classes. Marx was hugely impressed with the immense achievements of the bourgeois class. The first part of the *Communist Manifesto* hails the vast changes wrought by the bourgeoisie. The bourgeoisie was a potent agent, but its achievements were to be as nothing compared to those of the proletariat. That is because the task of the working class was no less than to liberate humanity, and to abolish scarcity, exploitation, inequality, and oppression for good. What makes the working class a suitable agent for such a task? It is not primarily that the workers are exploited, since they are not the first subaltern class in history to be oppressed. It is first and foremost the potential *power* of the proletariat to control production that gives them world-transforming agency. For Marx, power over production is the basis of all power. But this agency also requires *intentionality*:

Marx was confident that the proletariat would come to hold the goal of overthrowing capitalism and building communism. Its further basis was *rationality*: Advancing knowledge, supplied by the science of critical political economy, would reveal the laws of motion of history, the nature of capitalism, and the preconditions of communism.

Even among Marxists, confidence in the power, purpose, and rationality of the working class eventually began to evaporate. A search began among Marxists for some alternative world-transforming agency. Several alternatives arose: (a) The *revolutionary party*: Leninists developed the idea of the vanguard party: Critics such as Trotsky charged the Leninists with substituting the agency of the party for the agency of the class. (b) The *peasantry*: Maoists hailed the guerrilla army and the peasantry as revolutionary agents. (c) *Colonial nations*: In the mid-20th century, Third Worldists posited the national liberation movements of the so-called oppressed nations as agents of world revolution. (d) *New social movements*: By the end of the century, Marxists began to debate whether social movements of the Left, such as the feminist or green movements, had taken over the role of the working class as world-transforming agency. Though each held fleeting attention, and though each was an agency in the limited sense, none proved to be a world-transforming agent. None of these would-be agents turned out in practice to have the world-transforming power or aims that the theory demanded.

Within Marxism there arose a tension between structure and agency. Marx put it that men make history, but not in any way they please. They make history only under circumstances derived from the past. In due course, Marxism developed two strands: a deterministic one that gave priority to structure and a more voluntaristic one that gave primacy to agency. The deterministic or structural strand emphasized the playing out of the inevitable laws of motion of history that would fell capitalism and drive humanity forward.

Likewise, within social theory more broadly there also arose a tension between structure and agency. One strand denied or downplayed agency. The other took agency as its starting point. The former was preoccupied with the problem of how social order arises. The latter concerned itself with how individual actions generate social phenomena.

## Application

Some contemporary applications have been highly critical of the notion that human beings are agents. A notable challenge to agency derives from postmodernist thought. Its critical attitude toward agency was partly inherited from French structuralist thought. Following the structuralist theory of language, postmodernism dissolved agency and gave priority to structures of discourse. Language or discourse was seen as an encompassing structure that produced its own speakers and authors. But postmodernist thought went farther than this. It challenged the bases of agency. One basis of agency is intentionality. Against intentionality, postmodernism tended to stress the fragmentation of any stable identity or sense of self that might formulate consistent intentions. Human beings are conceived not as coherent and purposive but as unstable and shifting.

Another basis of agency is power. A major theme of postmodernism was that power is not a resource of agents. Instead, it is a general, if covert, feature of discourse or knowledge that flows throughout society as capillaries flow blood through a body. Michel Foucault wrote of power as if it possesses agency, instead of agents possessing power. Power produces things—indeed it is the active producer of subjects. Agents are products of power. Power causes things to happen. Power acts.

A third basis of agency is rationality: Postmodernism was highly critical of rationality. One line of criticism was that rationality had no secure foundations. Another was that rationality is oppressive, being a constraint on creativity and imagination. Postmodernism mounted a many-pronged attack on the notion of agency.

But other contemporary applications have sought to defend the notion of agency. Social studies influenced by Anthony Giddens's thought stress the centrality of agency. For Giddens, social theory was at an impasse, trapped between the two poles of agency and structure. His theory of structuration aimed to transcend the impasse. Giddens's theory of structure stressed two key points. The first was that structures are not totalities; *structure* is not another word for "society" or "mode of production" or "world system." Instead, structures are specific sets of rules and resources. Societies or world systems consist of many overlapping sets of structures.

The second key point in Giddens's theory of structure was that structures are not just constraining but also enabling. They limit but also assist action. Thus, structure is not the means by which society limits the scope of what individuals can do. It is how multiple sets of rules and resources at times limit and at times aid agency. Giddens's theory of agency held that the main property of agents is power. Agency, in Giddens's view, means power. Intentionality is not a property of agency, he argues, because actions often have unintended consequences. This remains the most controversial part of Giddens's theory.

In theorizing the interplay of structure and agency, Giddens is keen to point out that neither is in principle more important than the other. As for their relationship, Giddens denies that structure and agency are two separate and opposed things; instead, both are aspects of a single process of structuration in which both structures and agents are involved in the ongoing production of further structures and agents.

A key issue in recent applications concerns what sorts of agents are currently influential in the world order. It is sometimes thought that in a context of globalization, states are becoming less important agencies compared to nongovernmental organizations (NGOs). Daniel Drezner has analyzed this issue in a set of case studies of international regulatory regimes governing the Internet, intellectual property, finance, and other domains. He concludes that the great powers (especially the United States and the European Union) remain the key agents in global governance.

## Critical Summary

The interplay between agency and circumstance has long been one of the central issues of social science. All of the human sciences have at root a similar subject matter: human agency as it occurs in structured domains and across temporal spans. Hence all case study research has a similar basic logic of situating agents and actions within its structuring contexts. This is likely to remain the case owing to the basic duality of the human condition: Human beings at once make their social contexts and are made by them; we are actors but also acted upon; people are

subjects and objects; in part we possess agency and in part we lack it.

## ALIENATION

---

The concept of alienation at work refers to a process and to the negative results that are produced in a worker who performs a routine, repetitive, and mechanized work that is little stimulating, and that presents the worker with limited possibilities of growth and development. An investigation carried out on alienation must acknowledge that it is a concept not easily defined, has similarities to other constructs, and is a complex phenomenon that requires the consideration of different methodological and conceptual aspects.

### Conceptual Overview and Discussion

Many have studied the notion of alienation at work. According to Karl Marx, work becomes alienating

when a worker is engaged in a series of tasks over which he or she has no control, and the worker is imbedded in a system of domination, constraint, and under the orders and authority of another person. Erik Erikson associated alienation with a lack of identity in the worker as a consequence of the conflicts between the individual and the social structure. Robert Merton refers to the notion of occupational psychosis as a consequence of the hierarchical inflexibility of organizations, producing an incapacity or incompetence in the worker. In the bureaucratic organization of Max Weber, the bureaucracy produces a climate of alienating work in which the worker should comply with the routines, strict obedience to the hierarchy, and compliance with the norm. Frederick Taylor utilized economic incentives to achieve the maximum productivity of work. The consequence of this was a type of work that was repetitive and in which the needs and motivations of the worker were considered irrelevant. This has been considered alienating.

The study of alienation at work has been undertaken more extensively to understand modern and industrialized societies through a focus on the labor, economic, political, religious, and social systems. The different notions of alienation discussed in the literature have focused more prominently on the condition of the laborer.

Studies of alienation at work have been carried out in many organizations, including industries, government, the health sector, and the education sector; in different occupations and professions such as health workers, teachers, employees, and professionals and nonprofessionals such as manual and nonmanual employees; through different perspectives, including sociological, economic, psychological, and in the social sciences. The notion of alienation has been associated with other constructs; for instance, job dissatisfaction, pressure, exploitation, syndrome of burnout, and mechanization. Alienation at work has its origin, chiefly, in the organization and produces direct and negatives effects in the worker.

Based on the social-psychological literature, Melvin Seeman proposes six meanings of the notion of alienation: powerlessness (feeling of impotence and incapacity to influence in the work system), meaninglessness (feeling of absurdity, lack of sense, and absence of meaning), normlessness (feeling of anomie, and absence of norms), cultural

estrangement (rejecting the values shared by the society), self-estrangement (auto-alienation and lack of interest in the work), and social isolation (feeling of isolation). Seeman stresses that some meanings of alienation are not clear (e.g., self-estrangement), and he notes that there are difficulties in clearly defining and assessing such meanings.

Walter R. Heinz identifies weaknesses in the analysis of Melvin Seeman's work and makes suggestions for future investigations of the notion of alienation. These include developing definitions and measurements of subjective dimensions of alienation; the need for case studies or the use of other research methods that will allow for the development of a deeper understanding of the process(es) by which workers experience alienation; addressing the lack of research with a simultaneous analysis of social and work contexts; addressing the lack of conceptual approaches of the dimensions of alienation; and addressing the lack of multidimensional approaches to measure and to analyze alienation. Despite the diverse existing criticisms, the contributions of Seeman have provided the foundation for the construction of multiple scales of measurement as well as the conceptual focus for the study of the alienation.

### Application

In this section, two cases are presented in which the authors performed investigation of work alienation using different methodologies. Both cases contribute interesting results and offer two interesting methodological perspectives for the study of the work alienation.

Margaret Vickers and Melissa Parris designed an exploratory and qualitative study using Heideggerian phenomenology to capture the lived experiences of 10 respondents through interviews. The respondents expressed experiencing alienation in different forms. The results of this study indicate that the respondents who were laid off or made redundant had an alienating experience, with feelings of powerlessness, shock, betrayal, humiliation, embarrassment, shame, and social isolation. According to the respondents interviewed, the outcomes of these experiences were trepidation and fear, less enjoyment, less confidence, less competence in their work, erosion of trust in organization and other people, and a negative impact on careers and families.

In another case, Melvin Seeman studied the consequences of alienation in a random sample of male employees in a Swedish community ( $N = 558$ ). The consequences included in this study were: intergroup hostility, anomie, political withdrawal, status seeking, and powerlessness. In this study, Seeman designed an index of work alienation using interviews with questions to discriminate among several work situations. The index of work alienation included seven items. Seeman also designed measures of outcomes of work alienation: generalized powerlessness, intergroup hostility, political awareness, status-mindedness, normlessness, expert orientation. In the validity processes, the author performed a factor analysis, and each variable was deemed reliable by the author.

In the first case, Vickers and Parris use the phenomenological approach because it is one of many types of qualitative research that explores the lived experiences of individuals. With this approach, the researcher systematically collects and analyzes the narrative experiences of employees. The authors analyzed the experience of work alienation as a consequence of having been laid off or made redundant. This study drew on a small sample size to foster an in-depth understanding of the experiences, feelings, and events lived by the respondents.

In his study, Seeman used a deductive method. He designed the instruments to assess work alienation (index of work alienation) and for other variables (consequences of the alienation at work). Seeman validated and ensured the reliability of the scales utilized. Because of the methodological approach used in this study, it was possible to consider a sample of greater size.

The discussion of these two case studies illustrates the use and availability of different methodological approaches to study alienation at work. The qualitative and quantitative methodologies offer valuable elements for the study of a phenomenon as complex as alienation.

### Critical Summary

Alienation is a theme that has been studied since the industrialization of societies. Alienation is a social and labor problem that exists in many countries, which presents an extensive opportunity to carry out research projects. Recently, many researchers have developed scales for the measure-

ment and comprehension of alienation in different types of organizations. In scientific research, the study of alienation represents a great challenge for researchers because of its complexity. This is seen in the various ways that alienation has manifested in various organizations and industries. Explanations of the concept of alienation require the use of quantitative and qualitative analysis to explain it in holistic and integral form.

## ANALYSIS OF VISUAL DATA

---

Visual data in case study research refers to any image that represents human experience, whether that experience is of the person(s) in the image, the experience of the image maker, or the experience of the viewer of the image. The photograph has been the dominant form of visual data, but other visual genres social scientists are using in case studies include videos, paintings, and collages. Given its predominance, this entry focuses largely on photography as an entry point into using and interpreting visual data.

### Conceptual Overview and Discussion

The development of mechanical reproduction of reality through the photograph lent itself to a scientific-realist view of the world, well captured in the expression, “the camera does not lie.” The scientific-realist view considered the photo as an exact representation of reality and as evidence rather than as an interpretation. Captions were often added to photos to direct viewers’ attention to what was “meant” by the contents of the photo. This view of the photograph, still used in documentary work, is diminishing in scholarly research. Photographers themselves recognized the differences produced through different camera settings as well as through the manipulation of the printing process, which is even more extreme given the current visual technologies available. Captions represent but one way of understanding a photo. Experience in the field highlights the role of theory and of restrictions governing the production of a photo, which ultimately shapes what is represented. The photograph, then, is not simply a “window” on reality, but rather an interpretation, one particular viewpoint among many.

Sources of visual data include archives and the production of images in the research setting itself. Archival images, which were produced for other purposes, can be interrogated as to their intended meaning in their time, how they were made, the content of the image including what is missing, their link to accompanying text as well as other texts, and how audiences over time have interpreted them. Occasionally, it may be possible to interview persons depicted in archival images, essentially creating an opportunity for photo elicitation, described below. Such scrutiny of archival visual data can produce important narratives that are counter to those espoused in the archival record.

Images produced in the research setting can be a powerful method for gaining new understanding since they are particularly suited to “seeing” people and social phenomena in a new light. Deeply held assumptions cause us to see things in a certain way; visual data are able to facilitate seeing differently. Photo elicitation and photo voice are two ways researchers can use photography to overcome their own assumptions in the research setting.

Photo elicitation is a variation of open-ended interviewing where photographs are used to elicit

the cultural insider's understanding of what is in the photo. The researcher, in taking photographs, comes to realize his or her lack of knowledge of what is contained culturally in the photo. Overcoming this requires, first, being self-aware: How am I approaching this situation and why am I photographing this particular content in this particular way? At the same time, it requires being an informed participant observer, where the researcher immerses him- or herself in the cultural world under investigation. Finally, having taken the photo, the photographer must now elicit from the cultural insider an understanding of what is in the photo and what was omitted. Roles are reversed as the researcher becomes the listener/student and the subject becomes the instructor. That which is taken for granted in the subject's world is explicated for the researcher, who often is unaware of what is "in" the photo. In this way, the voices of insiders are heard and the photo becomes an explication of their world rather than the author's limited understanding of that world. The subjectivity of those who inhabit the cultural world under investigation becomes more explicit.

Photo voice is a variation on photo elicitation. Rather than the researcher being the photographer, the cultural insider is given the means of production, thereby amplifying the voice of the insider. The insiders are given the power and the means of telling their story in a manner chosen by them, and the researcher becomes a collaborator in telling their stories. With the use of video technology, photo voice communicates even more. It becomes a way of conveying the felt experience of living in a particular cultural world in a way that goes well beyond what could be expressed through only words and still photographs.

The use of visual data in research is determined by several things. Central considerations include the research question(s) and theory used by the researcher, aptitude with visual methods, ethical considerations, and in archival-based research, the availability of images. Several of these issues are addressed in the discussion below.

### Application

Douglas Harper's ethnographic case study of a rural mechanic in *Working Knowledge* is a masterful example of the use of visual data produced in the research setting. Harper focuses on one

individual—Willie, and, in particular, his skill as a mechanic. Harper's study developed out of his personal, theoretical, and methodological interests. He came into contact with Willie, later his friend and key informant, through a mutual interest in Saab automobiles. The nature of the skill Willie displayed as he went about repairing Saabs as well as various other things was theoretically intriguing to Harper, especially as he saw that kind of skill disappearing with the increased rationalization and automation of repair work in Western society. Harper has a strong methodological interest and ability in photography and visual methods. Moreover, Harper has an abiding concern about the disappearing rural world in the face of continued modernization. Thus, photography became integral to the research project.

As he began the research, Harper took photos of Willie's work but quickly realized his photos did not reflect the depth of knowledge and skill evident in Willie's work. Harper took more photos, becoming much more sensitive to Willie's work—the hands, the materials and tools, the fine details, the setting, and the progress of the work. Then Harper interviewed Willie, making the photos the focal point of the discussion. He gathered 30 hours of tape-recorded interview material that he transcribed into some 300 pages of text. Through sensitivity and photo elicitation, Harper achieved an important transition in what his photos communicated.

The use of photography did not end with the photo elicitation. Past practice used photos as dressing to illustrate or supplement text, which was considered the "real" work. However, an ethnographic case study using photos would be impoverished if it did the same. Thus Harper sought to have the text *and* the photos explain the skills and community around the shop. *Working Knowledge* displays congruence between text and photo, and a dependence of one on the other to produce a coherent presentation. Displaying a series of photos juxtaposed with the verbatim transcription of Willie and the author talking about the photos provides the interactive element necessary for the photos to do the work of explanation. Readers are invited to participate in the interview and to grow in their understanding of Willie's world from Willie's perspective in Willie's own voice as they listen in on the conversation concerning the cultural meaning depicted in a photo.

It is important to note some ethical issues Harper encountered in utilizing photography. First, cameras are intrusive. To gather the photos necessary for his purposes, Harper needed to be quite aggressive; the detail in his photos bears this out. Photography is much more visible and invasive than standing off to the side taking notes. Permission must be granted, and not taken for granted, as the research progresses. Moreover, some topics may become too intrusive and personal for photography. Harper includes only a few photos of the connection of Willie and his shop to the wider community. The paucity of photos in this aspect of the research may underscore increased sensitivity and reticence in this area. Choices concerning when to use photography are dictated by the appropriateness of the research setting and relational context.

Second, photos are revealing. Anonymity of respondents is at stake. Though Harper uses a pseudonym, Willie's face is recognizable, and since Willie's reputation is critical to his everyday life, to show his face presents a significant risk. Also at stake is the misrepresentation of the photos, especially when removed from their context. Harper's attention to the inclusion of Willie's voice situates the photo and its production in its context, and the reader is moved from a foreign "other context" interpretation of the photos to an understanding from Willie's perspective. In Harper's text the reader is moved from seeing "junk" to seeing value and worth, community, and even beauty.

Several examples of archival visual analysis are also available. In her book, Catherine Kohler Riessman highlights two examples, one of which is the work of Elena Tajima Creef, who interrogates the visual depiction of the internment of Japanese Americans during World War II. Her work clearly shows the interplay of archival photos, texts, government documents, drawings, and the iterative nature of analysis—moving back and forth between photos and other data. Interestingly, Creef also draws on a corpus of photos from three different photographers who produced a record of Japanese internment from three different perspectives and agendas. Evident in Creef's analysis is the care taken to understand the photographers' "theory" in creating their photos, as well as the importance of attending to the contexts in which the photos were produced.

### Critical Summary

Visual data are increasingly being employed in case studies as the products of photography, especially, but also other visual genres, are conceptualized in ways that challenge the realism of traditional documentaries. Photo elicitation undermines the authority of the "expert" researcher in favor of the cultural insider. Photo voice undermines the power relations implicit in production of photos seen, for example, in the colonial era. The power of image-making is now given to the subjects of the research, who typically have not had the power or voice to represent themselves. The critical scrutiny of archival visual data challenges "official" stories, thereby surfacing counter-narratives. Overall, the postmodern turn in the social sciences has brought new life and vigor to the use of visual data, creating richer analysis and deeper insight as we begin to see in new ways.

## ANALYTIC GENERALIZATION

---

With both the case study and the laboratory experiment, the objective for generalizing the findings is the same: The findings or results from the single

study are to follow a process of analytic generalization. Analytic generalization may be defined as a two-step process. The first involves a conceptual claim whereby investigators show how their case study findings bear upon a particular theory, theoretical construct, or theoretical (not just actual) sequence of events. The second involves applying the same theory to implicate other, similar situations where analogous events also might occur.

### Conceptual Overview and Discussion

All research takes place in the form of single studies. The significance of any given study depends not only on the study's findings but also on the broader implications of the findings—the extent to which the findings can be “generalized” to other studies and other situations. The more that research of any kind is generalizable in this fashion, the more the research may be valued.

Generalizing the results from a single case study poses a unique problem. Case studies are typically about a specific case. Even if a case study is about multiple cases, each case is likely to consist of a specific set of persons or a specific set of events in a specific place and at a specific period of time. Indeed, each case's specificity is likely to make it a unique situation. Given these circumstances, how to generalize a case study's findings to other situations, thereby enhancing the importance of the findings, would at first appear to be problematic. Note, however, that the same challenge pertains to laboratory experiments, not just case studies. How to generalize the results from a single experiment, taking place with a specific group of experimental subjects in a given place and time (and subjected to specific experimental interventions and procedures), also might seem problematic.

### Application

Using analytic generalization requires carefully constructed argument. The argument is not likely to achieve the status of a proof in geometry, but the argument must be presented soundly and be resistant to logical challenge. The relevant theory may be no more than a series of hypotheses or even a single hypothesis.

The pertinent argument or theory should be stated at the outset of the case study, not unlike the

posing of propositions or hypotheses at the outset of any research. The argument needs to be cast in relation to existing research literature, not the specific conditions to be found in the case to be studied. In other words, the goal is to pose the propositions and hypotheses at a conceptual level higher than that of the specific case. Typically, this higher level is needed to justify the research importance for studying the chosen case in the first place.

The findings from the case study should then show how the empirical results supported or challenged the theory. If supported, the investigators then need to show how the theoretical advances can pertain (be generalized) to situations other than those examined as part of the single case study.

The procedure does not differ from that used in reporting the findings from single laboratory experiments. However, the procedure does differ strongly from an alternative strategy—statistical generalization—which is not relevant to case studies and should be avoided if possible.

An example of analytic generalization is found in Graham Allison and Philip Zelikow's famous case study of the Cuban missile crisis. The investigators initially posed their case study as one that would investigate how superpowers confront each other. The case itself involved the United States and the former Soviet Union threatening each other over missiles located in Cuba in 1962. After presenting their case study, the authors then claimed that similar lessons could be applied to a wide variety of other international confrontations involving superpowers, including confrontations from other eras and involving superpowers other than the United States and the Soviet Union.

### Critical Summary

As part of the case study, the stating and examining of rival hypotheses will greatly strengthen the claimed analytic generalization. Meaningful or plausible rivals to the initial hypotheses should have been identified at the outset of the case study (but also may be encountered during the conduct of the case study). Thorough examination of the rivals entails sincere efforts to collect data, during the case study, *in support of* the rivals. If such data have been stringently sought but do not support the rival, the rival can be rejected. Case study findings that support the main hypotheses while simultaneously

rejecting plausible rivals constitute strong grounds for claiming analytic generalizations.

Beyond making a claim, the generalizability of the findings from a single case study increases immeasurably if similar results have been found with other case studies—whether such studies already existed in the literature or were completed after the first case study. The replication of results across multiple studies, again whether occurring with case studies or with a series of laboratory experiments, is therefore a methodic and desired extension of the process of making analytic generalizations.

## ANONYMITY AND CONFIDENTIALITY

---

The concepts of anonymity and confidentiality are closely linked in case study research. Anonymity is the protection of a research participant's or site's identity. Confidentiality is the safeguarding of information obtained in confidence during the course of the research study. It may be oral (i.e., obtained during an interview) or written (i.e., obtained during a review of an individual's or entity's records and other documents).

### Conceptual Overview and Discussion

Case study research is often used when a researcher is looking for in-depth, detailed empirical data

about a particular phenomenon. Data may be gathered using a case study to develop a theory, test an existing theory, or obtain a more in-depth understanding of themes emerging from quantitative studies using surveys. Data concerned with matters of public interest may also be gathered. The researcher must take every means possible to protect the identity of the research participants and preserve the confidentiality of information obtained during the study. The confidentiality requirement is no less stringent when the research site operates in the public domain (e.g., a publicly traded corporation) or when information about research participants and sites is available to the public through alternative sources.

The need to maintain the anonymity of the research participants and site and the confidentiality of information can create ethical and methodological challenges for the researcher at various stages of the research process. These challenges are discussed in the following sections.

#### *Ethical Considerations*

Individual participants in a research study risk possible loss of anonymity, and this risk increases in studies using qualitative research methods such as interviews and observation. The loss of anonymity can lead to personal embarrassment and a possible loss of self-esteem and employment for the participant. Entities that are used as research sites can also suffer from a loss of anonymity, leading to damage of public reputation or disclosure of trade secrets, for example. In her landmark study *Men and Women of the Corporation*, Rosabeth Moss Kanter identified her research site by a pseudonym—INDSO—in order to protect the identity of the organization and its employees.

Protecting the research participants' identity does not, however, eliminate the need to protect information obtained during the research that may be of a confidential nature. Publication of confidential information can, inadvertently, lead back to the identity of specific individuals. Research participants can overlook or forget that information they are providing to the researcher is not known or generally available outside of the research site. For example, they may discuss information obtained from the entity's intranet site concerning new product development, acquisitions, or investments

that have not yet been made available outside of the entity, or specific personnel matters or individuals. It is the researcher's responsibility to ensure that this type of information is not published even when it might represent a significant component or aspect of the research study. If such information is disclosed, it is the reputation of the researcher and potentially the researcher's institutional affiliation that is damaged.

Privacy and confidentiality form one of the major cornerstones of the ethical research policies concerned with the use of human subjects in research. Research ethics boards (REBs; Canada) and institutional review boards (IRBs; United States) have been established in academic institutions as well as other entities engaged in research of and using humans. Researchers must receive approval from the relevant committee prior to conducting the study.

In their application to their REB or IRB, researchers are required to describe how they will maintain the anonymity of the research participants through the use of pseudonyms and the publication of general rather than specific descriptions of demographics. They must address the physical safeguarding of data, for example, interview tapes and transcripts, restriction of access to the data, and methods of destruction upon completion of the study. Finally, the researcher must indicate whether any of the research data will be disclosed to third parties. All of these procedures are designed to maintain anonymity and confidentiality. In practice, researchers may be required to seek approval from more than one board or committee, particularly if their research involves educational (e.g., elementary and secondary schools) or healthcare institutions (e.g., hospitals) and their constituents. Failure to obtain the necessary approvals can result in the cancellation of the study.

### *Methodological Challenges*

Case studies often focus on how people live their lives and act in particular, situated contexts. The removal of identifying information and suppression of confidential information can lead to the removal of the contextual information that is of the greatest interest and value to the researcher. Thus the researcher is faced with the challenge of presenting significant findings from a study while

maintaining the anonymity of the participants and preserving confidential information. This challenge can be compounded when the case study involves a small number of participants; the phenomenon under investigation is limited to a small community; or a third party is intimately familiar with the researcher's work or the research site (entity and individuals). The generalization or removal of certain identifying characteristics does not always remove the risk of identification nor reduce the risk related to the publication of confidential information. In some situations it may be necessary to omit any reference to the individual or entity.

Clifford Christians notes that despite all efforts on the part of the researcher, the maintenance of watertight confidentiality is almost impossible to attain. Insiders may recognize the pseudonyms and disguised locations. Information perceived as harmless by the researcher may, in reality, be perceived quite differently by the participants. One suggested approach to mitigate this risk of identification is to engage the participants actively in the drafting of the research findings. At the same time, the researcher must balance the need to protect the participants with the need to maintain the integrity and value of the study.

### **Application**

In her study of women managers leaving their work organizations, Judi Marshall conducted in-depth interviews with 17 participants. One participant subsequently withdrew during the final phases of the study because of her articulated concern that she could or would be identified. Gloria Miller noted in her study of women working in the Canadian oil patch that it was necessary to remove any identifying characteristics (e.g., position title, description of organization, location of employer, nature of involvement in the oil industry) because the Canadian oil industry was densely interconnected. That is, the industry was a small, geographically concentrated industry where networking was prevalent and individuals moved among the companies. This created a risk that someone familiar with the industry would be able to identify one or more of the participants in the study.

In a study of the careers of women accountants conducted by Peggy Wallace, several participants spoke freely about the challenges encountered

while working in public accounting firms. Their challenges ranged from the time demands and commitments of the profession and public accounting firms to lack of support from identified members of a firm. In one case, a participant provided financial information about a firm in order to illustrate the magnitude of her challenge. While this was exactly the type of information the researcher was looking for, the financial information could not be used as it was not known or made available outside of the partnership. It also proved to be very difficult to mask the identity of the participant without losing the context and value of her particular story. Because of concerns about the possibility of someone identifying this individual, a decision was made to exclude her detailed story from the study.

### Critical Summary

The very characteristics that make case study research valuable in terms of providing insights and in-depth information about a particular phenomenon are the same characteristics that create ethical and methodological challenges concerning anonymity and confidentiality. The researcher who uses case studies must always deal with these challenges and balance the value of publishing the research findings against compromising the anonymity of the participants and information provided in confidence. There is no easy or simple way to resolve these challenges. The researcher must address the issues as they arise and take appropriate steps to resolve them to everyone's satisfaction. At the same time, researchers should not avoid case studies due to the existence of these challenges.

## ANONYMIZING DATA FOR SECONDARY USE

---

Anonymizing data is a process that occurs throughout the data collection and analysis phases of research where identifying information is removed from the data in order to protect the privacy of research participants, the groups and/or communities that are being examined. The process of anonymization helps to prepare the data for secondary use where it is made accessible to other researchers. Secondary use refers to using data to examine a question that was not the purpose of the original data collection.

### Overview and Discussion

Data anonymization is an important stage in the research process, especially when preparing the data for secondary use. Anonymizing data may involve several levels and there are many ways it can be achieved.

The first level often involves removing or renaming direct identifiers. For example, anonymizing data involves more than simply removing the names of the participants under examination. It also involves removing or substituting all of the elements (e.g., names, places, and addresses) that might lead to the identification of an individual or group under examination. This can be done by giving all participants or cases a pseudonym or a code number. Some may argue that it is better to use numbers instead of pseudonyms in order to avoid the possibility of switching one person's name with that of another participant within the same case study. Numbers may offer protection against

revealing participants' identity, but they do seem somewhat sterile. In using pseudonyms, it may also be important to give participants names that are appropriate to their generation. A good strategy might be to go to the most popular names from different years to find suitable names. If the researcher feels confident that it is not to the detriment of anonymity, it might be useful to choose a name that starts with the same letter—Jack to Joe for instance. This then might help when analyzing the data and keeping in mind the person rather than just his or her words.

Establishing pseudonyms early in the research process is helpful. Changing the names when first proofreading the transcripts provides space to become familiar with the pseudonym. The point is to keep the data alive and, at the very least, associated with that person but not identifiable. It is also important for the original researchers to keep a cross-referencing system, which is needed to link original names to the data.

The second level involves removing or renaming indirect identifiers. A common technique involves restricting the more extreme or deviant cases, particularly within qualitative data. Another approach is referred to as *bracketing*, where categories of a certain variable, like age and income, are combined. For example, birth dates should be converted into age categories. Other indirect but specific personal information that could identify participants could be anonymized in the same way. Another strategy is to collapse or to combine variables by creating a summary variable. Within qualitative research, anonymizing is often more difficult because many identifiers will often need to be removed. Depending on how small the case study is, certain places may also need to be renamed in order to protect the anonymity of the community under investigation.

Finally, at the third level, researchers need to decide whether their data are simply too sensitive to be made publicly available. The data may be deemed so identifiable that they cannot be made publicly accessible for secondary analysis.

In all cases it is important for researchers to establish a systematic procedure for replacing, bracketing, or deleting text. It is also a good idea for researchers to keep a list of all of the items that were replaced or removed. Researchers may find it worthwhile to proofread the data to develop a sense

of what needs to be anonymized. All of the researchers involved in the data collection should be involved in the data anonymization process because each has a different idea of what is important to preserve for secondary data use. Researchers should also ensure that a copy of the original data be kept.

### Application

When working with sensitive or marginalized groups, ensuring that participants' identities remain hidden might need to take precedence. People can be identified through habits or pastimes and not simply by their names. The ability for others to backtrack and potentially establish the identity of a participant could be through obvious examples, such as highest qualification or a rare incident. Such information, while seemingly innocuous, might be the key to personal identification if the participant is part of a small group or close-knit community. Other group or community members may be aware of the indirect identifiers and be able to make the necessary connections back to the individual. At one level, it may be necessary to make subtle changes in such information or at the extreme remove it all together. For example, in a study exploring health literacy in gay men, three small groups were accessed and participants recruited. A participant within one group was the only person to hold a PhD, whereas others held master's degrees. In this example, it was necessary to change the name, age (making him a year younger but still in his early 40s), and all mentions of degree to "higher degree." This did not substantially alter the context of the data but did set in place safeguards to protect the anonymity of the individual as his identity blended in with the others with a higher degree.

On other occasions, it might be necessary to remove sections of the data where the indirect identifiers cannot be altered in ways that guarantee anonymity. For example, in Paul Bellaby, John Goldring, and Sara MacKian's study of health literacy and the framing of health messages in the gay community, the eating habits of a participant's mother-in-law were so revealing that no amount of anonymization could have concealed the identity to his partner. Of course, revealing the eating habits was not the problem, it was the associated data, which revealed serious health problems. A judgment

needed to be made between the data/analysis and the promises of anonymity. Had the data not been removed, it would have been easy to backtrack and identify the individual. In both instances above, the participants were given a copy of their anonymized transcript along with a list of what had been removed and the rationale for its removal. They were then asked if they felt their anonymity had been protected.

When sampling from small groups or communities, identifying features could be the specific activity from which the group is formed. For example, Bellaby, Goldring, and MacKian recruited participants from a gay rugby club. This is an activity with a highly specific indirect identifying feature. In this instance there are three levels of concealment to consider: the identity of participants from other group members; the identity of the participants from the wider population; and finally, the identity of the group. The group was labeled “athletes,” which kept their sporting connection but hid the actual activity. It was then necessary to bracket out the specific activity from the transcripts. The same standard of anonymizing the data was still required so that other group members could not identify each other. In this instance, it was necessary to collapse and combine the narratives of participants so that the analysis of the group was referred to when presenting the subsequent report.

### Critical Summary

Anonymizing data for secondary use involves telling the story of what is happening within a case without telling whose story. Important benefits include protecting the identity of the research participants, saving time and money by avoiding the collection of similar primary data, and creating an opportunity to develop a better understanding of a phenomenon that was unpredictable at the time of the original data collection. For example, some of our understanding of the causes of disease can be attributed to secondary data analysis.

Disadvantages of anonymizing case study data include that it may distort the data when contextual factors are removed. It is also often difficult to know how much anonymization is enough. Anonymizing data may make them more difficult to link with other data. Finally, ethical issues also

need to be considered. For example, did participants give informed consent for others to use the data for reasons other than the initial purpose of the data? There are also issues about who has ownership of the data once they are open for other researchers to use.

## ANTI-HISTORY

---

ANTI-history is an approach to the study of the past that draws on actor-network theory (ANT), poststructuralism, and the sociology of knowledge. ANTi-history sets out to simultaneously represent and destabilize selected past events with the ultimate aim of pluralizing history.

### Conceptual Overview and Discussion

ANTI-history, developed by Gabrielle Durepos and Albert J. Mills, draws on poststructuralism,

the sociology of knowledge, and ANT to make sense of the past. The approach developed out of an interest in how knowledge, particularly historicized knowledge, comes into being and influences human action. The interest in knowledge is rooted in the concerns of the sociology of knowledge to understand the social base or roots of knowledge. The interest in history is rooted in the concerns of Foucauldian poststructuralism to understand the ways in which the present is constructed through reference to past events, that is, that history can be seen as a study of the present rather than of the past. To trace the social bases of present knowledge, Durepos and Mills draw on ANT, which seeks to reassemble the present through tracing the sociopolitics of actors over time by focusing on the way networks of ideas cohere, or are punctuated, in forms of knowledge. Building on Bruno Latour's ANT, Durepos and Mills set out to fuse together insights from the sociology of knowledge, poststructuralism, and ANT to develop a historiography that is capable of dealing with the past as "available" through innumerable traces whose construction lends itself to equally innumerable histories. As such it is a method for simultaneously assembling and destabilizing histories. In other words, it is an approach that encourages the development (or reassembling) of historical analyses, not simply to represent the past but also to reveal alternative readings (or histories) that surface that which is marginalized, hidden, suppressed. In the process, histories are revealed as useful guides to human action at the same time that they are destabilized by an understanding that they are reassembled for current action rather than grounded in fact. Hence the term *ANTI-history*, which draws on the signifier of ANT to signal a link with actor-network theory and that suggests the tension between the simultaneous construction and destabilization of history projects.

### Application

Above all else, ANTi-history is a liberationist project aimed at revealing the social bases of knowledge, particularly knowledge that has the added significance of being punctuated as history. In this way, people can become aware of the sociopolitical role of history and its significance in the creation

and privileging of identities. To that end, an ANTi-history approach involves a number of processes that include critique of existing histories as partial and, in the words of Hayden White, invented rather than found, and in the reassembling of alternative histories that simultaneously bring to the fore previously marginalized voices and destabilize existing history as one of various alternative readings. The approach thus is far reaching and requires considerable time, commitment, and access to relevant actors and materials.

An example of ANTi-history can be seen in the recent work of Durepos and her colleagues on the study of Pan American Airways (PAA). This airline was in operation from 1927 until its collapse in 1991. In its day, it had a powerful influence on the culture as well as the economy of the United States. Much of this had to do with the sociopolitical role of the airline over time but was also helped in later years by a series of histories of the airline that kept, or perhaps revived, its influence in popular culture. Examination of the various histories presents a fairly coherent story in terms of the main characters and events involved. The main difference between the histories centers on the attention given to some events over others and the time in which they were written. The earliest history of PAA, for example, was published during World War II and focused more on the heroic contribution of the airline to the war effort. Later histories give more time and attention to different decades and events beyond the war years.

Reading the various histories from an ANTi-history perspective requires detailed notation of highlighted characters and events (using a form of content analysis); analysis of the organizational discourses that appear to be embedded in the materials discussed (using critical discourse analysis); analysis of the relationship between each text's author(s), the context in which they are writing, and the intended audience (using critical hermeneutics); and an interrogation of the various texts to see who and what is privileged and who and what is marginalized, hidden, not discussed. In this particular case, PAA histories privilege men over women, whites over people of color, U.S. citizens over people of other nationalities; some form of benevolent U.S. imperialism over other forms of imperialism; technology over tradition; entrepreneurship over bureaucracy; and private ownership over public

ownership. In the process, women and people of color are marginalized and barely make their way into the story. The peoples of Latin and South America are marginalized in some cases (e.g., as plot devices to reveal the skills and intelligence of PAA's managers), hidden in most cases (e.g., with the story focusing on PAA's ability to expand its airline through acquisitions and deals), or demonized (e.g., as in stories that range from attempts to obstruct PAA's expansion in South America to threats to U.S. interests in the Panama Canal).

In the development of a case study of a particular person, organization, or event, written histories are but one important source of material in the pursuit of an ANTi-history. Access to the selected person or members and former members of an organization are also important as is access to archival materials. In the case of PAA, entry to the organization was impossible as the company closed in 1991. This made access to former employees very difficult if not impossible. However, there does exist an extensive archive of over 1,500 boxes, housed at the Otto Richer Library of the University of Miami. The latter allowed Durepos and her colleagues to examine numerous historical "traces" to scrutinize not the extent to which existing histories of PAA were based on selected readings of materials (that is taken as a given), but the sociopolitical processes that shaped those readings.

A number of findings have been developed from the emergent ANTi-history of PAA and have been written about elsewhere. They include the development of a prominent story of myth-like proportions that positioned PAA and its leaders as heroic in the World War II struggle against the Nazis. It is a story that constructs the Colombian state as Nazi collaborators, or at best opportunists, in what is characterized as a German threat to U.S. interests, specifically the Panama Canal. Through a detailed sifting of the PAA archive and other materials, Durepos and her colleagues were able to conclude that the myth of the German threat was only a partial reading of events. Moreover, the construction of the myth can be tied to a series of sociopolitical actions that preceded World War II but were punctuated by the onset of war, which served to "confirm" and "legitimize" previous conjecture. An alternative, but also partial, reading of events suggests that the myth of the German threat, built on a combination of xenophobic fear of strangers

and an organizational drive to establish a monopoly situation, served to encourage the U.S. State Department to ensure PAA an unimpeded expansion throughout South America.

The outcome of this and other studies of PAA is to destabilize existing histories not by showing that they were based on partial readings of events but that any history is based on a partial reading of events and is shaped by the sociopolitical contexts in which the historicized subject and the historian were located.

### Critical Summary

The development of ANTi-history is in its infancy and is designed not to replace existing mainstream histories with alternative, for example, feminist, Marxist, or postcolonial, histories but rather to encourage stories of the past that serve to destabilize existing histories and surface the marginalized, the hidden, and the denigrated in history. This does not mean the end of history per se but rather a pluralizing of historical accounts that recognizes and celebrates the problematic nature of history and its link to knowledge, power, and identity. It involves a careful balance between developing histories that do not, in the process, privilege history in the development of cultural knowledge of all kinds. It involves the careful development of storytelling that serves to tell a tale without telling *the* tale. It involves giving voice to a plurality of voices without deemphasizing any of the voices. It involves surfacing hitherto marginalized voices through histories that simultaneously legitimize those voices while delegitimizing the project of history itself. These are all serious challenges to the acceptance and viability of ANTi-history but, arguably, well worth the effort.

## ARCHIVAL RECORDS AS EVIDENCE

---

Archival records are an invaluable tool of data gathering for case study research that is focused on the past and its impact on the present. The careful analysis of archival records can provide valuable information on the life, concerns, and aspirations of individuals and groups, as well as on the activity, structure, mission, and goals of associations, organizations, and institutions.

### Conceptual Overview and Discussion

Archives mostly consist of personal and/or public written documents, maps, and official and private letters, but more recently also of audio- and videotapes, and Internet-based materials have also been included among archival records. For centuries, archives have been gathered, preserved, managed, and analyzed by kings, local and national governments, religious organizations, the army, the courts, the police and the intelligence services, universities, communities, associations, and even individuals. Moreover, the secret archives of the East German intelligence service (the political police popularly known as the Stasi), which has been open to the public since 1991, included about 15,000 transparent jars containing small samples of interrogated victims. To facilitate easy access and analysis, and in order to protect original documents from damage resulting from their frequent use, some

larger archives have started to transfer their written records onto microfiche or electronic support.

Archives whose records are neatly catalogued are easier to access than collections that are not, or are poorly organized. This is especially important for larger archives, where browsing can be time consuming, tedious, and expensive, without guaranteeing an interesting find. By granting access to only a fraction of documents, uncatalogued archives allow for interesting exploratory work, but not for a broader understanding of the activity, structure, and goals of the individual, group, or organization that produced them.

### Application

When using archival records as evidence, a number of questions need to be raised. Serious limitations can affect the nature of the questions researchers try to answer and the reliability of their final research results. Some limitations can be mitigated by collecting additional information from sources independent of the archives initially consulted. Other times, however, researchers will need to reformulate their research question to take these limitations into account, and to be aware of the limited generalizability of their research results.

First, questions must be asked about the archival record under consideration. Is the archival record genuine? If not, which of its sections, paragraphs, sentences, or words cannot be dated with precision, and which ones appear to have been modified (added, deleted, altered) at a later time? The history of the record, as pieced together from independent sources and the archive holder, is a good starting point to ascertain how much of the record is genuine, and when (and sometimes even why) changes to it were made (by adding handwritten comments or deleting some words and paragraphs). An archival record will have to be dated, a process that can be difficult as not all archives were fully catalogued, and can result only in educated guesses, as the record might include no indication as to the time when it was produced.

Second, researchers must be aware that not all archives were systematically collected. Some of them do not include many relevant documents, either because those documents were destroyed intentionally or accidentally or because they were scattered among other archived collections. For

example, like most other individuals, celebrity or ordinary folk, Beethoven did not collect all of his personal documents throughout his life, likely because he did not intend to make them available to posterity, because the task would have taken up valuable time he could dedicate to his music, and because by the end of his life the archive would have become too large and cumbersome to access, use, and move around. The digital archive of the Beethoven House in Bonn makes around 26,000 pages of handwritten music sheets, letters, first editions, pictures, and objects available to the public, but these archival records represent just a fraction of all written documents produced and collected by the composer throughout his life. A biographer researching Beethoven's life must thus be careful to supplement this archive with information collected from other sources.

Third, archive producers and/or custodians sometimes willingly destroy or hide material that would reflect negatively on them, their organization, or their country. In 1989, for example, secret agents of the Stasi shredded nearly 45 million sensitive documents, which filled about 16,000 plastic bags. Since the collapse of the Eastern European communist regimes, many intelligence service secret archives have been modified through the destruction and alteration of original documents and the addition of newly fabricated material aimed at hiding the past collaboration with the communist secret political police of prominent postcommunist politicians or to blackmail innocent citizens by portraying them as former secret informers. Many secret documents include handwritten annotations that cannot be precisely dated. According to credible reports, files detailing the activities of victims of communist repression were modified in order to present those persons as victimizers and thus reduce their chance to be elected to parliament. Eastern Europe alone grants citizens, historians, and researchers access to significant sections of its secret archives, but the extant archives differ significantly from the archives as they were in 1989, and as such they should not be accepted uncritically.

Governments and organizations around the world generally do not grant access to their recent documents, and they often keep at least part of their archived records hidden from public sight. Usually, documents produced in the past 30, 50, or 70 years

are not made available in order to protect the individuals who are still living and might suffer if their past actions were publicly exposed. This is the case even when the individuals were involved in human rights abuses, as were junta members in Latin American countries. Even in Germany, where citizens have access to a larger number of documents produced by state agencies than anywhere else, the records of the military intelligence remain classified, as they are throughout the world. Not only governments protect sensitive data. Over the years, several Swiss banks have refused to grant access to information on the accounts and deposits of Holocaust victims, although that information would have helped relatives to recover lost family fortunes.

Last but not least, it is important to remember that the reality as reflected in the archived records might differ from the reality as experienced by the people who lived it. Archival documents often reflect the reality as perceived by the organization or government that produced them. Repressive political regimes monitored a wide range of small social and political trespasses (like telling political jokes) of individuals who did not consider themselves political dissidents or opposition leaders. As Garton Ash explained, as a foreigner visiting East Germany he was perceived as a threat to the communist regime and placed under strict surveillance, although he met people not to spy but to research his doctoral dissertation. A "thick analysis" considering the political and social characteristics of that time and place is a must in order to understand each actor's role in the society. Archival records can be used as evidence only if the researcher knows the historical context in which a record was produced.

### Critical Summary

Archival records are an important source of information that scholars in the social sciences and humanities may rely on for case study research. When used systematically together with information drawn from other independent sources, archival records can shed light on the past and its relationship with current events, and can help us to understand the activity, aspirations, and goals of individuals and groups, and the organizational structure, mission, and objectives of associations, organizations, and state institutions. Researchers

must be aware of the possible limitations related to format and the content of the archival record, and use thick description to contextualize the social and political setting in which the document was produced.

Her seven functions of a narrative are tied explicitly to the narrator’s intended audience. First, Riessman points out that remembering the past for a particular audience is the most common use of narrative. It is the meaningful retelling of events to someone who may not have been there. Second, narratives are used to present an argument. Narrators present a narration in order to illustrate a point they are trying to articulate. Third, and related to the previous function, narratives can be used to persuade a skeptical audience to accept a particular truth. Not only will narrators present their point of view through a story, but they will also try to get the audience of the narrative to agree with them. The next function Riessman describes is the engagement of the audience into identifying with the narrator’s experiences. This is an emotional aspect in that the narrator wants the audience to “buy into” what is being told. Fifth, narratives can be entertaining. Riessman says that this is one of the most overlooked functions in academic circles, but it is probably one of the most common reasons we tell one another stories in a conversation. The sixth function can be the use of a narrative to mislead an audience. A false story could be told so that the audience does not discover a particular “truth” about the narrative itself. Lastly, narratives can be employed to instigate social change. Personal stories can be told in order to make the personal political, so that people will take up a cause.

### Application

Riessman applies this understanding of audience in her case study of two men’s illness narratives. In this study, Riessman demonstrates how, within each narrative telling, the men are developing and performing their narrative in a way that makes it obvious that the audience is taken into account. Her first case, Randy, demonstrates how the audience is important in realizing which narrative self is performed and at what point in the interview. Two examples of this include (1) how the researcher’s obvious discomfort with discussion on exploring homosexual identity steered the narrative in a potential new direction from where Randy would have wanted to go; and (2) how as an academic Randy felt comfortable critiquing the interview process, including that there was an insufficient

---

## AUDIENCE

---

Building on the foundations of Erving Goffman’s dramaturgical theory, narrative researchers recognize that the narratives we tell are not simply individual endeavors but social ones where we present ourselves to another. Narratives are constructed and performed with the audience in mind. Because of this dialogical element, we may not be able to know the “subject” or “experiences,” but solely the narratives.

### Conceptual Overview and Discussion

As Catherine Kohler Riessman indicates, the function of narratives revolves around the audience.

amount of tape for him to tell all he wished to tell. The second case, Burt, shows how the desire for companionship from the audience, and to reinforce a masculine working-class identity in the face of disability, become central to the narration. This is a heroic tale of survival in the face of many disruptions to Burt's identity (divorce, illness, loss of employment). With a female audience, both narrators construct a masculine narrative that takes this into account.

Andrea Doucet's narrative interpretation of fathers as primary caregivers points to the importance of an epistemology that looks at narratives rather than experiences or subjects. Among her participants were some men who wanted to be sure that the audience knew the sacrifices made in order to look after their children. The sacrifices of leaving paid work and becoming the primary caregiver (very nonmasculine decisions) were often made when the mothers left the home (there were a range of respondents, including stay-at-home fathers, single fathers, divorced fathers, and those with joint custody). The narratives seemed constructed and scripted with the audience in mind. Much like Riessman's case study of Burt, the narrative became what Doucet calls a "heroic narrative" whereby the story is told about the great obstacles the fathers had to overcome, both in the past and present, just as those heroes found in myths. Doucet examines the case of Mick, a primary caregiver. His narrative is ripe with examples of the hurdles he had to rise above in order to provide care for his daughter. Mick constructed and performed a heroic narrative intended to draw upon the audience's emotions and perhaps to couch his situation, stereotypically not masculine, in masculine terms for the female researcher. While not explicitly exploring the notion of audience, Doucet's case of a heroic narrative shows that the researcher, as an audience, is taken into consideration when a person tells his or her narrative. This reinforces the argument that narratives are not just individual's stories but are socially constructed and dialogical.

### Critical Summary

When looking at case-centered research methods that seem very individualistic, such as narratives, it is important to realize that an individual's telling of experiences and events has a social element.

Narratives are socially constructed and meaningful, which means that they are constructed for someone to hear at a particular place and time. This goes beyond Goffman's theoretical understanding of the performance of self, as narrative researchers' awareness incorporates not only the individual but also the social structures and relationships that surround the narrative.

## AUDIOVISUAL RECORDING

---

The ability to record sound and moving images offers an exceptional asset for case study research in such areas as language development, education, or medicine. Recent audiovisual technology has overcome the primitive and cumbersome aspects of early recording devices. Among these advances is the development of digital repositories that can store vast quantities of audiovisual data for access by large numbers of researchers.

### Historical Beginnings

With the prevalence of television, portable media players, and audio- and video recorders, it is hard to imagine a world that lacks the ability to record speech, music, and visual motion. Yet the phonograph and the movie camera are only over a century old. These early devices were primitive by today's standards. Their value for single case research was nevertheless recognized early on. Experimental photographer Eadweard Muybridge,

for example, was commissioned by Leland Stanford of California in the 1870s to document the motion of a race horse so as to determine whether all four feet left the ground simultaneously. Muybridge's success, through a technique of using multiple cameras in fast succession, influenced Etienne-Jules Marey in France to invent a single camera that could take 60 images per second. Marey's motivation was his research on animals. With access to the individual film frames, he published his results on physiology and locomotion in scientific journals. For most of the world, however, his invention was linked to entertainment and the motion picture industry, although Harvard Professor Hugo Münsterberg also foresaw the educational potential of film (then called the photoplay).

In the realm of audio recording, almost immediately after Thomas Edison developed the phonograph in 1877, the musicology community seized upon this new technology to support the field of comparative musicology. Thousands of cylinder recordings were made by multidisciplinary teams of anthropologists, sociologists, psychologists, ethnomusicologists, and musicologists across many countries. Such collections have been preserved in Britain, Germany, the United States, Canada, and elsewhere. The recordings faithfully represented temporal nuances, in spite of noisy acoustic quality. The most well-known collector was Austrian musicologist Erich von Hornbostel, first director of the Berlin Phonogram Archive. Once accessible only to researchers living in or visiting Berlin, the recordings are being made available digitally over the Internet or on compact disks.

### Application

The Harvard psychologist and assistant professor Roger Brown was among the first to use high fidelity tape recording for case study research. He and his students visited three children, named Adam, Eve, and Sarah, regularly for over a year. The researchers recorded discourse with each child and then faithfully transcribed the records for analysis. Common patterns of language acquisition were found across the three children, although the absolute onset of acquisition of various language skills varied. The data refuted a reinforcement theory for language acquisition. For example, correction of poor grammar or praise for correct grammar had

little effect. The painstaking data transcription and analysis revolutionized the psychology of language by providing a new foundation for the field.

Subsequently, Brian MacWhinney and Catherine Snow proposed a computerized library for discourse research whereby transcripts could be shared across researchers. In 1984, CHILDES, the Children's Language Data Exchange System, was born to house the transcripts of discourse obtained through research. The system eventually included a coding system (CHAT) and an analysis system (CLAN) that researchers needed to learn in order to use the database to store or analyze transcripts. CHILDES enabled researchers interested in similar questions to share the data without each having to collect it independently. The system proved useful, with over 100 researchers entering their linguistic data, leading to more than 2,000 research publications by them and others who accessed the database. Whereas CHILDES originally stored text transcripts, more modern technology has enabled storage of the sound files themselves. Further technological development has led to the possibility of storing video records, also valuable to psycholinguistic research, for example, for representation of facial expression, gesture, interpersonal relations, and environmental context. The TALKBANK project followed upon CHILDES as a repository for audiovisual records of conversation and communication, of both humans and animals.

More recently, an even greater level of linguistic detail is being recorded for a single case, the child of two academic parents. The father, Deb Roy, heads MIT Media Lab's Cognitive Machines research group. The mother, Rupal Patel, directs the Communication Analysis and Design Laboratory of the Department of Speech-Language Pathology and Audiology at Northeastern University. This Human Speechome Project creates the most comprehensive record of a single child's development to date. Virtually everything that the child sees and hears in his home is recorded minute by minute, thus providing a record of the environmental stimulation potentially influencing language development. The system includes 11 motion-activated video cameras, and 14 microphones. The data are transferred for storage to a bank of 10 computers with a high storage capacity that are kept in the house. When the capacity is filled, the data are transferred to a larger facility at MIT, freeing the

space at the home base. The amount of data available for analysis exceeds the capacity of even a group of human researchers, so semi-automatic data coding methods, referred to as TotalRecall, have been developed. From this single case, general principles of language development are expected to emerge that may determine the extent to which semantic and syntactic acquisition arises from exposure to specific incidents of speech.

Audiovisual recording also facilitates educational research. Researcher Victoria Armstrong and teacher Sarah Curran have reported a study of four teachers' incorporation of interactive (touch sensitive) whiteboards for class use. In this study, for each of three different one-hour segments of teaching by each of the four teachers, two video cameras were employed to focus on the entire class and its object of attention (e.g., the teacher and the whiteboard). The two video streams of information were played back on a split screen and the transcript of all important speech was superimposed on the screen. A videodisc was made of this information and each teacher was asked to review the videos of his or her class and to select the most important segments for discussion. The researcher viewed all of the videos. At a later stage in the project, a software package was employed to assist with coding such that each label used had a separate parallel timeline. Discussion of entire patterns of parallel annotations by researcher and teachers led to an overall understanding and interpretation. The outcome was the enabling of new ways of thinking about the complexities of classroom practice.

A comparable example in a medical setting is the use of continuous video recording of nurses tending to patients with a particular illness. A study by Christina Andersen and Lis Adamsen revealed both effective and negligent behavior of nurses in the context of the reactions and behavior of five cancer patients. The nurses, for example, communicated about physical care rather than the psychological needs of the patients, supporting initial hypotheses tested by the research.

### Critical Summary

Whether in developmental psycholinguistics, education, medicine, or some other field of research, what characterizes the use of audiovisual

recording for case studies is the provision of infinitely rich detail of transient events—records that can be analyzed, reanalyzed, and annotated by one or many researchers. Present digital technology puts audiovisual recording methodology in easy reach from the standpoints of raw data collection, access, and sharing. Yet, the exploitation of these data is in its infancy because having access to this vast amount of data is so new. Many coding schemes and systems are being developed for storage, analysis, and data sharing. In addition to the unprecedented magnitude of data, challenges in the use of audiovisual recording for case studies include the time consumption for data collection and subsequent coding and transcription, choice of coding standards, privacy and other ethical issues, reliance on collaboration, data backup systems, and questions of validity (the effect of camera or videographer on participants).

---

## AUTHENTICITY

---

Within philosophy the question of authenticity is essential to any notion of the “good life” and venerable as the Socratic argument: The unexamined life is not worth living. Authenticity, the quality of being authentic, is a central philosophical and ethical concept found in the works of Jean-Paul Sartre and others such as Lionel Trilling and Charles Taylor. Case study and qualitative research can be considered valid only if the collection, interpretation, and assessment of data are authentic. Within the social sciences some notion of authenticity is germane to the objectivity controversy.

### Conceptual Overview and Discussion

Sartre’s juxtaposition of subjectivity and objective reality underscores the feminist, postcolonial, and postmodern critique of objectivity. For Sartre, authenticity is the opposite of bad faith and refers to the alignment of subjective consciousness (i.e., *pour-soi*) with its objective reality (i.e., *en-soi*). One implication of this dualism and the problem of bad faith is that all knowledge is biased. This question has been taken up by the postpositivists (e.g., feminist, postmodern, postcolonial, queer theorists) in their critique of positivism.

The postpositivist argument is that from within the positivist paradigm, researchers (i.e., the subject) are required to study human phenomena (i.e., the object) objectively. Objectivity is possible only when researchers approach the object(s) of their research with impartiality and with dispassion so as to avoid contaminating it and thus to minimize and hopefully eliminate bias. This, the postpositivists argue, is impossible because objective reality and the subject are always in the process of becoming and can never be apprehended other than through preconceived and always partial frameworks or paradigms. Therefore, all research is contaminated by researcher subjectivity and what comes to be accepted as true is merely that which is accepted as such by tradition or authority.

Given the hierarchical basis of tradition and authority, all subjectivities and by extension all research serves some, usually dominant (e.g., male, modernism, imperialism, heterosexism) as opposed to other, often subordinate (e.g., female, Islamic or

Christian fundamentalists, indigenous peoples, homosexuals) interests. Further, the objectivity parameter is morally indefensible because it preempts and silences these alternative voices. If no one subjectivity can claim ultimate truth, then all subjectivities are equal; thus, the voices not only of the researcher but also those of the researched must be collected, analyzed, and interpreted. This leads to the criterion of reflexivity.

Finally, if no one voice can be privileged and all voices are biased, then truth is always conditional and can emerge only through mutual interrogation and consensus in situ. This leads researchers to adopt a participatory action-based approach. Among case study and qualitative researchers, the question of authenticity is an important concept that leads to the debate on validity and how to collect and assess trustworthy data as well as their interpretation.

Contemporary researchers have solved this dilemma in a number of interesting ways. Egon Guba and Yvonna Lincoln, for example, argue that the question of validity is by definition one of authenticity and have identified five criteria: fairness, ontological authenticity, educative authenticity, catalytic authenticity, and tactical authenticity. Fairness refers to the necessity that there should be a balance of voices such that all contributors to the research project are heard. Ontological and educative authenticity refer to the necessity of raising awareness among participants in and those affected by the research. Catalytic and tactical authenticities refer to the prompting by the research of interest-based action among research participants and the involvement of the researcher in educating them, if it is so desired, for political action, and the furthering of positive social change.

### Application

In facing the question of authenticity and mirroring the five criteria provided by Guba and Lincoln, Russell Bishop, based on a review of the existing relevant literature, has demonstrated how most research on the Maori peoples of Aotearoa/New Zealand has tended to serve and perpetuate colonial interests, denigrate Maori values and practices, simplify and misrepresent their knowledge, and thus create and perpetuate their subordination. In reaction to researcher colonization, the Maori have

become increasingly concerned about to whom researchers are accountable, who has control over the content and dissemination of research findings, as well as who will gain from it, and as a consequence are now demanding full participation within and control of all research pertaining to them.

To avoid these problems and to assess and ensure the authenticity of further research, the Maori concerns, which by extension would be those of all researched groups, particularly those holding subordinate status positions, are summarized by Bishop. They are: initiation (how does the research originate, by whom and for what purpose); benefits (who will gain from it); representation (are the findings trustworthy, and whose depictions of reality will be presented); legitimacy (are alternative or subordinate voices being heard or silenced); and accountability (who has control over the initiation, data collection, termination, and dissemination of the research). Bishop bases these criteria for research findings on a series of reports that have adopted a postcolonial approach.

He concludes that for researchers adopting a postcolonial framework there are two important requirements and consequences of the endorsement of authenticity. They are: (1) researcher reflexivity and the recognition of and integration of authentic Maori values, beliefs, and practices resulting in the creation of valuable new knowledge; and (2) the development of awareness that can point the way forward to fresh and positive social change.

### Critical Summary

The research agenda suggested by an adoption of the concept of authenticity in practical terms is without doubt beneficial; however, the logic and implications of the philosophical argument underpinning it have come under scrutiny. First, if researchers accept the doctrine of authenticity, then by definition they have accepted a viewpoint originating in the external world and are thus unauthentic. Second, if all persons act authentically and solely on the basis of their own self-interest, there is no overarching guarantee of group consensus or solidarity. Third, the concept of authenticity emanates from the essentialism of Enlightenment philosophy that posits a false distinction between subject and object/consciousness and the external world that is a logical contradiction

because subjects and their objects are inseparable and thus their separation is now recognized as artificial. In sum, while the idea of authenticity may have informed a very welcomed move to more open, innovative, multivocal, and participatory research agendas, the research field, as Guba and Lincoln outline, is presently a cacophony of paradigms—from positivism to postpositivism, and critical theory to constructivism—and their associated methodologies ranging from experimental and quantitative, modified experimental quantitative and qualitative multiplism, dialogic/dialectical, hermeneutical/dialectal to participatory action, shared experiential and autoethnographic. Multivocality is at times too raucous for the listening ear.

## AUTHENTICITY AND BAD FAITH

---

Authenticity and the related notion of bad faith are specific concepts and concerns found in the works of the French writer and philosopher Jean-Paul Sartre (1905–1980). These ideas can be applied to case study research as an approach to understanding situated individual freedom as well as an ethics of personal freedom of choice.

### Conceptual Overview and Discussion

Sartre was largely concerned with freedom, responsibility, and ethics, and he explored these themes through his plays, novels, and his best-known philosophic treatise, *Being and Nothingness: A Phenomenological Ontology*. Crucial to understanding Sartre's notion of how one is to act authentically (in Sartre's terms, this would be seen as acting in good faith) is understanding the fundamental nature of how we exist in the world. In his ontology, Sartre describes two main groups of things: those that are so-called *being-in-itself* things that do not possess freedom of choice (e.g., a rock) and *being-for-itself* things that do possess freedom and choice (i.e., human beings). Creatures of free choice commit bad faith when they act as though they do not possess this innate freedom. This is therefore seen as acting in a fundamentally inauthentic manner, based upon the denial of one's own innate ability and freedom to make choices.

According to Sartre, there are a variety of ways in which an individual may act in bad faith. These examples he places in some broad categories. For instance, simply denying our own freedom of choice is one way to act in bad faith. Beyond this simple denial of freedom, Sartre also details a number of social situations that represent nuanced ways in which we might act according to the wishes of other people, thereby effectively denying ourselves our innate freedom of choice. These social situations are broadly termed *being-for-others*. In essence, to deny either our own facticity (i.e., the given aspects of our situation, such as where we were born or our past choices) or our transcendence (our ability to choose to become something different from what we are) is to act in bad faith. If we privilege one aspect of our being-for-itself (facticity or transcendence) over the other aspect of our existence as creatures of choice, we act in an inauthentic manner. In Sartre's philosophy, to accept and to actively make decisions based upon the sometimes ambiguous interplay between these two characteristics of our existence is to act authentically and therefore in good faith.

### Application

There are a few notable examples of the specific application of authenticity and the ethics of good and bad faith in the broad range of case studies.

Perhaps unsurprisingly there is evidence of the use of the ideas surrounding freedom and authenticity contained in Sartre's own works. These works of philosophy, plays, and other artistic works are prime examples of the existentialist idea of "committed literature," which is in itself a type of case study.

One of Sartre's best-known cases for the examination of the bad faith trap found through being-for-others is found in *Being and Nothingness: A Phenomenological Ontology*. Sartre spent much of his time writing in cafés, so his use of the particular case of a waiter acting in bad faith is not surprising. Sartre describes how this particular waiter is playing at being what he thinks a waiter should be. The mannerisms, timing, and actions are all studied and practiced in such a way that the waiter is treating himself as though he is nothing more than a thing (in this case, a waiter in a café). This man is acting in the manner in which he knows others expect a waiter to act. He is acting as more of a waiter than any waiter could be. In doing so, the waiter is effectively denying his transcendence; by example, he is refuting his freedom to be other than a waiter. Thus, by treating himself as a being-in-itself thing (in this case as the very sort of waiter that is expected by others), he is acting without authenticity and in bad faith. Through describing this case, Sartre captures the sense of the ethical transgression found in the bad faith act of denying one's own freedom, particularly through accepting the constraints found when acting within limitations placed upon us by others.

The use of authenticity and bad faith in case studies goes beyond the examples and literature from philosophers such as Sartre. Svejnova examines the case of a famous Spanish filmmaker to uncover processes involved in authenticity-driven creative career choices. In this study, while not specifically citing Sartre's concepts of good and bad faith, the operationalization of the term *authenticity* clearly encompasses the balancing between facticity and transcendence so necessary for a Sartrean view of authentic being. In the context of a troubled-youth residential treatment program, Leveille offers an assessment of the problems and benefits of using a phenomenological approach to such treatment. Authenticity and the problems of balancing the requirement to both treat the residential program attendees as being authentic while simultaneously expecting councilors to act

authentically are explored. The author implicitly highlights the difficulty faced when one individual's freedom of choice is confronted by another individual's freedom of choice; the so-called *problem of the other*. This particular challenge is well described by Sartre as "the look" and is part of the profound difficulty in acting authentically, especially when we feel the limitations placed upon us by the conceptions of others.

Finally, there is some appropriation and use of Sartre's existentialism, more specifically discussions of good and bad faith, in the organizational analysis literature. Yue and Mills apply Sartre's existentialism to an examination of the process of organizing and identity construction within a team of mountaineers. Through combining the ontology of Sartre and the sensemaking epistemology of Weick, the authors explore what happens during the interruption of organizing processes. Using the tale of two climbers and their near tragedy in Peru as a case study, the authors illustrate how the freedom to choose one's own identity is essentially a survival trait evidenced during the collapse of an organizationally based identity. This freedom is seen as evidence of an ethical imperative to act in good faith, even in terms of how an individual creates his or her own identity. In this way, the facticity of an individual's situation is intertwined with the individual's quality of transcendence such that we are given an example of how authenticity may be played out in the most extreme situations.

### Critical Summary

Applying Sartre's concepts of authenticity and bad faith in case research offers a unique opportunity to use a particular concept of ethics to understand how individuals navigate their choices and the consequences of such. Acting authentically in this respect requires that individuals recognize the full range of their choices and make informed and active decisions. Through honoring both the facticity of their situation and at the same time their capacity to transcend, individuals may be seen as acting in good faith. Likewise, a denial of free will constitutes acting in bad faith. In case studies, this interplay may be examined in terms of a particular decision or patterns of decisions as well as implications for the self and others. Treating oneself as having no choice, or acting unthinkingly in accordance with others'

conceptions of us is inauthentic. Thus, Sartre's contention that to act ethically is to act authentically (in good faith) is an individual centered ethics; one not constrained by external standards or conventions. Indeed, to act unthinkingly in accordance with an external set of rules would fundamentally be an inauthentic act of bad faith because authenticity resides uniquely with each one of us. Essentially, individual responsibility remains at the heart of Sartre's concepts of freedom and likewise forms the core of any case analysis that makes use of the same.

## AUTHOR INTENTIONALITY

---

Author intentionality in case study research refers to the rationale, set(s) of reasons, or circumstances that have led to the conception, design, and implementation of a particular study. Simply put, what factors contributed to the author's interest and approach to a particular study?

## Conceptual Overview and Discussion

Author intentionality may be declared, implied, or inferred depending on what authors choose to reveal about themselves or their motivation that might provide added value to understanding aspects of the approach to problem conception and formulation.

In declared intentionality, the author openly professes orienting perspectives that underlie rationale, problem-posing, or methodology. A declaration such as “I teach learning disabled kids in a public school, am studying cognition, and want to learn more about the poor reading skills of young males” made as part of an introduction or in a biographical note gives the reader an inside track. Detectable in the declaration are the author’s profession, professional interests, and location of work as well as likely qualifications, educational background, and current academic status, in addition to the guiding practical assumption for the main question (i.e., poor reading).

Implied intentionality is less obvious than declared intentionality and follows implicit orientations that are consistent with guidance from a superordinate authority, such as discipline or department expectations might require. If an author is a member of a predominantly behaviorist academic environment, conducts research, and publishes articles in behaviorist journals that invoke principles and practices consistent with behaviorism, it may be assumed that the author is most likely a behaviorist and that the intentionality of her or his research leans in that direction.

Inferred intentionality involves a hermeneutic or interpretative reading of materials where little may be known of the author, such as might occur when referees provide blind reviews for journals or when new scholars encounter names unknown to them. Text in the context of declared or implied intentionality carries both message and messenger. Text without context, or message without messenger, can be judged by the reader only from her or his prior knowledge and on the merits of the text itself. Making the intentions for a particular choice of research topic or approach obvious does not imply any measure of quality or insight.

Author intentionality can be derived from an expressed or felt social or personal need, findings from a needs assessment, response to a funded call

for proposals, or simply heeding the call to publish or perish; all give rise to initiation of research and the engagement of authors. Author intentionality is a double-edged sword in that a champion is often required to bring needed research to the attention of the scholarly community and investigative fruition, but excessive advocacy can represent the same dilemma as experimenter bias in quantitative research in that confounds or alternative explanations of circumstances and findings may not receive the balanced treatment required for robust conclusions. Subjective-objectivity or objective-subjectivity are more than semantic twists and represent a state that many researchers strive for and never quite reach. By virtue of conceiving and undertaking a research project, the attention and subsequent investment of time, energy, and other expenditures create a vested interest on the part of the researcher.

Author intentionality may arise implicitly from tacit assumptions embedded in the personal history of the researcher. Influences from demographic traits such as race, class, gender, geography, political stance, or religious conviction may find encouragement or challenge when reconstructed through the rigors of formal graduate study. If a researcher with a given set of personal attributes or characteristics undertakes a study of a group sharing those characteristics, then a (dis)advantage of insider knowledge may occur. Insider knowledge can be advantageous to the extent that it allows the researcher special insights into issues that those under study experience.

By way of example, teachers who study teaching can be expected to have a range of insider knowledge that encompasses subtleties of teaching not available to a researcher from another field, such as an epidemiologist. However, in teaching, subvariations from (dis)ability or demographics may constrain appreciation of specific perspectives. A teacher of English carrying out research may be aware of, but lack specific knowledge of, dyslexia and its many subtypes, or of critical feminist views of text, subtext, and context that affect understanding the cross-disciplinary fullness of an issue. Author intentionality may apply here as well if the intention of the research is to understand, learn, and discover as well as produce a specific nugget of knowledge about an event.

The disadvantage of insider knowledge includes such situations as perceptual blindness

or hypersensitivity because of situation or event familiarity in which basic assumptions are actually unchallenged or taken-for-granted understandings or principles arising from personal history or uncritically accepted professional experience. For example, in an era of school change, many new policies are put into practice based on research that deals with effective implementation but without initial research determining the actual need for change and the level of expected agreement and cooperation among those affected. Author intentionality as a negative effect may be neutralized to the extent that the author is willing to step aside from personal history and taken-for-granted assumptions and adopt an open-minded inquiring stance.

### Application

Max Weber and others have written about and discussed the ideas underlying a *verstehen* approach in which the researcher first simply seeks to understand the circumstances of the situation in which the study will be located and carried out. Such *research by wandering around* assists the development of intentionality in ways less affected by predisposition, as the basis for inquiry dependent on perspective(s) brought by the researcher are tempered by deepened understanding and consultation with those under study. Judicious application of “Well, so what?” and “Who benefits?” questions applied to study descriptions can identify and expose interests that might affect question or hypothesis development and choice of methodology and methods that can affect outcome. Bodies of research do exist that stand in opposition to each other, as might be found in studies that support the harm or harmlessness of substances such as tobacco, alcohol, or marijuana, where vested interests may guide author intentionality.

A clear contrast of the types of intentionality is most visible in the works of such writers as Richard Dawkins, whose views of evolution and God exemplify declared intentionality. “Intelligent Design: The Scientific Alternative to Evolution” exemplifies implied intentionality and is produced by writers whose works and words consistently support a creationist or intelligent genre. An example of inferred intentionality can be found in Rushton’s *Race, Evolution, and Behavior*, in which

the author infers individual differences based on race alone.

Author intentionality may also be a necessary condition of discovery in some types of investigative inquiry. Beyond the ever-elusive *causal relationships* between and among researchable events, the idea of *logical relationships* can be considered. Fostered by a Sherlock Holmes-like disposition, developed through a *verstehen* approach, felt connections and entertainment of logical relationships between and among events or individuals may assist in the production of issues and questions to be addressed through more structured approaches and contribute to an emergent author intentionality. Observation of increased literacy among young people that focuses on *how* the capacity to read is best attained (e.g., phonics *vs.* whole language) will likely experience skewed results unless taking into account the era of J. K. Rowling’s Harry Potter books and the subsequent spike in reading interest that also leads to addressing the *what* of reading.

Ex post facto (after the fact) research as considered in quantitative applications draws on cold data used to describe or infer occurrences or patterns in time after an event has occurred. A similar approach is used to conduct biographical or historical research where the author’s intention may relate to discovering and illustrating evidence that confirms, conforms to, or contradicts an existing arrangement or interpretation of events or artifacts. History depends on the historian and accounts for variations in rationale and fact interpretation such as might occur in British, American, or Native accounts of events leading up to war and a declaration of independence in the United States. Similarly, the lives and experiences of individuals, schools, communities, and nations may be used to render accounts consistent with and supportive of author intentionality, whatever that may be. Any consideration of historical information must attend to at least two contexts: history as seen in the present, and history as viewed through intent of the author.

### Critical Summary

Author intentionality may be used to construct or buttress favored positions, points, or outcomes of research. When such strategies are used, authors are advised to clearly identify affiliations or preferences that cast arguments in specific directions.

Otherwise, readers need to use constant vigilance to detect underlying leanings that may distort full understanding or appreciation of the materials presented.

## AUTOBIOGRAPHY

---

In autobiographical case studies, the individual who is the subject of the study writes his or her own life's account. These accounts are in narrative form and include diaries and journals used to record the events of one's life and are generally written with consideration of a future readership. More recently, feminist autobiographical approaches have expanded the literary tradition of autobiography to include not just written but also

spoken and visual genres such as interviews and family photographs. In expanding and revolutionizing what constitutes autobiography, social practices that are a part of our everyday life and mark the links between the personal and the political have been reconstituted as autobiography.

### Conceptual Overview and Discussion

The canon of Western autobiography, Phil Cohen argues, has been historically male centered and has featured the life writings of both the elite and self-made men. An emancipatory vision and practice outside these confines advanced by feminist scholars, particularly over the past 30 years, has taken place alongside postcolonial criticism that has contributed, as Carolynn Steedman notes, to a shift away from a gaze focused solely on the European subject toward that of subaltern and marginalized subjects, such as the working class, women, and people across national and ethnic contexts. Similarly, approaches to autobiography have undergone scrutiny and critique. They have moved from a single emphasis on written literary texts to a proliferation of alternative forms of self-narration that include written texts, oral narratives (the spoken), fictional accounts, curricula vitae (CVs), and the visual.

Tess Cosslett, Celia Lury, and Penny Summerfield, the editors of the milestone book *Feminism and Autobiography: Texts, Theories, Methods*, feature theoretical advances and research methods that include autobiographical case studies. They identify the development of feminist autobiography in three areas: genre, intersubjectivity, and memory.

*Genre.* Feminist critique of autobiography as a literary genre whose beginnings arise from the accounts of elite white males is scrutinized for its exclusionary practices. The notion of the autobiographer as a unified, transcendent white subject is questioned. Differences that underscore sexuality, nationality, age, class, culture, and race are interwoven in feminist autobiographical investigations.

*Intersubjectivity.* This term refers to the examination of the relationship between personal narratives and the public realm. This includes the

examination of how experience is both narratively and dialogically organized. Cosslett, Lury, and Summerfield argue that knowledge of these relationships is central for a nuanced understanding regarding the process of composition through which a narrative is produced. Feminists use interiority because women's narratives are often excluded from the public realm. Intersubjectivity insists that that self cannot be analyzed as an isolated subjecthood, but rather, it must be understood in relationship with others—through which the self is constituted.

*Memory.* Memory involves recovery of the past. Further, Cosslett, Lury, and Summerfield highlight the importance of the past in relation to a projection of the future. Memories are taken up within the personal and collective realms and are often conveyed through partial, shifting, and contested nuances. Further, memory can carry political connotations in terms of what is remembered (both the silences and gaps) as well as what is forgotten, as Luisa Passerini suggests. Of particular importance is the notion that memory is not just individual but can also be shared, or does not necessarily have a single owner. For example, shared memory is exemplified through the media or through shared rituals.

### Application

The work of prominent feminist scholars who dedicate their research to autobiography, such as Liz Stanley, Gwendolyn Etter-Lewis, and others, are featured in Cosslett, Lury, and Summerfield. Their works provide examples of the three identified areas of knowledge in the field of feminist autobiography, some of which are briefly highlighted for their clarity in application:

*Genre/Liz Stanley.* Stanley's discussion of the epistemological significance of auto/biography disrupts the perception of autobiography as a literary text. She argues that auto/biography should not be confined to written texts but is a part of everyday practices. The focus on epistemological matters provides an analytical tool for examining the relationship between the individual and social structures. For example, Stanley discusses the everyday practice of constructing a CV for a job or for promotion, and the

act of describing oneself to other people as auto/biographical.

*Intersubjectivity and Memory/Gwendolyn Etter-Lewis.* Etter-Lewis provides an in-depth autobiographical case study of attorney Evva K. Heath (between the years 1897 and 1909). She examines over 101 letters written by Heath to her family (mostly her mother) as a means to build a larger autobiographical narrative. Heath (1880–1909) was a Howard University School of Law graduate in 1904 and was among a small number of African American female attorneys who also concentrated on women's legal rights. Through Heath's case study, Etter-Lewis provides an example of how the "self" subjecthood (or interiority) can be understood only in relationship with others and moreover within exteriority (the social structure). Etter-Lewis provides an analysis of Heath's "multiple selves" as constantly evolving in relation to external issues.

Consideration of Heath's reader/audience (mostly her mother) was also important to Etter-Lewis in order to critically examine the letters with an eye to interrogate the silences, both what was unsaid and what was constituted through social political contexts. Heath's everyday accounts censored life's sorrows and disappointments. These silences reflect the social political contexts in which her life's writing was taking place and were an outcome of Heath's race and gender within her professional class.

### Critical Summary

Cosslett, Lury, and Summerfield argue that the three identified areas reflect the interconnected frameworks currently under debate in feminist autobiographical studies. As such, both the conceptual framework and the application of these approaches are of central importance to highlight in a discussion concerned with autobiography as case study, particularly as they relate to developments and new trends in the field.

---

## AUTOETHNOGRAPHY

---

Autoethnography is a form or method of research that involves self-observation and reflexive investigation in the context of ethnographic field work and writing. The term has a double sense, referring either to the reflexive consideration of a group to which one belongs as a native, member, or participant (*ethnography of one's own group*) or to the reflexive accounting of the narrator's subjective experience and subjectivity (*autobiographical writing that has ethnographic interest*). This distinction can be blurred in some research traditions. Autoethnography is sometimes made synonymous with self-ethnography, reflexive ethnography, or performance ethnography, and can be associated with narrative inquiry and autobiography.

## Conceptual Overview and Discussion

The emergence of autoethnography as method, text, or concept was described by Carolyn S. Ellis and Arthur P. Bochner, and by Deborah E. Reed-Danahay as a manifestation of a recent reflexive turn in ethnography. Paul Atkinson, Amanda Coffey, and Sara Delamont argued that a diversity of methods and points of view have characterized ethnography since its outset, and the exclusive focus of this turn on methodological innovation, change, and discontinuity gives a misleading account of the field. Nevertheless, anthropology has recently shown a widespread and renewed interest in personal narrative, life history, and autobiography as a result of changing conceptions of self-identity and relations between self and society.

Autoethnography broadly operationalizes three different conceptions of self: *self as representative subject* (as a member of a community or group), *self as autonomous subject* (as itself the object of inquiry, depicted in "tales of the self"), and *other as autonomous self* (the other as both object and subject of inquiry, speaking with his or her own voice). It displays three main intersecting qualitative research traditions: analytic, subjectivist experiential, and poststructuralist/postmodern.

*Analytic autoethnography* is a subgenre of analytic ethnography as practiced from realist or symbolic interactionist traditions. Here a researcher is personally engaged in a social group, setting, or culture as a full member and active participant but retains a distinct and highly visible identity as a self-aware scholar and social actor within the ethnographic text. Analytic autoethnography differs from analytical ethnography by its increased interrogation of the relationships between self and others and a developed awareness of reciprocal influences between ethnographers, their settings, and informants. Researchers' own feelings and experiences are included in the ethnographic narrative, made visible and regarded as important data for understanding the social world observed, yielding both self- and social knowledge.

Systematic, self-conscious introspection enables the disciplined analysis of personal resonance and the effects of the researchers' connection with the research situation on their actions and interpretations, in dialogue with the representations of others. Researchers are in a paradoxical position in

the field: simultaneously insiders of the studied community and outsiders, members of another (academic) community, representing the “ultimate” participant in this dual role. Analytic autoethnography thereby reaffirms the distinctions between researchers and informants, observers and observed, or self and culturally different other prevalent in classical ethnography. It is also committed to an analytic agenda: Developing theoretical understanding of broader social phenomena, grounded in self-experience, analytic autoethnography remains framed by empirical data and aims to generalize its insights to a wider field of social relations than the data alone contain.

*Subjectivist experiential* autoethnographic writing aims to account for the subjective density of ethnographic field work, often in an *expressive*, emotional, and existential way. Concrete action, emotion, embodiment, self-consciousness, and introspection shape interpretive tales of the self where the narrators’ subjective experience is the central focus of the ethnography. These tales are ideographic case studies or life stories narrating the subjective meanings and human texture of lived experience, usually as first-person narratives by a common or ordinary member of a group or community. Subjective experiential autoethnography investigates subjectivity as a distinct phenomenon in all its emotional, cognitive, and behavioral density.

Personal stories are not a means to an end, as in the analytic tradition, but singular expressions of human life that fill and shape the text. Here the connection of the autobiographical and personal to the cultural and social through thick description has no explicit analytic commitment to generalization, though revealing situated cultural influences and broader social relevance. Subjectivist experiential autoethnography often conveys a specific standpoint or voice accounting for emotional and embodied experience of illness or discrimination, as in healthcare and feminist research. It is often used critically as a political means of expressing the repressed voices of minorities and communities.

*Postmodern/poststructuralist* autoethnography is a blurred genre of methodological creative practices, texts, and autobiographical performances that turn inward and are *waiting* to be staged. These contribute to remaking self and identity as a *site* for the negotiation of social, cultural, and political dialogue, often in a carnivalesque form.

Autoethnography is here mostly *evocative* rather than *expressive*, and its relevance is accomplished through a balancing act: Aesthetic concerns are balanced with the sharing of experience, the fragmenting effects of dialogues based on identity, and the need to connect local action to larger social and even global contexts, spaces, and locations. Social and cultural artifacts can be used as forms of autoethnography as they provide a form of self-reference for the members of a particular region or community. Traditional ethnography sees its task as the description, inscription, and interpretation of culture, but from a postmodern perspective the professional ethnographer becomes redundant because everyday practices are increasingly pervaded by impulses for self-documentation and the reproduction of images of the self. The radical dissolution of the ethnographic “I” and eye blurs distinctions between ethnographic representations of others (ethnography) and those others’ self-representations (autoethnography).

### Application

Autoethnography can take varied forms and genres. In anthropology, it is at the intersection of three genres of writing: (1) *native anthropology* (“people who were formerly the subjects of ethnography become the authors of studies of their own group”); (2) *ethnic autobiography* (“personal narratives written by members of ethnic minority groups”); and (3) *autobiographical ethnography* (where “anthropologists interject personal experience into ethnographic writing”) (Reed-Danahay, 1997, p. 2).

In *native* or *insider anthropology*, autoethnography is carried out in the social context that produced it. Its emphasis is not on life story but on the ethnography of one’s culture, as with analytic autoethnography. Confessional tales or partial autobiographical accounts have also long been used in analytic ethnographic field work to supplement ethnographic narration and provide the readers with details that unveil how field work was concretely performed, often presented separately from the main ethnographic narrative. Autobiographical vignettes can also enhance the subjectivity and liveliness of ethnographic discourse.

*Autobiographical ethnography*, including *ethnic* or *indigenous autobiography*, presents native

life stories having ethnographic interest as life trajectories, and identities are set in their social, cultural, and historical contexts. Using different written genres and methods, ethnography and autobiography are blended into new hybrids: witness narratives in cases of social violence and repression; private folk ethnography in households and specific collective settings; and testimonies of daily life in captivity, total institutions, armed conflicts, or self-reflection on symbolic violence.

Narrative inquiry can provoke identification, feelings, emotions, and dialogue. The development of experiential and postmodern autoethnography has expanded the range of cultural artifacts and textual projects used to document subjective and creative flows of human life. It also blurs boundaries between insider/outsider, subject/object, and ethnographic versus literary genres. Films, diaries, calendars, or children's fiction are now used creatively in addition to autobiography to explore subjectivity and lived experience. Polyvocal texts offer space for expression and evocation of a plurality of voices while responsive reading, reader's theater, or conversations can incorporate direct dialogue. Performance autoethnography engages with creative nonfiction poems, short stories, memoirs, comedy or satire, conversations, and dances as fields of inquiry.

### Critical Summary

Early criticism of autobiographical methods in anthropology questioned their validity on grounds of being unrepresentative and lacking objectivity. Recent critiques of evocative and emotional genres of autoethnography have mostly emphasized their lack of ethnographic relevance as a result of being too personal. The elevation of autobiography in personal accounts to the status of ethnographic enhancement, on the grounds of its evocative power or experiential value, has been criticized by analytic proponents for being biased, navel-gazing, self-absorbed, or emotionally incontinent, and for

hijacking traditional ethnographic purposes and scholarly contributions. The proliferation of methodological creativity in ethnographic writing has also been presented as a self-referential sphere of discourse disconnected from practice.

Nevertheless, such critiques should be relocated in a broader reflection on and discussion of the scope, purposes, and forms of ethnographic work itself. Evocative and emotional autoethnography promotes the ethnographic project as a relational commitment to studying the ordinary practices of human life, which involves engaged self-participation, makes sense in the context of lived experience, and contributes to social criticism. Analytical autoethnography finds it necessary to look outward at distinct others in order to generate meaningful social analysis.

## BASE AND SUPERSTRUCTURE

---

One of the main tenets of Marx's historical materialism is that societies consist of two main parts: the economic base and the political-cultural superstructure. The *base* is a society's mode of production—its economy and its social classes; the *superstructure* is everything else, including politics, family, law, and religion. The building metaphor of base and superstructure is used to convey the notion that the visible parts of the building, namely politics and culture, are constructed on a more fundamental and important economic foundation. According to the base-superstructure idea, all case study research should aim to identify the economic and class preconditions of whatever phenomenon is being studied.

### Conceptual Overview and Discussion

The origins of the idea were partly philosophical and partly political. Philosophically, Marx was hostile to idealism and he affirmed materialism. Politically, Marx dismissed rival forms of socialist thought on the grounds that the road to communism required not a moral conversion in the mind (the ideological superstructure); nor would political change suffice (the political superstructure); instead a socioeconomic revolution in the material conditions of life and in class relations (the base) was needed.

Marx used the term itself when summarizing the materialist conception of history in his "Preface" to

*A Contribution to the Critique of Political Economy* in 1859. He describes the mode of production as the real foundation upon which arises a legal and political superstructure as well as forms of social consciousness. Social, political, and intellectual life are conditioned by the mode of production.

The metaphor contains three main ideas. First, there is the assumption that society is like a building. Part of the assumption is that society is built or constructed, as opposed to having evolved or grown. Part also is that, like a building, a society is composed of levels such as a basement and upper stories. Yet the likening of societies to buildings did not go unquestioned by critics. Critics charged that societies are not akin to buildings; they are not constructed out of raw materials but instead are composed of specifically human activities; they are far more complex than buildings; they cannot easily be torn down and rebuilt to new plans.

Second, there is the implication that what happens in the economic realm is hidden or taken for granted as is a building's underground substructure. The base-superstructure image is in this way similar to the image of a passenger ship in which the privileged in the upper salons are insulated from the harsh conditions of the stokers in the engine rooms.

Third, there is the thesis that the economic forces and relations of production are more important, influential, and fundamental than any other aspect of life because they are the bases or preconditions of every other social activity. Marxism split into two tendencies on this point. One tendency, sometimes referred to as "vulgar" or "determinist" Marxism,

held that the forces of production and class relations directly control the rest of society. All else is an epiphenomenon. The other tendency, associated primarily with Antonio Gramsci, granted relative autonomy to politics and culture while endorsing economic determination in the final instance.

### Application

Among the most important areas of application of the base–superstructure idea have been studies of (a) the preconditions of social institutions; (b) the theory of history; and (c) the preconditions of communism.

#### *Preconditions of Social Institutions*

One realm of application concerns the bases of social institutions. Some of the most notable ideas from the history of Marxist thought are in essence applications of the base–superstructure notion. These include the claims that ancient Greek democracy rested upon slavery; that late 19th-century European imperialism arose from a new stage of capitalism; that World War I was caused by economic imperialism; that the institution of the free market has as its precondition class division; or that political democracy is a sham in a class-divided world. But critics argue that social institutions also have other noneconomic preconditions. Social institutions also depend upon cultural supports or military security. Critics also state that notwithstanding their economic preconditions, social institutions also have emergent properties of their own.

In the Marxian view, the preconditions of revolutions are to be found in the base: economic crisis and sharpened class struggle. But Theda Skocpol's case studies of the French, Chinese, and Russian revolutions challenged this notion. The main condition of revolution arose as much in the superstructure as in the base: State breakdown due to military defeat, fiscal crisis, and divisions among the elite were the main sources of those revolutions.

#### *Theory of History*

A second realm of application is the theory of history. Although the base–superstructure metaphor gives a static image of a building at rest, Marx's materialism was explicitly historical: Marx called

his approach the materialism conception of history, later shortened to historical materialism. It is a dynamic theory of history in motion. According to Marx's theory of history, the basic entities of history are not states or civilizations, but modes of production. History is the history of successive modes of production from antiquity through feudalism to capitalism to future communism. The sources of historical change arise from the mode of production: Change comes partly from the effects of advancing forces of production and partly from the struggle between classes. The overall direction of history is a progression from inferior to improved modes of production culminating in the best possible mode: communism.

This is to be contrasted with other ideas of the shape of history. One idea is that history comprises three economic epochs: the foraging (or hunting and gathering) age, the agrarian age, and the modern industrial age. (This approach differs from Marxism in disputing the importance of social classes.) Another idea is that cultures, civilizations, religious movements, or ideologies form history's main entities and sources of change. A third is the view that warfare is the main influence on history. A fourth is that the main entities of history are political and geopolitical (regimes, states, systems of states, and empires) while the main source of change in history is the struggle for political power.

In contrast to all the above, a further idea of history is multidimensional. This is the kind of approach associated with Max Weber as opposed to Karl Marx. Multidimensional approaches come in various forms. One would regard each type of human activity as equally influential in shaping history. An alternative would regard the main influences as varying between different eras: in some periods, economic primacy; in other periods, military primacy; in others, cultural.

#### *Preconditions of Communism*

Marxism claimed to be able not only to *interpret* the world but also to *change* the world by revealing the preconditions for achieving communism. This third realm of application has led to intense controversy.

The base–superstructure idea aims to offer a guide to how to achieve communism. It advises those who would change history to act not in

political institutions or in terms of ideas, but instead at the level of economic development and at class relations that together form the prevailing mode of production. The key to achieving communism is to transform the base by advancing the forces of production and abolishing classes through the victory of the working class. Both were to be achieved through planning and state control of the economy. For some time it seemed to many that Marxism had successfully identified the precondition of communism. Communist parties across the world were devoted to implementing the formula of transforming the economic base.

Critics make several points. One criticism is that the base–superstructure idea in Marxist theory contributed to the disastrous lack of democracy in communist practice. Marxist theory was in principle in favor of democracy. But, at the same time, Marxist theory relegated democracy to an epiphenomenal or superficial position within the superstructure. The criticism is that the base–superstructure image, by demoting democracy to a secondary position in its theoretical picture of a society, encouraged communist movements to regard democracy as unimportant. Another criticism is that transforming the base is not the precondition of achieving communism. Critics of Marxism charge that there are no such preconditions because achieving communism is a utopian fantasy. Ideas such as the base–superstructure notion that purport to reveal the preconditions of communism are therefore fatally flawed.

### Critical Summary

The idea that case study research should consider how economic circumstances, among other things, influence the phenomena under study is uncontroversial. But the idea that case study research should primarily aim to reveal the economic and class preconditions of its subject matter is deeply contested.

## BAYESIAN INFERENCE AND BOOLEAN LOGIC

---

Bayesian inference and Boolean logic are logical–mathematical approaches to inquiry that contribute to the construction of sound case studies. That is, they constitute applications of formal logic and statistical reasoning that may enhance case study research.

### Conceptual Overview of Bayesian Inference

Bayesian inference is an approach to the interpretation of statistical evidence inspired by the contributions of 18th-century statistical theorist Thomas Bayes. It is based on the concept of conditional probability, in which one recalculates the likelihood of an event based on new evidence, as codified in Bayes’s theorem. Bayesian inference introduces the concept of the “degree of belief,” emerging through an iterative process, in which successive exercises generate new understandings of reality. It is to be distinguished from traditional hypothesis testing with null hypotheses, Type I and Type II errors, confidence intervals, and critical values.

Bayesian inference produces a conception of the “state of knowledge” at a given moment. The researcher posits prior probabilities, perhaps based on his or her own intuition or on a broader consensus, and these are taken into account as an experiment or study produces *posterior probabilities*. Posterior probabilities represent revised assessments as determined by subsequent analysis.

Following the Bayesian theorem, posterior probabilities can be calculated according to the following formula:

$$P(H|E) = P(E|H)P(H)/P(E).$$

$P(H|E)$  is the posterior probability that Hypothesis  $H$  is true given that Evidence  $E$  has emerged.  $P(H)$  is the prior probability that  $H$  is true, as assessed before the arrival of Evidence  $E$ .  $P(E|H)$  is the probability Evidence  $E$  would arise given the truth of Hypothesis  $H$ .  $P(E)$  is the probability of  $E$  occurring regardless of the correct hypothesis.

Many critics regard Bayesian analysis as necessarily subjectivist, in that inquiry begins with the researcher's initial judgments (which may be characterized as "biased") and continues to be guided by the researcher's belief. On the other hand, subsequent iterations of analysis may suppress initial biases and introduce grounds for broad credibility. A minority of critics find Bayesian inference consistent with objectivity and Aristotelian logic, and interest in Bayesian approaches is increasing.

Bayesian inference is quite useful in combination with case study analysis. That is, the researcher may consider statistical evidence, make an inference along with an assessment of degree of belief, and then incorporate case analysis, which either reinforces or weakens earlier judgments. Bayesian analysis provides a justification for the integration of multiple methodologies in a single project.

Consider, for example, the effective use of polling in political research. The point estimate of support for candidate or party is of limited value in and of itself. A Bayesian approach builds an analysis conditioned by the estimate but refined through the analysis of rally size, polling place lines, and other factors. Projections of United States presidential elections necessarily combine state-level predictions and the consideration of electoral college scenarios ensuing from them.

### Conceptual Overview of Boolean Logic

Boolean logic is a system for performing logical operations in the analysis of sets, or groups, of numbers, objects, or events. It is the foundation of database search engines and the basis of computer information processing. It incorporates the logical operators AND and OR, which are equivalent to union and intersection in symbolic logic. These operators render large databases more manageable; for example, multiple search terms can identify relevant articles from an extensive library of journals.

Boolean logic can be applied in the analysis of organizational states construed as sets. One can

explore relationships among the underlying factors determining membership in sets, even if these factors are qualitative in nature. Venn diagrams provide graphic representations of these relationships, revealing intersections and complementarity, and truth tables list propositions about the relationships. Boolean logic may be particularly helpful in considering organizational processes characterized by equifinality, where multiple paths lead to the same end states.

Boolean logic might be applied in comparative studies of organizational performance, whether with regard to financial performance, social responsibility, or some other dimension. Case studies provide the raw information. The objective would be to illuminate the various paths through which organizational configurations result in the performance in question. Sets are constructed grouping enterprises that qualify on each of the relevant variables. Venn diagrams illustrate relations among the sets. Logical statements utilizing the Boolean operators define potential configurations, and these may be arranged as a truth table to distinguish paths to favorable and unfavorable outcomes. Recent studies of high-performance work organizations identify diverse bundles of human resource practices that are associated with improved quality and implicitly employ a set-theoretic approach.

### Critical Summary

Both Bayesian and Boolean logic provide means to construct rigorous and powerful analyses from the building blocks of case study. However, some critics continue to argue that Bayesian approaches are inherently arbitrary and subjective. Boolean logic remains somewhat obscure in social science research despite its particular value in the consideration of case studies.

## BEFORE-AND-AFTER CASE STUDY DESIGN

---

A before-and-after case study describes a single example of a phenomenon or experience involving individual, group, institutional, or social responses before and after an event of interest. Completion of a before-and-after case study could do some or all of the following: deepen the understanding of aspects of the *before* period of the case study; identify the pivotal event(s); and clarify the changes in the *after* period. Outcomes of such a study could include theories on the impacts of the events, related change efforts, or future interventions.

### Conceptual Overview and Discussion

Case study research has been useful in answering *how* and *why* questions from real-life contexts, often in professional practice areas such as education, human services, leadership development, and management. The multiple data sources of the case study from the first period of the research may stand alone, or become the basis for learning about the impact of some pivotal events, and involve a second period of data collection. This second phase of data collection, after some event(s) of interest, is the marker of a before-and-after case study. Before-and-after case studies provide the opportunity to (a) analyze complex case data, (b) see pivotal events or relationships among the factors affecting the dynamics under study, and (c) gather further data to examine those affects or changes.

The protocol for case study research design suggested by Robert Yin includes (a) an overview of case study and the research questions, topics, and issues; (b) nomination screening and data collection procedures in the field; (c) schedule and deadlines

for case studies from preparation, through site visits, follow-up, analysis, report preparation, and site review of report draft; (d) update of protocol related to literature, hypothetical logic model update (if used), topics, and data collection; and (e) case study report format. In addition, a before-and-after case study includes the pivotal event, and the components of design in the second part of the case. These second section components may include chronological analysis, continuity or changing of evidence sources, prediction of causal factors and subsequent verification, alternative explanations, new theoretical propositions, new descriptions following the pivotal event, and changing rival explanations.

Norman Denzin and Yvonna Lincoln suggest “conceptual responsibilities” in research design that include (a) the case boundaries around the object of study; (b) research question emphasis on which themes, issues, and phenomenon; (c) developing the issues through the patterns seen in the data; (d) triangulating data for important observations and interpretations; (e) including alternative interpretations; and (f) developing generalizations. Case studies may be strengthened by research designs with multiple sources of evidence such as interviews, real objects, archived documentation, recorded observations, and participant observations. Current technologies add many possible tools and sources. A before-and-after case study design would include the differences in data collection sources in the before time period, during the pivotal event, and in the after-event time period. Similarly, the analysis strategy and analytic techniques used need to be described for each time period. For example, an initial theoretical proposition with rival explanations included may have time series analysis added to the second part of the case study after the pivotal event. The purpose of the chronology could be to increase the relationships between patterns in the initial part of the case study and variables introduced by the pivotal event. The use of chronologies and pattern matching could assist with comparisons when research designs were different in the before and the after case descriptions.

One case study or multiple case studies can be included in a before-and-after strategy. Different protocol variables would be described. For example, validity and reliability concepts in data collection and analysis of case studies require different

tactics in different research designs. The traditional concepts of validity (internal, external, and construct concept measurement), and reliability (degree to which the study could be replicated) are conceptually important in study design. For example, Yin suggests theory in single case studies, and replication logic in multiple case studies to test external validity (or generalizability parameters). A conceptual alternative to validity and reliability appears in Thomas Schwandt's describing authenticity or trustworthiness criteria developed by Yvonna Lincoln and Egon Guba for qualitative studies. Included in this alternative criteria are ontological authenticity (enhancement of participants' constructions), fairness (balanced representation of respondents' constructions), educative authenticity (shared understandings of others' constructions), and catalytic authenticity (stimulation to action).

In the academic context, the before-and-after case study has a direct connection with qualitative and quantitative methodologies. Case study methodology choices vary with the questions and purpose of the study. Common elements would be development of research questions; method for choosing participants; informed consent; description of the parameters of the study, including ethical considerations, phenomenon, and context; data collection; data analysis; and a case study report.

### Application

An example of choosing methodology in one study on effective cross-cultural teachers' multicultural frameworks was the use of James Spradley's 12-step ethnographic interview sequence. The interview sequence provided direction in steps to identify participants; ask descriptive, structural, and componential questions; analyze the interviews in domain, taxonomic, and cultural aspects; and write the narrative. Spradley's ethnographic methodology corresponded with questions of the study: (a) what are the backgrounds of effective cross-cultural teachers? (b) What are the teaching frameworks of effective multicultural teachers? (c) Can teachers describe their cultural teaching frameworks? The initial participant was both an exceptionally successful teacher recommended by her principal, student teachers, parents, and university partners, and also very articulate on all three questions. In this research the data complexity *before*

led to consideration of further interviews. The impacts of a *pivotal event* in education (implementation of the No Child Left Behind, or NCLB, legislation) had dramatically impacted U.S. teachers' views on classroom work. Public Law 107-110 (NCLB) was proposed by then-President George W. Bush, and signed into law on January 8, 2002. Main provisions of the law, according to the California Department of Education, include standardized testing to measure "adequate yearly progress," complex regulations for "highly qualified teachers," and mandated consequences for underperforming schools. The willingness of the case study teacher to participate in further interviews led to an *after* period of data collection in 2006.

The *before* of the case studies was teacher frameworks prior to the legislation in 2001, the legislation and policies and practices from the law were the *pivotal events*, and the *after* was teacher frameworks in 2006—after 5 years of NCLB implementation in schools. In the example described, detailed ethnographic methodology was used to develop the *before* part of the case study. Six years later, the methodology chosen for the *after* part of the study was institutional ethnographic tools, as it was institutional dynamics that had most strongly impacted the experiences of the teachers in 2006. The choices of which methodologies to use (after the case study form or strategy for data collection and analysis is decided) depend on the research questions and purpose. In the cross-cultural teacher example, a culturally descriptive and specific method was needed for the first period of data collection in three specific areas related to acculturation (teacher background) and a cultural practice (teaching). Six years later, an institutionally responsive inquiry method was needed to describe the institutional changes and their impact on teachers' experiences.

The researcher had not imagined or planned the pivotal events (federal NCLB legislation) that impacted every school in the United States. However, having studied a case of an exceptional cross-cultural teacher done in 1999–2001, the idea of looking at the impact of the NCLB legislation with an experienced and articulate teacher, already on record, was a chance to document what many teachers in the school districts around the researcher were discussing in parking lots and over coffee. The before-and-after case study presentation provided a

way to impact a teacher education program dealing with those changes. In other examples the events of interest may be historic, concurrent, or a part of the study.

Methodologies after the data collection choice for a case study is made vary from the detailed structure of multiple stage taxonomies in the data collection and analysis of Spradley's classic ethnographic interview sequence, to less structured methods; for example, using coding categories in a straightforward reporting of evidence. Yin lists evidence sources for case studies as documentation, archival records, interviews, direct observation, participant observation, and physical artifacts. Once the data from these sources are analyzed, theory building may result—and include all three periods, or focus on the before period, the pivotal events, or the after period. For example, in the teacher multicultural framework study, all three periods were included and resulted in a picture of the impact of NCLB on one very effective teacher who was taking steps to leave the profession 6 years after the before part of the study when she was fully engaged in complex cross-cultural learning strategies. A theory of dominant culture backlash to multicultural education successes was included in a presentation to a School of Education faculty and precipitated development of a doctoral program for leadership in this area. Decision makers may use before-and-after cases to discover the impacts of pivotal events, to increase successful interventions, to formulate theory to test in practice, and so on.

### Critical Summary

Before-and-after case studies are particularly useful for understanding specific contexts where the how and why of behavior are important, the context impacts the behavior, and there are pivotal events impacting people. The pivotal events may be theorized, part of historic records, an institutional or social dynamic, planned or unplanned. Before-and-after case studies can also direct research into new avenues of study on old issues. One example of this redirection was the resiliency case study research of the 1990s that focused on the factors enabling some students to be successful in circumstances where other students were leaving school and encountering multiple developmental challenges. The cases describing factors in

student success assisted educators in building in more of those factors for students in their high schools. Numerical data may be clear, as in the case of Los Angeles high school dropout rates, but the many factors involved in the how and why of dropping out were not clear. Both before and after graduation there were pivotal events impacting whether the cases (students) left or stayed in high school. Before-and-after dropping out studies helped identify those events.

A limitation involved in before-and-after case studies is the additional time in extending data collection with the *after* period. The ethical considerations can also be daunting. One example from the multicultural teacher framework study was the impact of participants seeing clearly the factors in their lives that are impacting them, which required thoughtful follow up from the researcher. However, the time is well spent when an important area of study is seeing little progress, such as minority student success in Los Angeles high schools, or Canadian Indigenous student's graduation rates from secondary programs.

An exemplary before-and-after case study, according to Yin, would make a significant contribution to the field, be complete in studying the phenomenon and the context, offer a collection of extensive and relevant evidence, include the consideration of alternative perspectives, and be written in an engaging manner.

## BLENDING RESEARCH DESIGN

---

Blended research design refers to a research approach that consciously mixes research methods in an effort to get a quality and breadth of information that reflects the complexity of the setting being studied.

Using the history of technological case studies as an example, the following entry describes the progression toward a blended research design that includes both qualitative and quantitative components in the case study approach.

### Conceptual Overview and Discussion

The early history of pedagogical research surrounding technology is best summarized in the meta-analyses done by Chen-Lin Kulik and A. James Kulik. Their studies concluded that computer-based learning approaches show potential for improving student achievement, saving student and teacher time, and improving student attitude toward specific types of schooling. The earliest computer impact work related dependent and independent variables in decidedly positivist research frameworks. The computer was often regarded as the independent variable; dependent variables included final test scores, scores on standardized achievement tests, as well as such things as attitude measures of content and schooling in general.

Those strictly quantitative studies of comparing computer-based learning with non-computer-based learning have more recently been replaced with a trend toward understanding the nature of students' interactions with computer technologies. Neil Selwyn posits that the overreliance on quantitative descriptive methodologies provides a limited perspective, while qualitative and ethnographic studies have the potential to better describe what actually happens in real classrooms, including the changing role for teachers.

The research on the impact of computer technology on classrooms requires an interpretative lens due to the complex nature of classrooms. There are simply too many variables to suggest

direct cause-and-effect relationships in experimental studies. Not only do the computer and user exert reciprocal influences on each other, but the social construction of knowledge through cooperative learning in these settings involves a sophisticated interaction that invokes notions of symbolic interactionism. The nuances regarding the nature of the learning environment require specific research methodologies that blend both quantitative indicators and qualitative introspection. Quantitative surveys of students and teachers allow the researcher to identify trends, whereas qualitative interviews and focus groups unearth the "reasons" for the trends. Qualitative feedback offers windows of understanding and invokes new questions that would never be evident in statistical analysis of surveys. The quantitative data point the researcher in the right direction with respect to what questions should be asked, and the qualitative feedback enriches the understanding of the system through an emergent process of iterative inquiry.

Progressive research design on particular cases of technology integration in classrooms has the potential to allow identification of new learning modes empowered by technology. Case study research has an important role in responding to emerging research typologies. Significant research guidance has been provided by Margaret Roblyer, who has suggested four distinct types of pedagogical research with respect to technology, namely: Type 1—research to establish relative advantages of technology-based strategies; Type 2—research to improve implementation strategies; Type 3—research to monitor impact on important societal goals; and Type 4—studies that monitor and report on common uses and shape desired directions.

### Application

The underlying premise and strength of the blended-design case study is that many sources of feedback are triangulated to yield an understanding of the nature of the learning environment as impacted by the technology.

The case study of technology integration necessarily involves ongoing field notes describing in detail the classroom experience. Typically, teachers and researchers work together as participant observers within an interpretivist philosophical

framework. Following the implementation stage, surveys (composed of Likert scales) are designed, field-tested for ambiguity, revised, and then administered to students. A compilation of the survey data, complete with standard deviation measures, potentially yields statistically significant indications of emergent trends.

Based on the survey data, semistructured open-ended interviews are designed and field tested for ambiguity (Michael Patton). Using the revised interview schedule, a random sample of students is invited to participate in 30- to 60-minute interviews that are audiotaped and later transcribed. An iterative thematic analysis is done through coding of the transcripts (Miles & Huberman). Results are shared with a colleague in a peer debriefing session in an effort to corroborate research findings. An interview with the instructor is audiotaped and transcribed as a means of further reflecting on the aforementioned research data. The overall qualitative feedback is again compared to the survey data to ensure consistency of findings. A member check (Guba & Lincoln) with the students is achieved through several focus groups. In these sessions the researcher compares the accumulated research findings with the perceptions of the larger group in an effort to uncover misconceptions or misunderstandings or to clarify interview dynamics that may have impacted researcher perceptions. Finally, the research lens is carefully considered in order to ensure that the qualitative data are truly emergent and not predetermined in any way.

Ideally, the findings of technology case studies as described above are most useful to the instructor in terms of promoting more effective instruction while yielding generalizable classroom strategies. Although many research typologies share potential, the technology case study offers a unique descriptive account of the impact on pedagogies.

### Critical Summary

The blended research design attempts to combine the most informative aspects of qualitative and quantitative case study data. Triangulating a range of indicators from a study seems a most logical notion, yet the approach is not without critics.

The use of case study for studying technology in classrooms has come under some criticism because of a perceived lack of generalizability. This opinion

has been countered by a marked improvement in the “verisimilitude” of setting descriptions. By being provided a rich description of the learning environment, readers get a palpable sense of the nature of the learning atmosphere and therefore assumes a certain comfort with the relative overlap of the described classroom with their own educational setting.

## BOUNDING THE CASE

---

The very concept of a case study implies the possibility of demarcating, hence drawing boundaries around, the specific case to be studied, but the term *case study* is often used without a clear conceptualization of what constitutes the case or its boundaries. Furthermore, case studies address phenomena at a wide variety of scales, from whole societies through entities like business corporations or social movements, to more specific settings such as prisons or communities, to more focused scenes of interaction or aspects of biography. Thus it may be difficult to

formulate general principles with which to address the bounding of the case, and the conceptualization of such boundaries is recognized to be problematical, a point Robert K. Yin incorporates into his very definition of the case study as a research design.

It is, nevertheless, important to address the different ways in which case studies can be bounded, and in particular to distinguish between commonsense, theoretical, and methodological ways of conceptualizing the spatial and temporal boundaries surrounding specific case studies. These distinctions can be discerned in the literature, though they often remain implicit. Furthermore, each approach illuminates the processes of designing, conducting, and analyzing case studies, though theoretical bounding arguably remains the most fundamental. This entry provides a conceptual overview of the problem and discusses its application.

### Conceptual Overview and Discussion

#### *The Commonsense Bounding of the Case*

Case studies are often focused on entities that have relatively clearly defined spatial boundaries as they are experienced and conceptualized in everyday life, such as the borders of states or the walls bounding prisons or schools. Such organizational boundaries are often clearly marked, monitored, and managed. As a consequence, researchers often have to negotiate their access to such research settings through gatekeepers, the relevant “authorities” or other participants who may grant or deny particular forms of access or approval.

Thus case study researchers must always be sensitive to the ways in which social actors, whether onlookers or participants, themselves conceptualize and act in relation to institutional boundaries surrounding the phenomenon being studied. This may be relatively straightforward for formally organized and strongly institutionalized social entities, but setting boundaries remains a concern where boundaries are more amorphous or contentious, say in relation to a neighborhood, gang, subculture, or ethnic group. In these cases the form, extent, and consequences of demarcation, gatekeeping, and monitoring, and hence the extent and character of commonsense bounding, are more evidently problematical but are still significant, both for the conduct of the research and as a source of analytical insight.

However, researchers must also problematize actors’ understandings of the bounding of any case study entity, including those apparently more solid and clearly demarcated organizations that seem to constitute naturally bounded cases to be studied. Informants may themselves seek to redefine the ways they understand and experience the boundaries of their activities, and it is likely that competing criteria by which actors bound the case are in play. Furthermore, the permeability or even precariousness of established boundaries may be underlined by the flows of people, symbols, and materials that cross them, highlighting the potential for the reconfiguration of such boundaries. Thus the analytical agendas and empirical investigations of researchers are likely to identify social processes that crosscut dominant institutionalized ways of bounding the case, inviting a reconceptualization of the case in terms that are not simply dependent upon commonsense readings of such boundaries.

#### *The Theoretical Bounding of the Case*

The importance of analyzing the scope and significance of the commonsense bounding of cases should be balanced by a critical appraisal of such boundary making. A widespread (though not universal) response among case study researchers is to emphasize the need for a more explicitly theoretical conceptualization of the case under investigation, informed by the analytical themes and research questions that are to be explored. The argument is that particular theoretical approaches inevitably influence the ways in which researchers conceptualize the case they wish to investigate, whether the theoretical conceptualization of such boundaries is made explicit or remains implicit. Thus at each stage of case study research, from the initial design of the study, through the interlocking activities of field work and analysis, to the final write-up, researchers may seek to clarify the implications of their theorizing for an understanding of the bounding of their case.

Such theoretical bounding should permit significant reconceptualizations of the case and its boundaries during the course of the research, though different metatheoretical traditions offer distinctive characterizations of the bases of such reconceptualization. For example, inductivists emphasize that the initial analytical framework

should have a minimal quality, so that fresh theoretical concepts can be generated from a systematic investigation of phenomena within the case. By contrast, critical realists (retroductionists) emphasize the value of a strong initial conceptual framing to guide a process of testing and theoretical revision. In either case, theoretical reappraisal may involve transgressing the initial analytical boundaries of the case, to widen or simply redraw those boundaries in the interest of fresh analytical leverage and theoretical clarification.

### *The Methodological Bounding of the Case*

Theoretical reconceptualization of the boundaries of a case study may suggest that the scope of the study should be extended. Yet practical constraints, including such critical issues as the time frame for the study, the availability of resources, the commitments to funding bodies, and the negotiation of appropriate access, may preclude pursuing any substantial redrawing of the analytical boundaries of the case. Indeed, case studies, by their very nature as detailed investigations of a specific case, always face practical limits on the extent to which they can extend their analytical scope without jeopardizing their strengths as intensive and/or holistic analyses. This makes the methodological bounding of any case study, the way in which the detailed investigation of the case is set within a more summary account of the wider context that surrounds that case, a pivotal feature of the demarcation of the case to be studied.

Such methodological bounding distinguishes between internal contextualization, which is intrinsic to the configurational and often holistic analysis of case study research, and external contextualization, which in more summary fashion places any given case study in its wider context. The methodological implications of this contrast are clarified in Michael Burawoy's discussion of the extended case study method. He suggests that these wider features of the external context are, from the vantage point of researchers studying a specific case, necessarily hypostatized as a set of given conditions surrounding the case, rather than being available for intensive investigation in their own right. Thus methodologically they represent the bounding of that specific case, in a way that continues to register the actual or potential

analytical saliency of these wider features but does not subject them to any detailed processual investigation.

Again, the ways in which such features are conceptualized will depend upon the metatheoretical and theoretical approaches of different researchers, but the crucial point is that they can be registered only in summary and reified terms for the purposes of a specific case study analysis. Both theoretical models and empirical findings may point to the salience of particular external features for an understanding of processes within the case, and thus influence the way in which a specific case is externally contextualized, but inevitably this will constitute an abbreviated framing in comparison with the elaborated internal detail of the case itself. Those features that constitute the external context for any given case study remain open to detailed investigation in another case study, but any such study would itself have to be methodologically bounded by another reified external context, within which the new intensive study would be framed and located.

This characterization of the methodological bounding of case studies through the conceptualization of an external context has important implications for thinking about possible linkages between different case studies. First, research may move from the summary specification of the wider context to a more systematic investigation of some aspects of that context. Thus, smaller case studies may be nested within larger ones, as with studies of subject-specialisms within a school, or workplaces within a local labor market. Here the bounding of the case in terms of its reified external context moves outward as the larger case study takes shape, though the smaller case studies may also retain their own analytical value and distinctiveness.

Second, contiguous case studies may illuminate linkages and flows across the conceptual and substantive boundaries between such cases. Examples would be the linkages between case studies focusing on the development of government policies within the political process and those addressing the reception and implementation of such policies within state agencies, or studies of the operations of enterprises at different points in a design, production, and retail chain. Here specific elements of the external context of one case are translated from reified forces into dynamic processes, opening the

possibility of reconceptualizing the component cases as phases of a more dispersed spatial and temporal process while retaining the virtues of intensive internal contextualization.

### *Spatial and Temporal Bounding of the Case*

This discussion has focused on case boundaries conceptualized in spatial terms, but a parallel set of arguments and distinctions is relevant to the bounding of case studies in temporal terms. Case studies are inevitably temporally bounded, though they may look backward to developments that predate the start of the research, drawing especially on documentary sources and informants' recollections, and they may be carried forward through continuing contacts and revisits. In this context, researchers will attend to participants' accounts of distinctive phases and turning points that may characterize case study developments, but they will also need to engage critically with such accounts in ways that are informed by their own analytical concerns.

Furthermore, practical constraints, including exigencies of access and research deadlines, will also set boundaries around the period that can be covered by detailed case study research and analysis. While the engagement between theoretical agendas and actors' accounts should provide the basis for an explicit analytical bounding of the case in temporal terms, this must also be reconciled with the practical temporal realities of data collection. This is likely to require a methodological distinction between the detailed analysis of temporal processes and sequences within the case and a more summary and reified treatment of precursor, and perhaps also consequent developments.

### **Application**

The importance of theoretical concerns in bounding the case is well illustrated by Paul Willis's study of class relations and schooling. His analytical interest led him to focus on a small group of disaffected students and to study this subgroup across several settings—the school, the street, the home, and ultimately the workplace—that have often been the concern of separate case studies. This provided the basis for his influential analysis of key features of their specific subcultural repertoire and the ways in which this served to reproduce their subordinate class location.

Drawing the boundaries of the case study in this way thus had a coherent theoretical rationale.

In turn, however, Willis's focus on the cultural repertoire of this specific subgroup rather than a broader set of students has been criticized from the vantage point of other analytical concerns, for example those concerned with the less clear-cut responses to schooling of a wider spectrum of "ordinary kids."

Tony Elger and Chris Smith provide a good example of the ways in which specific institutional boundaries may be less clear-cut and more contentious than first appears, leading to an analytical and methodological redrawing of the boundaries of case studies. Their research on Japanese subsidiaries in Britain included studies of four enterprises within the same locality, but they became increasingly aware of the ways in which managers from such firms sought to cooperate to manage the local labor market while workers also operated in response to this wider setting and such attempts to manage it. They therefore reconceptualized their research to include a wider case study of these features of this local labor market while continuing to pursue detailed studies of their four firms.

### **Critical Summary**

It is valuable to distinguish three bases for bounding the case in both spatial and temporal terms. The first, commonsense bounding, involves the documentation and critical investigation of the ways in which research subjects themselves experience and enact the boundaries surrounding the case phenomenon under study. The second, theoretical bounding, involves the theoretically informed investigation and analytical reappraisal of the social relations and processes in play in and around the case, which may involve a refocusing of the research within more theoretically refined or coherent boundaries. Finally, the third form of bounding is methodological, as both the investigation and theorizing of the phenomena under study are partitioned into an intensive analysis of the case and a summary characterization of the external context of the case.

These are distinct though interrelated processes. The most fundamental is a theoretically informed characterization of the phenomenon under study, which draws out the basis on which it can be treated

as analytically distinct from wider social processes. Such theorizing has an ambivalent relationship with actors' demarcations of the social phenomena addressed by the case study researcher, taking seriously such bounding but also problematizing its role in analytical terms. Thus theoretical bounding guides and responds to the detailed investigation of phenomena within the case, but case study research cannot sustain such an intensive investigation if it seeks to trace outward all the flows and interconnections that may appear analytically salient.

Here methodological bounding in both time and space becomes essential if the virtues of the case study research design are to be sustained, because it recognizes a heuristic demarcation between the detailed investigation and analysis of phenomena within the case and the more summary and provisional treatment of phenomena that impinge from beyond the case. As theoretically salient forces or processes cross this boundary they are not lost sight of analytically, but their treatment changes. Such a methodological boundary may well be set to coincide with one recognized by the research subjects themselves, but it explicitly leaves open the theoretical significance of such institutionalized boundaries in relation to social processes that cross-cut them. Finally, this focus on the methodological bounding of case studies facilitates an understanding of the ways in which different case studies may overlap or interface with one another.

## BRICOLEUR

---

*Bricoleur* is a French common noun with no precise equivalent in English. Claude Lévi-Strauss used this term in *The Savage Mind* when discussing magic and mythology. For him, magical thought always had a basis in human imagination, which was rooted in experience of some kind. By definition, a bricoleur is a person who can skillfully and professionally complete a range of different tasks. The way it was used by Lévi-Strauss, and many qualitative researchers following him, it refers to the ability to draw on different analytic techniques with which one is familiar, the choice of which to use being situationally determined.

### Conceptual Overview and Discussion

For Lévi-Strauss, *bricolage* was used to describe a way of knowing the world, one that would draw upon existing ways of classifying objects and practices. The bricoleur by definition is able to perform a number of different tasks, using whatever tools (mental or physical) are at his or her disposal. In this way the bricoleur is seen to possess a “toolbox” of sorts, one that in the context of a researcher contains different knowledges, perspectives, and techniques; in isolation, they may have no apparent use but are there because past experience or exposure indicates they have been, or have the potential to be, useful.

What bricoleur researchers therefore do is keep things in their toolbox in case they may come in handy at some point in the future. Related metaphors

include quilt-maker (who creates a finished product out of scraps of material that otherwise have little use) or jazz improviser (who creates music in unpredictable ways using a repertoire of harmonies and rhythms). Common to these metaphors is a stock of materials from which a finished product is created.

### Application

As a metaphor, bricolage is often used to describe a fluid approach to research that might consist of using or doing several different things. As Norman K. Denzin and Yvonna S. Lincoln point out, there are many kinds of bricoleurs; for example, interpretive, narrative, theoretical, political, and methodological. Whatever researchers are trying to accomplish, they do so in an emergent way as bricoleurs use the tools at their disposal, or add new ones to their toolbox as they become aware of new ones. Bricoleurs can even create new techniques if the ones at their disposal are not adequate for the problems being researched, emphasizing the fact that in much qualitative research, not all decisions concerning research design can be made in advance.

This approach to research is therefore quite consistent with grounded theory and naturalistic approaches, both of which emphasize the need to be open to discovery and sensitive to the way research questions and the context in which they are studied are related.

Theoretical and methodological bricolage was used by Sigmund Wagner-Tsukamoto and Mark Tadajewski in their study of the green consumer, which examined how consumers assess the environmental friendliness of supermarket products. At a theoretical level, their use of cognitive anthropology draws on practical thinking that reflects action-oriented learning and intelligence as well as the information-processing and problem-solving tools that individuals are already familiar with. This permits the investigation of how skillful consumers frame a decision-making choice in relation to the subjective perception and construction of context.

This empirical question was addressed by the use of multiple data sources (interviews, observation, and archival research) providing a form of triangulation that helped minimize social desirability biases in their interviews. Their findings showed that consumers were able to deal effectively with informational deficiencies in the context of their

everyday lives, and that consumers sought out the information that was most easily obtained and relevant to their shopping context.

### Critical Summary

The metaphor of the bricoleur can, however, be a somewhat pejorative one. This comes from Lévi-Strauss's own writing, where the bricoleur was contrasted to an engineer (ostensibly a more technical person), and thus engaged in a "softer" science. That being said, engineers themselves use a certain set of techniques that they obtain through training—their ability to see beyond personal experience and existing stocks of knowledge is anything but certain. The bricoleur/engineer distinction might therefore not be an important one to make.

What is useful in the metaphor of the researcher as a bricoleur is that it has practical application in studying complex phenomena, where researchers' interaction with their subjects, the possibility of multiple realities, and the unforeseen directions research can take are embraced by an approach to research that can follow a number of different paths, not all of which can be planned for in advance of research being conducted. This allows for greater understanding of existing phenomena, and creates the possibility of addressing questions heretofore not considered.

## CASE SELECTION

---

Case selection is the rational selection of one or more instances of a phenomenon as the particular subject of research. The reasons for selecting a case or cases vary from interest in the particular case to theoretical considerations. The relevance of the case or cases for the research objective is the most important criterion for selection.

### Conceptual Overview and Discussion

The selection of cases is an essential part of the case study research design. Because of the intensive data collection methods in case study research, the number of research units can be very limited. Single-case designs examine one unit of a social phenomenon, while multiple-case designs compare 2 to 10 cases. This relatively limited amount of research units puts an emphasis on the researchers' justification of the selection of cases. In contrast to survey research, case study research samples are ideally selected strategically rather than randomly. Researchers need to select cases that give a maximum amount of information about the research objective at stake. For example, researchers look for cases that give a maximum opportunity to falsify hypotheses that are drawn from earlier research. Or they select cases that help to identify the specific conditions and characteristics of a phenomenon that has been characterized in only general terms.

The criteria for case selection depend on the type of research question: descriptive, exploratory,

or explanatory. With a descriptive research question, the cases selected should give maximal information about the specific features and characteristics of a particular social phenomenon. With a single case study, researchers look for an average case; a case that is a typical example of a specific phenomenon. They may also select an extreme case; a case where the social phenomenon is visible in a very pronounced way or under extreme circumstances. By investigating such a case in depth, a detailed and elaborate description of the phenomenon is reached. A descriptive research question may also lead to a multiple-case study design, where a series of cases with common characteristics are studied. The researchers focus on describing the cases separately, rather than looking for common patterns and explanations. The specific features and characteristics of the cases are compared. Alexander George and Andrew Bennett refer to this type of (single and multiple) case study as *ideographic configurative case study*.

With an exploratory research question, researchers select cases that maximize the opportunities for developing hypotheses or theories that explain the social phenomenon at stake. Since this is an inductive research design, screening of the cases has to be based on empirical considerations. The researcher selects a single case that obviously differs from other instances of a social phenomenon—this is called a *deviant case study*. Or the researcher selects a case that seems not to fulfill theoretical expectations, with the aim to use the case for the purpose of developing additional theories—this is called a *critical case study design*. Another multiple-case

study design with an exploratory character is the one George and Bennett call the *building block theory*. Researchers screen all instances of a social phenomenon for subclasses with similar characteristics. By systematically describing and comparing within these subclasses, subtheories may be developed that cover a part of the social phenomenon. These may be added to theories derived from different selections of groups.

With an explanatory research question, the selection of cases is based on theoretical considerations. Here a deductive research design is needed, where cases are screened for their ability to falsify theories or hypotheses that are derived from earlier research. This may be a single case study where the adaptability of a theory is first tested to explore whether a more elaborate testing is needed. George and Bennett call this a *plausibility probe*. It might also be a single case study that tests the ability of more competing theories for explaining the course of events in a particular case. A famous example is Graham Allison's 1971 study of the Cuban missile crisis. Here Allison tests three competing theories that may explain the behavior of the two main actors in this crisis, namely the Soviet Union and the United States. The Soviet Union placed offensive missiles in Cuba and the United States responded with a blockade, rather than an air strike or an invasion. Allison tests to what extent the behavior of these two actors can be explained by considering them like rational actors, like complex bureaucracies, or like groups of persons with a political motivation. This helps to generalize about complex government actions.

There is general agreement that a multiple-case study design offers the best abilities for testing theories or hypotheses because it allows researchers to systematically compare variation between the cases. It is on this aspect the academic debate on case selection has been developed most elaborately. The debate focuses on how to select and compare cases systematically in such a way that theory testing is convincingly served.

The discussion on the selection of case studies goes back to the classical text of John Stuart Mill on the systematic comparing social phenomena. By describing the method of agreement and method of difference, he shaped the base for present-day selection of cases in a multiple-case study research. For using the *method of agreement*, the researcher

selects two instances where the same social phenomenon occurs, but in very different circumstances. By comparing the two cases, the researcher can eliminate all contextual variables that are not necessary for the phenomenon to occur. The variables that the two phenomena have in common are probably the cause of the event that occurred.

When using Mill's *method of difference*, researchers select instances that have the same or comparable circumstances, but that differ in the presence or absence of the phenomenon they want to study. By comparing the cases, the researchers can identify the (small) variation in circumstances of the different cases. The single circumstance in which the cases differ is probably the cause of the phenomenon.

In his influential book *The Comparative Method: Moving Beyond Qualitative and Quantitative Strategies*, Charles Ragin translated Mill's methods in criteria for case study selection. He argues case study research is very suitable for revealing multiple causations of social phenomena. Most social issues that arise do not have a single cause, but are the effect of multiple causes interacting with each other. It is because of the possibility of this multiple causation that Ragin argues Mill's method of agreement is not suitable for explaining social phenomena. Instances that may be caused either by one particular instance or by another particular instance may be falsely judged to have neither of these instances as a cause. He therefore pleads for a double application of the method of agreement, namely the *indirect method of difference*. Researchers should look for instances of a social phenomenon that have only very few circumstances in common, as well as for instances where this social phenomenon is absent. Only if the circumstances that may explain the phenomenon's occurrence are absent in all cases where the phenomenon is absent can a causal relation be identified.

George and Bennett propose an alternative to comparing the variation between cases, by focusing instead on the variation within cases. They state that selection of cases allows for variation between cases in both dependent and independent variables, on the condition that within-case analysis is used to compensate for the limitations in the selection. They present two types of within-case analysis, namely the congruence method and process tracing. The *congruence method* refers to the

researcher formulating or reproducing a theory and predicting the outcome of the circumstances in a certain case. If the outcome of the case is consistent with the theory's prediction, there is a possible causal relationship between the circumstances and the social phenomenon. The method of *process tracing* refers to the researcher systematically examining the intervening steps between initial conditions and the occurrence of a particular social phenomenon. By making a detailed analysis of this process, the list of potential causes is narrowed.

### Application

An example of the use of the method of agreement can be found in a comparative case study research by Inge Bleijenbergh and Conny Roggeband. They test three hypotheses on the relationship between political pressure from women and policy change regarding work–life policies in Western European welfare states. The hypotheses state that the introduction of childcare policies or parental leave schemes can be explained by (1) the presence of women in national parliaments, (2) the presence of a strong women's movement, and (3) equality machinery (an agency or agencies—whether internal or independent—established by the government to stimulate gender equality). By comparing six cases of Western European welfare states introducing childcare arrangements or parental leave schemes between 1985 and 2000, they found that equality machinery was the only condition that was present in all cases of work–life policy change. Further research is needed to examine whether equality machinery is absent in cases where social policy change does not occur.

An example of the indirect method of difference can be found in Pien Bos's work. She examines the decision-making process of unmarried mothers in South India concerning relinquishing their child to adoptive parents. The general theoretical expectation is that unmarried motherhood does not exist in India because it is a cultural taboo. Unmarried women who get pregnant are expected to have culturally no other option than to deny the existence of the child after abandonment. Bos, however, succeeded in tracing nine unmarried mothers who raised their child themselves and compared their stories to ones from 29 mothers who decided

to relinquish their child. She was able to show that the relation between unmarried pregnancy and relinquishment of the child is not self-evident, and identified the ability of women of the lower cultural castes in the cultural context of South India to exercise agency.

### Critical Summary

Because the selection of cases is an important element of a case study research design, it needs to be substantiated carefully in research proposals or research reports. Scholars have to report the criteria they used and the screening process they followed. The selection of cases should be based on the research question, whether descriptive, exploratory, or explanatory, and may be driven by empirical or theoretical considerations. Scholars agree on the preference for selecting multiple rather than single cases to answer exploratory or explanatory research questions.

## CASE STUDY AND THEORETICAL SCIENCE

---

The status of case study research in the social sciences could be considered somewhat ambiguous. The social sciences are theoretical sciences, and theoretical science, by definition, seeks to generalize. Nevertheless, political and social events and phenomena occur only within unique, concrete cases, contexts, and events. This makes the relationship between the generalizing spirit of theoretical science and the uniqueness of case studies problematic.

Case studies, though unique by definition, are implicitly theoretical. They are theoretical since they are done, not out of interest in the uniqueness of selected cases, but because these particular cases are assumed to be typical. Researchers employing case study methodology assume that what is learned from particular cases will be typical, hence generalizable. It is for this reason that case studies, though dealing with unique situations, carry theoretical pretensions. To be sure, case studies are sometimes undertaken explicitly for the uniqueness of the case, and only for descriptive purposes. However, these case studies form a basis for subsequent further exploration and theorizing. Case studies are also undertaken to understand the “outlier” case—that very unique event, organization, group, etcetera, in order to understand what is missing from our more generalized theorizing. These studies also have as their end the intent of developing or modifying theory.

Case study researchers cannot simply take for granted that a given case is typical. The typical character of a case must somehow be established. At the most basic level, informal argument is presented to establish the typical character of a single case. This is done routinely in everyday discourse, throughout the social sciences, and even in the advanced natural sciences. However, in research that aspires to scientific status, something more than informal argument is often required.

### Case Study and Experimental Science

The experimental sciences often serve as an exemplar for case study research, particularly for positivistically oriented researchers. In the experimental

sciences, hypotheses are tested in controlled experiments. Certain aspects of an experimental situation, the initial conditions or independent variables, are specified together with a hypothesis stating the expected outcome. Since the experimenter strives to recreate identical initial conditions for each repetition of an experiment, initial conditions may appear to be generalizations by definition. It is easy to overlook the fact that each experiment is actually a unique case. No two repetitions can be precisely identical. Although experimenters strive to make sure that each repetition is sufficiently identical, they can never be sure of what constitutes sufficient identity. Experimenters are often befuddled by unexpected outcomes due to something unnoticed in the initial conditions of a repeated experiment, or to problems in conceptualization of the experiment.

In the experimental sciences, flaws in initial conditions can be discovered and independent variables revised, while variables in case study research can only rarely be artificially manipulated. Although the focus of interest of a case study can be redefined, as can the variables thought to be relevant, the situation studied, in all its richness and complexity, is beyond the researcher’s control. The researcher may be able to choose variables but, unlike the experimental researcher, cannot manipulate them. Moreover, in experimental situations, variables can usually be isolated; that is, stripped of much complexity. In case study research, while the researcher may *decide not to count* features of a given situation as relevant, they can only rarely be removed from the situation. Even then, the removal of a feature will impact other features in the situation, some of which the researcher may not even be aware. The impossibility of artificially excluding everything but a predetermined set of independent variables makes intellectual work with given situations unavoidable in case study research.

Such problems are not unique to case study research or to the social sciences more generally. Much natural science research must also take the features of the situations studied as givens. Among these are evolutionary biology, paleontology, geology, phylogeny, astronomy, physical anthropology, physical geography, meteorology, and seismology. Much research in such sciences is historical in character. Much of it consists of reconstructions of unique situations that are sufficiently rich in detail

to explain particular events. Such science works with what information is available to create as plausible an explanation as possible. Later it might be completely overturned by new information and hypotheses. Another genre of historically oriented research is genetic in character. It seeks to explain, with sufficient richness of detail, how particular states of affairs came to be.

### Explanation by Typical Initial Conditions

The theoretical social sciences, notes Karl Popper, usually ask questions about kinds or types of events or phenomena, and they almost always make use of a method that consists of constructing types of situations or conditions, that is to say, the method of constructing informal or verbal models. Much of what is called theory in the social sciences, as well as in many areas in the natural sciences, consists of explanation by typical initial conditions. Such generalized typical initial conditions are sometimes called typological theories.

Such models, usually not formalized, are used to explain specific instances of the phenomenon under investigation. When the model fails to explain, it has been shown to be problematic. This does not mean that the model will be discarded. It means only that some explanation must be sought for its failure to explain the particular instance at hand. It is the problem resulting from a model's failure to explain that drives inquiry farther. Various hypotheses may be proposed to explain the problem. The model may be incomplete. The investigator might not be aware that something is wrong with the premises. A model may fail to explain because, for example, it is not rich enough in detail, because it incorporates a faulty assumption, or because of its conceptualization. The researcher can then focus on why the model fails to explain in any given case. Falsification, that is, rendering a model problematic, in this case, plays the role of driver in the growth of knowledge.

Organization theory, role theory, small-group theory, and game theory are but a few examples of bodies of typical social situations used as explanations in social science. When small-group theory is used to explain a particular instance of behavior of a congressional committee, it will be hypothesized that the variance will be explained by typical initial conditions provided by small-group theory. If this

fails to explain the variance, the theory will be rendered problematic. Its failure to account for the variance will require explanation. Explanation will typically be provided by an enrichment or repair of initial conditions. Such an explanation will identify some features of the congressional committee or of its decision situation that makes the deviant outcome comprehensible.

Much general, systematic knowledge in the natural sciences similarly consists of generalizations of types of situations. For example, in meteorology there is systematic knowledge of the characteristic of types of weather systems. In seismology there is systematic knowledge concerning typical conditions under which earthquakes occur. Scientists in such areas of research face problems that are not unlike those confronted by researchers making use of case study methodologies.

The focus of interest in case study research, as in scientific inquiry more generally, does not necessarily or even usually aim at the highest possible level of generalization or abstraction. Scientific problems almost always arise within limited contexts and are often solved or explained by generalizations that apply only within such limited contexts. Most case studies aim at generalizations that are valid only within limited contexts. It's possible to reconstruct the setting of a particular small group, such as a single congressional committee or the Politburo of the Communist Party of the former Soviet Union, or of the method of operation of one particular criminal. Such contextually limited models may be used to explain specific instances of the group's or individual's behavior. This is, in fact, just what scholars who study congressional committees and the Soviet Politburo often actually do. They seek to reconstruct the enduring, the typical features of the institutional setting.

This is not unlike many areas in the advanced natural sciences that focus exclusively on generalizations that hold only within narrowly delimited contexts. There are, for example, many generalizations that are true of dogs but not of other mammals. And there are many generalizations about mammals that do not hold for other vertebrates. Scientists in the advanced natural sciences rarely seek the highest degree of universality of generalization. They usually look for contextually limited generalizations, and are entirely satisfied when they find satisfactory ones.

### Critical Summary

Case study research can thus be viewed as continuous with both experimental science and history, and as theoretical in character. In experimental science, typical initial conditions are held constant, yet initial conditions may range from the very general and abstract to the very rich and specific. A historical study may be done out of an interest in that particular unique event, with the full richness of the event reconstructed. The same study may be hypothesized to be typical, hence generalizable, and be treated as a case study, with attention focused on the typical features of the situation. Interest in a case may be at any level of abstraction, from the unique to the most general.

The word *theory* is used in different ways in ordinary language, as well as in science, and is, to some extent, a contested concept. Some social scientists and philosophers of science would deny the status of scientific theory to the kinds of generalizations of typical situations discussed in the present context. However, if it is accepted that the task of empirical science is to propose generalizations that simplify reality and are testable, case study research can easily be seen as an integral part of the research activity of theoretical science.

## CASE STUDY AS A METHODOLOGICAL APPROACH

---

A case study is a commonly used method among business economists studying firms and organizational behavior. It can be seen as a special research strategy and approach that can use either qualitative or quantitative data, or even combinations of them. The studied cases are usually simple ones, and they are studied in their own special environment. The model can be considered as ideographic. Examples of ideograms include wayfinding (i.e., directional) signs or Arabic numerals, which are used worldwide regardless of how they are pronounced in different languages. The case data can be either longitudinal or cross-sectional. It is important that the setting for research is connected to previous theories, which form a foundation for the analyses and interpretations in the conclusions. A researcher and a research object interact constantly with each other in a case study, and maintaining mutual trust is, therefore, a part of the research process. In the results, the objective is to understand and interpret thoroughly the individual cases in their own special context, and to find information concerning the dynamics and the processes. A case study may also produce hypotheses and research ideas for further studies.

### Conceptual Overview and Discussion

Case study is used in gathering scientific data in different disciplines, in clinical psychology for scientific and therapeutic purposes, as educational tools for understanding pedagogic processes, and as strategies for making sense of sociological and political outcomes, among others. In its early stages the object of case study in the qualitative tradition involved a focus on one company or the stages of an individual. For instance, psychoanalysis set out to understand the inner dynamics of individuals, and assumed that people's mental structures were similar from case to case; in life-cycle analyses of a single company, its inner dynamics of development

were seen as similar to other organizations. The gathered pieces of information constitute qualitative data, which are then interpreted. Qualitative data can be gathered not only as texts but also as pictures or through participatory observation, and a range of other methods. Interviews, for example, especially thematic interviews, are the most common data gathering method for a case study. Using several different methods also enables triangulation, that is, the information received from different data can be compared, which, according to some researchers, like David Silverman, increases validity. Kathleen Eisenhardt argues that it is also possible to use quantitative data alongside qualitative data in case studies. Here research strategies can include experimental research, quantitative survey study, qualitative field study, and participatory observation. Case study is a special research strategy that can bring various quantitative and qualitative methods together.

Case study is often used in the field of business economics as well as in other disciplines. Among them are administration sciences and technical sciences, where the research objects frequently include independent organizational entities, such as companies and other administrative organizations. The studied cases are unique by nature. For example, a company as a business unit forms a natural economic and judicial entity for a case study to examine, and it is relevant to study the organizational, business, and administrative characteristics within the framework of the unit. Public administration organizations are also relevant targets for case study. Organizational behavior, including individual and group behavior in an organization, as well as understanding and explaining it in some work communities, is so complex a task that sometimes only case study can offer an adequate foundation—see, for example, the work of Chris Clegg, Nigel Kemp, and Karen Legge. Case study has been described—in now-classic works by Barney Glaser and Anselm Strauss, by Robert Yin, and others—as an independent methodical and methodological scientific approach.

### *Applications of Case Study*

There are several different research methods for analyzing qualitative data, including linguistic interpretations of texts, which include discourse

analysis, deconstruction, as well as semiotic and narrative analyses. In this latter approach, the object unit of study, that is, a text itself, is a more dominant factor than a particular study's focus on different empirical units, within or across organizations. Overall, the use of qualitative research methodology has become more common in European—especially Nordic and Finnish—research practices in different disciplines. As Timo Toivonen points out, for example, in sociology the use of quantitative research methods has decreased in favor of a growing qualitative tradition following Thomas Kuhn's work on science and its progress through paradigmatic revolutions. The tradition of case study is different from survey study and its generalization viewpoint, since a survey study uses statistical, often multivariate, methods as a support. Case study has collapsed the generalization viewpoint of the quantitative research tradition, and has contributed to the creation of new methods in the social sciences. Some of these methods are originally from the humanistic research tradition, such as the study of literature. However, cases and their analyses also form an independent methodological and methodical approach and a data-gathering model for empirical social study.

As Sirkka Hirsjärvi and colleagues contend, the variable features of qualitative research are suitable for case study where the research data is gathered in natural, real-life situations. Researchers' own observations and discussions as instruments are used more often than measuring, which is viewed as an "indirect" method for assessing rich data. Analysis is inductive by nature, in other words, a researcher's objective is to reveal unexpected issues. Testing the theory or the hypotheses is less important than examining the data in a complex and precise manner. The research set for the study is selected expediently, rather than through the method of random sampling, and the studied cases are treated as unique. In addition, a case study is conducted in a flexible manner, and plans are changed if conditions require it. This way, the research plan is formulated during the research process.

In addition to firms and organizations, it is also possible to study individuals with the case study method. In clinical psychology, case study methods have always been used. The theoretical conclusions of psychotherapy are based on individual

cases in which developmental paths are described in an individual manner. Although it might be difficult to compare the cases with each other, it is possible to find a common theme such as, for example, recovery processes. The traditions of psychoanalysis and psychotherapy have considered case study as a core of scientific discourse. In the psychoanalytical literature, Donald Spence and Roy Schafer, as well as Antero Kiiianmaa, have maintained the research tradition of action research and the use of narratives as data. On the other hand, behaviorist psychology does not significantly base its theoretical development on cases, but may occasionally develop a case as a prestudy for formulating the question of the actual study; and case studies are used in testing preliminary hypotheses. In this behaviorist research approach the use of cases is secondary to the scientific analysis and is not what usually is meant by a case study in the original sense.

The case study approach in business studies differs from the psychological case study in that it does not necessarily aim at the “recovery process” in a psychotherapeutic manner. Management consulting as such may have as its goal this kind of therapeutic outcome but this is not usually viewed as scientific research. The act of consulting does not, however, question the objectives of recovery, and its viewpoint on the whole process is practical. Theory formation is not used as a starting point or an objective of the study. Nevertheless, it is rather common that the case data gathered during the consultation are used in the research of business studies and in other applied sciences, such as engineering.

Cases are also an important means of education. A rich and descriptive case of a firm or a person promotes learning by giving a practical framework for generalizations and theoretical explications. Students can compare their personal experiences on the topic with this framework, and in this way learning becomes an experiential process. Sometimes it is possible to use scholarly case data as teaching material, but both the objectives and the contents vary from case to case. The theoretical frame, the research questions, as well as conclusions drawn from the case are important for case research, whereas pedagogical dynamics, heuristic nature, and the variety of data promoting learning are important in the educational use of cases.

This entry examines a case study from the methodological point of view, and as a special scholarly approach. Case study does not form only one method or set of methods, but is an approach or a research strategy that researchers often use in individual ways to apply to the research setting in question. It is used—as in the work of Jean Hartley and the later work of Kathleen Eisenhardt—in reaching an understanding of the inner dynamics of a unit. Case studies are especially suitable for attempts to understand the variable social phenomena in real-life environments, as Robert Yin argues, in the situation of business management. Also, when existing theories concerning the studied phenomenon are inadequate, a case study can help theory formation by constructing the pyramid “from bottom to top.”

#### *A Concise Presentation of the Characteristics of a Case Study*

There are benefits to gathering data on individual cases. A researcher may gather data by participating in the life of the studied community for weeks, or even years, and in this way receive important and fundamental knowledge that helps answer the research questions. The unique nature of the research object is part of the setting for research, and therefore the objective is not to find universal rules but to understand the case or cases deeply in their own unique environment. Hartley’s work in 1999 examined two different labor strikes, the ways in which they were organized, as well as the strike committees—and found significant local differences between them. It would have been difficult to point out the differences without intensive use of case study, since the means of decision making as well as the decision makers over the period of the strike proved to be important factors on the course of the strike. It would have been impossible to predict these factors beforehand. These individual findings also supported prior theories on strike behavior. Consequently, the nature of the studied unit, its own way of acting and thinking, are important research findings in a case study.

Case study is not a separate method or tool isolated from the research context. On the contrary, as an approach it breaks down the tool-like conception of the use of methods. In empirical social scientific research, the basic unit of research consists

of a researcher and a research object. The researcher gathers data from the research object by using different types of observation and data gathering methods. The research methods used can include interviews, familiarizing oneself with the written material in the research setting, participatory observation, and survey, all of which will produce data. The “information” collected through empirical data gathering is ready to be analyzed or interpreted while preparing the conclusions of the study. It is rather common in case studies that the researcher uses several different data gathering methods, and that the amount of research data received this way may also vary. Therefore, case study can be considered as an approach that the researcher uses when dealing with the research object and gathering data about it. The interpretation of the data is different from the analysis of the typical survey data, where generalization and statistical analyses form the foundation.

The challenges in case study are the same as in every data gathering method. Formulating the research question primarily determines the methodology or the method that is the best for the empirical part of the study. A method is not an end in itself but a means for gathering data. The cornerstones of case study methods are the researcher’s role in the research process, the context in which the research is carried out, connecting the setting for research with existing theory, the use of various methods that aim at increasing reliability throughout the process, and finally, the researcher’s committed and skilful analysis. The approach is both holistic (beginning from an entity) and inductive (moving from the general to the specific), rather than a deductive one, that is, moving from the specific toward the general. The case study model can also be considered idiographic; that is, it tries to explain and understand the individual cases in their own unique contexts.

Case data can be either longitudinal or cross-sectional. Longitudinal data are used in examining change, the life-circle, or the history of a unit. The data may consist of one or several cases. If there are several studied cases, then the research setting can be a comparison of these units on selected dimensions. On the other hand, if a researcher is studying only one single case, the object of the study can consist of history, changes on some measurable dimensions, or the researcher can, for example, explain a phenom-

enon, such as economic returns, with its internal features (see Table 1). The research questions and the setting for the research determine the number and the nature of the cases. The rich research data from a case study give opportunities to quote the interviewees and to bring forward the viewpoint of an actor in the empirical study. A thorough case study is not, however, merely a description of data; it is a logical approach that relies on interpretation and analysis. Finding its roots in the theoretical frame is, therefore, a special challenge for a case study: A clear conceptual frame forms a foundation for interpreting the results of a case study.

If the data consist of several cases, a winding approach that moves from one case to another may be best. In this approach the researcher gathers data from one case, interprets it and asks new questions based on the interpretation, and then moves on to another case in order to find answers to these questions or to deepen his or her interpretations. It is possible to move on to a third case, to a fourth case, and so forth, until the most crucial and the essential questions of the study have been answered. A process-like progression is different from the way in which a set of studied units is formed in the beginning of the research, and in which data are gathered despite the results of the different cases. The methods show the idiographic nature of a case study in an excellent manner, as well as the fact that the researcher and the research object interact in a different way than, for example, in a survey. The researcher is a learner, and the learning process is the foundation on which the data gathering and interpretation are built.

### *Conducting a Study, and the Critical Points in a Case Methodology*

A researcher who uses a case study method benefits from the rich store of qualitative *methods* available. Further, the analysis of a case study also has particular characteristics that make it unique. A researcher and a research object interact intensively with one another in a case study, and a study proceeds as a process, from one stage to the next. The cornerstones include the following: (a) Selecting the case study objects, (b) ensuring entrance to the case site, (c) outlining the theoretical frame as a foundation of the study, and (d) data gathering, processing, and analyzing. These are not only the

**Table I** Application possibilities of a case study

	<i>One Case</i>	<i>Several Cases</i>
Cross-sectional data	An internal tension in a setting for research; comparing dimensions as a research object	Comparing the cases on the selected dimensions
Longitudinal data	Studying change in the selected dimensions	Comparing changes between the cases on the selected dimensions

practical questions but also the factors affecting the validity and reliability of the study, and they are significant when evaluating whether the researcher has actually studied the phenomenon he or she intended to study, and whether the conclusions have been drawn in a reliable manner. The research object is a phenomenon, such as cultural change in a company. An object phenomenon itself can be approached through various research settings and theoretical emphases. During the research process the phenomenon can be framed, for example, so that the unit that will be analyzed consists only of the ideals of the management style, guiding principles on how to do the work, and the evaluation of work considered important by the firm's personnel—as in the 1991 study by Iiris Aaltio-Marjosola. The research data are interpreted in a way that simplifies the change of the organizational culture through these ideals.

In principle, the research problem and the research questions determine the methodology and the methods with which the phenomenon is approached. They determine the typical company or organization for that particular study, or a special case and the phenomenon to be examined to the fullest. Also, the number of cases studied depends on the research questions. Studied cases are often found through the researcher's own network. For example, he or she may have worked as a trainer or a consultant and may draw on organizations that he or she knows well. It is important to have the whole organization's support, in addition to the support of the management and perhaps of the owners, and here prior knowledge and association with the organization can be of great help.

From the beginning it is important to agree on the responsibilities between the researcher and the management of the organization, especially on how

personnel are informed about the research. It is characteristic of a case study that the researcher and the organization studied are in close contact with each other, usually for several weeks and sometimes even for years. It may be useful to name a contact person inside the organization who will help with the interview schedule and in finding required documents. Building a good relationship with the organization, as well as maintaining it, is important for the researcher using a case study method. Changes in personnel or management may occasionally change the schedule. For example, the management or the ownership of the company may change during the research process, and in such situations it may be important to prove the commitment of the previous management or the owners to the study, through contracts, minutes, or other evidence.

Building and maintaining trust between the researcher and the study's target company is at least as important, if not even more important, than formal arrangements. Occasionally one hears about cases in which changes in ownership prevented the researcher from releasing some of the most important findings of the research. Nevertheless, the characteristics of a case study, that is, its process-like nature, long duration, and close contact with the studied company, make a project rather different from the typical survey study, in which the data are gathered in an agreed manner and the analysis is done outside the company. The researcher gathers, interprets, and analyzes case study data during the course of the case study, and depending on the findings, prepares the next stage in a way that gives additional information about the studied phenomenon.

In a case study, it is at least as important to choose a theoretical frame with specific literature, as it is in any research using a qualitative approach.

A conceptual frame gives the material a focus, with the help of which rich and varied data can be controlled by the researcher. Some form of limitation in terms of such things as time frame is necessary in every research setting; otherwise the data gathered in a case study may turn out to be too extensive and unwieldy. The study's focus and question formation need to be reasonably well developed when the researcher first contacts the target company, as does the linkage to prior concepts and research results. However, even though a focus is useful, it is also useful to retain the researcher's open-mindedness for learning, which is characteristic of case study. Occasionally, a case study has surprising results, a prior paradigm is seen in a different light, or the study reveals a paradox with respect to prior knowledge. Understanding the internal dynamics of the research object, to which the case study methodology gives opportunities, gives space for various results.

Hartley's work provides illustrative examples of gathering data based on a case study. A researcher is often uncertain of how to begin, who to interview, which documents to read, and which meetings to follow. At first the researcher may create a general picture of the organization and its structure, and conduct a few interviews to gain some level of orientation. These will help to clarify and specify the sources required for the research. For example, the work rhythms, organizational pressures, and their occurrence that are characteristic of a particular company may be seen in these preliminary chartings. These pieces of information will prove to be helpful when outlining the interview schedule. Also, the most important people and research methods for conducting the research become clearer. Triangulation may also increase the reliability of the study.

Gathering the research data requires systematic behavior, and the researcher should ask whether enough informants have been interviewed for the study, or if other respondents with a different perspective are needed, and why. Should there be more data for a specific assumption or a conclusion? Sometimes people who have resigned from the company may give significant information that is needed in order to understand a specific crisis and to gather alternative viewpoints of the situation. Ad hoc data can sometimes come up in situations such as an accidental meeting in a coffee-room

or in a hallway, and create new ideas for continuing the study or for throwing new light on the researcher's current interpretations. Therefore, it is good for a researcher to leave room for flexibility and surprise: Intuition has an important place in case study research.

How extensive should the research data be? There are expenses in the process of data gathering, both temporal and economic. Gathering the data, as well as recording them, takes time. Transcribing recorded interviews, that is, transforming them from audio to a written form of research data that then can be processed in several different ways, should be done as soon as possible after interviewing. Glaser and Strauss recommend keeping a research journal and writing down observational, methodological, and theoretical issues during data gathering. The saturation point is reached when an additional interview does not bring any significant new data, or the researcher feels that the same issues are repeated in the informants' speech.

#### *Data Processing and Conclusions*

The way research data are processed depends on the nature of the data. There are computer programs for interpreting qualitative data that search for regularities in the text and act as an instrument for interpretation. A case study usually consists of several different types data, sometimes both qualitative and quantitative. The analysis of the research data, as well as the data gathering, is done in an iterative manner. While the data are being gathered, they are also being evaluated, and therefore a partially theoretical construction is done during the gathering stage. Yin's work describes data processing as a process in which the data are first sorted around themes or questions, after which the data's suitability for the categories is examined more thoroughly. It may be helpful to use statistics, tables, and figures to summarize the data. The categories may change after the analysis, if it is realized that the results require different interpretation. An individual case, for example, may not fit into any of the categories, and this requires reinterpreting all the data and probably reformulating the categories.

The data gathered through case study enable rich and varied descriptions. Stories and interview quotations from the data are very common; especially

in the first stage of analysis they help in simplifying the extensive data for further processing. In the later stages of processing, the data are further summarized, and the researcher draws conclusions, for which the data are searched. The contextuality of case data is an essential foundation for interpretation. The data are interpreted with the object of understanding the individual case through the elements found in its own environment, whether it is an economic, a cultural, or a social environment.

A theoretical frame and a strong conceptual foundation are especially important elements of an analysis. Case study data and their analyses are used by researchers to develop theories on prior phenomena by pointing out paradoxes, bringing forward new observations gained from the thorough analysis, and pointing out the varied relations between the individual cases and their environments. Answers to the research questions are not sought in generalization but through intensive and contextual case observations.

Case study methodology is sometimes criticized because of supposed generalization problems. A survey produces data that are analyzed through statistical methods with the objective of producing data that can be generalized. A causal research setting is common. In this research setting, the dependence between the variables is determined from a data sample by using the methods of multiple variables. However, a survey is also based on the researcher's evaluation and interpretation. When using a factor analysis the naming of the factors is a subjective event, in which both the researcher's own consideration and his or her prior knowledge and concepts about the studied phenomenon will influence the outcome. The interpretations do not come "purely" from the data.

The case analysis does not aim at generalization but rather, through the researcher's attempts, to understand and interpret the individual cases thoroughly in their own special contexts. The researcher examines data about dynamics, mechanisms, processes and internal "regularities," and does so in a way that comes closer to the ordinary conception of generalization. The objective is to reach conceptions and understanding by moving from the specific toward the general.

The whole concept about the requirement for generalization can be criticized. If a state or an issue is described on a very general level, the content

of the description may prove to be extremely superficial. The phenomenon dissolves in its generality. Instead, understanding a state, process, or dynamics on an individual level and in its own environment may produce understanding, which helps to illustrate a scientifically interesting phenomenon in a more extensive manner. When concentrating deeply on the problems of the research object, the case method may also produce hypotheses and research ideas for further studies, whether they are qualitative or quantitative by nature.

### Application

#### *Example 1: Comparisons Between Hospitals and Cooperative Work Societies*

Case study has been commonly used in business economics research when studying firms and other organizations, which are administratively, economically, and judicially independent entities. Case study applies well to the study of organizational behavior, also, because the target phenomena consist of various types of behaviors, which are examined in their own environments. A context, that is, the environment, is a crucial basis for interpretations in a case study. The following example examines two different dissertations in which a case study has an essential role.

Jari Vuori compares the ward cultures of public and private hospitals in a study conducted in 1995. The objective of the study is to define the concepts of private and public organization and to study the mythology behind the conceptions of private and public healthcare, as well as to compare healthcare in private and public hospitals in order to find their idiographic differences. Case study can be considered as a method, since the target of the comparison consists of the meanings that the personnel of two different organizations attach to the phenomena of administration, life, death, and work. Selected organizations were chosen as examples of private and public hospitals so that they are relatively similar to one another as far as the size and type are concerned. In this respect, case study forms a basis for the research.

Vuori's study is qualitative in nature, and its primary data gathering method is in-depth interviews. The data on life and work were gathered in interviews as well as completed with questionnaires and collected stories from the participants.

Nurses and doctors also drew organization maps in which they described the social hierarchy of the organization from their personal points of view. In addition, meeting memoranda and personnel magazines were analyzed. The question of the differences and similarities might be between the ward cultures of private and public hospitals was selected as the research problem. Further, the objective was to discover how valid the myths of private and public organizations and healthcare were. An existential–philosophical approach was used as a methodological background philosophy for the method, since the study focused on the contents and inner life of the research subjects, and the way they gave meaning to their experiences. The study concentrated on the meanings that the research subjects gave to the studied dimensions.

The results show that the cultural differences between the hospitals were smaller than the prevailing myths indicated. Generalizations that public healthcare would be less oriented to the individual, of lower quality, and economically less profitable, proved to be untrue in the meanings that the staff had for their work. Similarly, the results pointed out that workers who had experience in both private and public hospitals showed varied conceptions, whereas those who had worked only in public hospitals tended to think “of course private healthcare is better.” This is surprising and paradoxical. As is typical of case study, this result emerged during and out of the research; it was not part of the research questions. The study does not aim at generalizing the results to the whole hospital sector, which would be an insurmountable task, even for qualitative research. It does show the dynamics of research questions in a way that is typical of case study and enables a process-like research in which the questions become more and more accurate as they are answered during the research process. A conceptual frame of reference forms a strong foundation for the research. The work includes a thorough examination of the selected methodology, study of meanings, and the examination of the research on the culture in the areas that are important when forming the research question. The backgrounds of the studied cases are also presented in a way typical of a case study, that is, a conceptual analytical examination is done on the questions of what public and private healthcare are, and how clearly they can be distinguished from one another. The studied cases represent both the public and private sectors in hospital administration. They

are used in an attempt to understand the differences between these organizational forms on a more general level, beyond individual cases.

### *Example 2: Employee-Owned Firms and Work Cooperatives*

Another interesting case study is Eliisa Troberg’s focus on the “relevance of transaction cost and agency theoretical concepts to the management of knowledge intensive co-operatives.” This study examined employee-owned firms and work cooperatives, especially the way in which they have been organized, and their organizational culture, management, leadership, motivation, and employee-owners’ commitment to the firm. The target of the study consists of four different case companies. Existing research shows that work cooperatives are formed in order to minimize transaction costs. The study is a comparative case study. First, two work cooperatives are compared with a similar single-owner business. Second, work cooperatives are compared with a limited company that is owned by its employees. All of these business forms are cooperative enterprises, but the administrative structure varies from case to case.

The primary result of the study revealed that each work cooperative had a strong organizational culture and set of values. Shared values and the notion of the work cooperative as a flexible organizational form act as the basis of commitment and motivation for the workers. The work cooperatives had been established to allow members to combine their skills and networks, and to reduce the transaction costs of marketing. Worker turnover was low because of the high level of motivation and commitment. Passive members were identified as those causing problems. In one cooperative, decision making proved to be slow and the members had problems reaching a consensus. Thus it was felt that a socially integrating management model might reduce these problems, giving good results as was the case with another one of the studied work cooperatives.

The researcher substantiates her methodological decisions and the use of case study by stating that there have been only a few studies on work cooperatives and that constructing a theory by examining case companies in an intensive manner

is justified. In addition, the target phenomena of the study—culture, socially integrated management, and commitment, as well as their relation with the administration—are best studied with an intensive case examination. Case study methodology also is emphasized in selecting the cases. The selected firms were similar enough to be compared. Therefore, the size and the field of the companies are important factors, and the researcher decided to concentrate on the fields of education and consulting. The number and age of personnel as well as the geographical location of the companies support the comparative nature of the cases. Both of the work cooperatives had been in business for several years and had between 10 and 20 members. The studied firms, one of which was owned by the personnel and another owned by an individual person, were also well matched.

*Example 3: Comparison Between Managerial Careers in Information and Communication Technology and the Paper Business Sectors*

Pia Heilmann's 2004 study compares careers in the information and communication technology (ICT) and the pulp and paper industries. The main themes of the research are managers' careers in Finland, and business sectors that determine careers. The purpose is to examine managers' careers, and to describe and compare career paths between the two most important business sectors in Finland: the ICT industry and the pulp and paper products industry.

The main research question of the study is: How do managers in ICT and the paper business sectors construct their careers? Heilmann was interested in examining whether there were any commonalities in how managers' careers unfold in these different working environments. What are the main factors in manager's lives that direct their careers? Do they differ depending on the business sector? These questions are approached with the help of metaphors: career anchors and career ladders.

This research represents a qualitative multiple-case study, as outlined in Yin's 2003 work. Two business sector cases are compared in the selected dimensions. The primary research data were gathered in 2002 through interviews with 30 managers

in Finnish ICT and pulp and paper companies. The interviews were held in three companies from the ICT sector and three companies from the newsprint industry. The first interviews in each company were conducted with directors in order to gather basic information concerning the organization and to discover the organizational viewpoint to career development. Then, five suitable managers in each company were picked with the help of company directors. The determining factor in selecting interviewees was the varied career development of the engineering managers. Data from the focused interviews were analyzed according to theme and type. In every interview, a short questionnaire on career anchors was also given. Results of the questionnaire were analyzed with the Mann-Whitney Test. These secondary data complemented the interview data.

Results showed that reflections of a boundary-less career are apparent in the ICT sector (see the work of Mirvis & Hall). Careers are developed without limits and formal hierarchical progression. Persons working in the ICT sector are eager to develop their competences and care about their employability. The career of an ICT manager progresses by means of increased competence, as the manager is offered new and challenging positions. However, the traditional, hierarchical career model cannot be rejected for the ICT sector, because increased competence often pushes careers upward in the hierarchy. The conception of career is more relational than hierarchical because the new position is related to the former position and to the person's training and work experience. In the ICT sector, career paths and particular positions are seldom ready-made. Open positions are usually for Software Engineers at the starting level in an organization. After entering the organization, a person's career development is based on interaction between the organization and the employee. The course of positions is based on the manager's competence. A post does not necessarily exist in the organization chart where the manager can direct his or her next step. Career development is done by formatting new duties in interaction with the manager and the organization, by giving him or her new opportunities and challenges, power, pay, and title.

Hobbies are an important factor among ICT managers when they make decisions concerning the area in which they want to pursue education

and to work. In the ICT sector, work and education overlap, whereas in the paper sector full-time work begins immediately prior to or just after graduation. In this research, the ICT companies work mainly on customer software projects where software applications are designed, tested, and documented. It is a world with deadlines and contracts to complete. The work done in ICT companies has to be integrated with customer schedules and regular business hours. There may be several unfinished projects continually under way where the same person may work as a member of various projects in various capacities. The organizations mainly use a matrix organizational structure offering flexibility and effective allocation of resources. The pressure for change is continuous: Changes in technology and tools assume constant training and retraining. Working hours are 37.5 each week, and work is done in the daytime. There may be a need for temporary extra hours during tight periods, but if overtime work is continuous it is a sign that something is wrong in the project design and resource planning. Diversity is seen for the future of the sector. According to one ICT director, reorganizing is going on in the ICT business: Some companies will die, some will consolidate, and some will change their business philosophy.

An individual's first position is usually found through networks or from company homepages. ICT sector careers begin with either part-time or fixed-time contracts in the position of Software Engineer. Most people taking the software developer position are undergraduates in technical universities working part time during their studies.

The paper sector, as a part of the forest cluster, represents mainly a traditional, hierarchical career development format. The organization has a formal organization chart that shows all of the managerial positions. Managers planning their future career development can easily discover possible positions in the organization. Vacancies are usually announced in internal or external job markets. Development of one's own competence is also common and desirable in the paper industry. Managers begin their careers as a specialist in some area of the industry and then usually move upward toward general management tasks.

In the paper sector it has been common to recruit the children of personnel as summer

trainees. This makes it possible for individuals to become acquainted with the paper business for the first time. It is on the basis of this experience that many managers become interested in the paper sector and aim for technological degrees. Studies and work alternate but do not overlap. During school terms, students studying in the field of pulp and paper production concentrate on their studies; they work only during summer holidays. Generally, students in this field finish their studies before they start full-time work. Careers in the paper sector generally begin with thesis work or with the first permanent position. The first permanent post is generally found through an advertisement in a newspaper, usually the main national newspaper. The first position is usually as a specialist working in a particular, strictly defined area. Paper managers construct their career in one paper company. Job openings are often announced formally on the company's intranet. Paper managers expect their tasks to change every 5 years. Traditional career thinking is strongly in evidence in the paper sector, but there can also be seen signs of new career thinking. Managers in the paper industry, for example, assess and develop their own competences and follow what happens in the labor market outside their own company.

The researchers noted in the examples above applied case study methodology in their own ways to the cases discussed. One study has two target companies, the other has four; one examines two different business sectors. The comparative setting becomes easier when the cases are similar by size and industry. Also, the theoretical frame is well constructed in each study, which gives a solid basis for the conclusions drawn. The researchers also used interview quotations, case descriptions, and detailed individual observations, which is typical of a case study.

### *Research Ethics*

After the research data have been gathered, the researcher leaves the organization after agreeing with the contact person(s) on how and when the research report will be delivered to the case organization. The personnel may need a different kind of report than the management. Feedback

discussions and even seminars concerning the research results are also possible. It may be emotionally challenging for a researcher to leave an organization after spending a long time gathering data and to move on to the more abstract research stage, which doesn't have the social rewards often received from interviews and participatory observation. Responsibility for the organization's future is in the hands of the management and the interviewed persons—the researcher's responsibility is to carry on processing and outlining the data, and to move on to the conclusions, which should be beneficial to the personnel of the case organization.

The researcher may reveal acts that are extremely important for the organization and for the interviewed people. Occasionally, researchers may find themselves in an awkward situation when the organization expects them to give consulting advice on a difficult situation, for example, who should be fired or promoted during a reorganization. The researcher is committed to use the data for research purposes and for the best interest of the whole company, and therefore it is ethically justified to refuse to answer these types of questions. The researcher is often asked to deliver a summary of the research results to management, and sometimes this extends to the employees—at least to the people who were interviewed and wish to receive it. However, the researcher's role differs from that of a consultant, which is also evident in that the researcher is not paid for the report.

Writing the report itself often leads to many ethical questions. The data presented in the study should be anonymous; any personal information that reveals the source of the data should be deleted. If the sources of information have nothing against it, however, identity information is allowed. Names are usually not necessary, just background details such as gender or position in the organization. Sometimes researchers need to be critical, because they found dynamics in the organization that are harmful; in that case, good research ethics require that these data are shown in the study, not concealed. If the researcher has signed a confidentiality agreement, this should be noted in the study. The researcher is on the side of the whole organization, thus the research should not serve the interests of a limited group

of people. Human and individual consideration is needed.

It is both polite and ethical to care about people's feelings during the research process. Good interviewing techniques are needed when using the case study method. The interviewees should be given enough time to think over their opinions, they should not be encouraged to be too open in the process or be pushed in a way they might regret later. When the researcher is able to use multiple documents and materials as research data, the possible limitations for their use should also be considered. It is safe to let someone in the organization read the manuscript in order to avoid possible difficulties later.

Research ethics questions are at least as important in case study methodology as in any other research approach. These deal with questions of establishing the study, writing the study report, and, later, using one's own knowledge concerning the case. In a case study, the researcher becomes more like an insider in the organization compared to more objectivistic research approaches, and the more the researcher is accepted as an insider, the more ethical consideration is needed.

### Critical Summary

Case study methodology can be a rich source for understanding the multiple structures that support and sustain organizational life and business units. Its strengths are in its ability to gain an insider's viewpoint during the research process, the more in-depth and nuanced findings based on that, and in its flexibility in using different methods. Its challenges are in the theoretical framework and in the development of concepts based on empirical findings. When these are taken into account, fruitful and nuanced research results are possible, and through the study it is possible to gain an overall and holistic picture of the research object.

In addition to the study conduction itself, during the research process the researcher can gain a lot of understanding and skill that would not be possible using a more distant methodology. Ethically, case study research can bridge academic research and work-life.

## CASE STUDY AS A TEACHING TOOL

Case studies are commonly used as research tools, and the case study method is a distinguished instrument for bridging the gap between theory and practice in classes. Students learn to apply their theoretical knowledge through the case study process of diagnosing, deciding, and acting. An adequate preparation of the cases and the course outline is essential for educational success, with consideration of the cases' exemplarity, clearness, and practical orientation. The case outline should include the presentation of the case and its individual background, the task of researching and analyzing information, the process of decision making and argumentation, a following (group) discussion of the results, and the final comparison with practice. For further development of teaching cases, more successful criteria-oriented research is required, as well as a sustained education and training of teachers and lecturers.

### Conceptual Overview

A Chinese proverb says: "Tell me and I will forget; show me and I may remember; involve me and I will understand." Based on this idea and the practical experiences of Gustav von Schmoller, James Spender established the Bureau of Business Research at the Harvard Business School, which can be classified as the origin of so-called teaching cases. In this context, in 1908, the following statement (according to Kaiser, 1983) could be found in their university calendar: "In the course of Commercial Law, the case system will be used. In the other courses an analogous method, emphasizing classroom discussion in connection with lectures and frequent reports on assigned topics—what may be called the 'problem method'—will be introduced as far as practicable" (p. 12). Since then, teaching cases have been an inherent part of the business and management curriculum all over the world.

These cases are characterized by the intention to present complex circumstances and problems that are close to reality (e.g., from business practice) in such a practical way that learners are motivated to discuss the particular contents.

This way of teaching enables learners to apply practical problems and circumstances; they are

required to establish a direct relation between these real-world issues and theoretical information. The case consists of a content part followed by a question part. There might be just one question or several, depending on the case and the subject. The complexity of the cases differs depending on the level (undergraduate vs. master's level) and the subject.

An example would be that students read a case about a specific start-up company and then have to rate the start-up's success using the background of their knowledge about start-up success factors. Another case may be a detailed market analysis of the soap market in one country with the task of creating a new brand for a producer of consumer goods.

### Application

#### *Case Study Design*

The goal of teaching cases is that the learner has to analyze problems and situations, gather and evaluate information, interpret facts, develop alternative solutions, and come to final solutions, alone or in a group. Depending on the case and the teaching outline, the case study may have a given solution or the goal may be an open-ended discussion.

To reach the intended effect for the learners, these teaching cases must fulfill certain conditions and prerequisites. For this, Bernd Weitz proposes three essential criteria: exemplarity, clearness, and practical orientation.

*Exemplarity* means that the study must exemplify not just an arbitrary and subjective case, but also one that is objective, unique, or representative. *Clearness* requires that cases are not trivial; on the contrary, they have to make use of all possible and appropriate alternatives of illustration for a comprehensive understanding. This demands holism, traceability, visualization, and supplementation with additional information. The last point, *practical orientation*, aims for the highest integration of theory and practice for an integrated learning process.

There are certainly more criteria that can be taken into consideration; for example, how up to date a case study example is. However, the relevance of any particular criterion depends on the individual case and the general teaching goals.

### Teaching Case Process

To work with case studies in classes, the following general procedure can be proposed:

- ◆ Presentation of the case and its background
- ◆ Gathering and analyzing information
- ◆ Decision making and argumentation
- ◆ (Group) discussion of the results
- ◆ Comparison with practice

First, the teacher has to decide whether the students should solve the case on their own, in pairs, or within a group. In most instances, group work is recommended because this is the most common situation in practice. Moreover, personal skills and effective group behavior can be further developed as well.

Within the first phase, learners are confronted with the description of the case and its content. They read about the case situation, ramifications, and persons involved and have to capture the underlying problem. It is important that all participants clearly understand the contents and the problems, as this is the prerequisite for the success of the next phase. Ideally, the students have enough time to search for the required information on their own. Otherwise, the teacher can offer additional information for the case solution in advance. Based on the collected information, the groups start to analyze the contents with regard to the case study questions.

The process of decision making means that there should be more than one possible case solution, providing enough space for creative solutions by the participants. After a specific case solution is selected, an appropriate discussion of pros and cons and ideas for further consequences is required. In concluding, the learners have to make an active decision for a certain option and support their choice. The bigger the group, the more complex this process step can become.

For traceability, all these phases should be recorded in writing, though the procedure may vary depending on the specific case.

The discussion of the results is moderated by the teacher. All groups or persons present their case solution, including the reasons they arrived at this result. The other participants are invited to question the presenting team's solution critically and to evaluate their results. With this discussion, further development of the case can be reached, as well as an active integration of all learners.

Given a particular case outcome, the presentations of the group can be compared and accordingly

discussed. For example, if the real-world outcomes of the case are known, the participants can learn that some decisions from practice are not always the best or obvious solution, but rather the result of specific decision processes within these companies. Finally, group feedback is recommended.

### Critical Summary

Although there is a long history of using case studies in teaching, there is little research on how successful this practice is. Some often-mentioned limitations are:

- ◆ In most areas, only a small variety of real teaching cases exists.
- ◆ Companies are unwilling to give insights into their processes to the public, as they fear a loss of control over know-how or advantaging their competitors.
- ◆ Creating and working with teaching cases requires high involvement of the case author and the teacher in class.
- ◆ Learners do not accept cases, as they may fear having less time for other necessary coursework (e.g., exams).
- ◆ Lack of experience, both for teachers and learners, may prevent them from using teaching cases.

Nevertheless, teaching cases offer a highly effective method for including students in the learning process and making a transfer between theory and practice. More research is needed regarding the success factors of teaching outlines, moderators, and group sizes. Moreover, schools need to offer explicit courses for teachers to learn how to deal with cases in classes. Then, teaching cases will be an increasingly integrated part of future education.

## CASE STUDY DATABASE

---

A case study database is a primary method for organizing and warehousing case study data and analyses—including notes, narratives, tabular material, and documents—in a single space. This entry describes the elements of a high-quality case study database as well as the four compartments embedded in most case study databases.

### Conceptual Overview and Discussion

Prescribed by case study methodologist Robert K. Yin, a case study database is an increasingly useful analytical tool that strengthens the reliability of case study research. Although most books on field methods have not recognized case study databases as an important methodological technique, the failure to craft a formal database may be deemed a major shortcoming of case study research. Instead of creating a case study database to establish a clear audit trail, many researchers engaged in case study research do show their data separately from the final case study report, it is blended into the

narrative of the report. To offer only case study data that is blended with the narrative in the final case study report leaves a critical reader with no opportunity to examine the raw data that led to the case study's conclusions.

Although there is no uniform approach to establishing a case study database, the quality of a database is evaluated by the extent to which other researchers are able to understand how the collected data support claims made in the final case study report through perusal of the database. A formal case study database not only enables researchers who are not involved in the case study project to juxtapose data collected and cited in the database with claims made and conclusions drawn, but such a database also increases the reliability of the overall case study. Thus, to prepare a case study database that is reliable and usable for secondary analysis, a high level of clarity and specificity within the organization of the database is required to ensure accuracy of the data and data analysis.

### Compartments Embedded in Case Study Databases

There are four compartments embedded in a case study database: notes, documents, tabular materials, and narratives. Each compartment is described in the subsections below.

#### Notes

Case study notes, the most common compartment of a case study database, are messages derived from interviews, observations, and/or document analysis completed throughout the case study research process. While notes may be generated in a variety of ways (e.g., handwritten, typed, or audio-tape format), the most convenient way to organize and categorize notes is to ensure that they are easily understandable and accessible for later examination by research and nonresearch team members.

While there is no precise, systematic way in which case study notes must be organized, a common technique is to divide notes into the major subjects as outlined in the case study protocol. Aligning notes with sections of a protocol helps the researcher to maintain the level of organization necessary to construct a clear and usable case study database. While organization and clarity are important to achieve for secondary analysis,

researchers need not spend excessive amounts of time rewriting case study notes derived from data collected. Rather, case study notes should simply allow readers not involved in the research process to understand how the data support claims and conclusions.

### *Documents*

Similar to case study notes and other compartments embedded in the case study database, the primary objective of case study documents is to make these materials readily retrievable and understandable for subsequent inspection.

As case study documents are collected throughout the research process, one useful way to organize documents is to develop an annotated bibliography. Such annotations would facilitate storage and retrieval so the database can later be inspected and/or shared with other researchers involved and not involved in the original study. To establish further convenience and wider usability of the case study data, converting documents into portable document format (PDF) copies will make for efficient electronic storage. Notwithstanding the efficiency of PDF files, researchers are not required to trouble themselves with the time and storage space associated with the construction of electronic documents.

### *Tabular Materials*

Some case study researchers interested in organizing and storing data for subsequent retrieval use tabular materials either collected from the site being studied or created by the research team, which may represent a third compartment in a case study database. These materials might include survey or other quantitative data and counts of phenomena derived from archival or observational evidence. Similar to other means of storing data in the case study database, it may be most convenient and useful to organize and store tabular materials in an electronic case study database, as opposed to separate documents and data filed in separate places.

### *Narratives*

A final compartment embedded in most case study databases is the construction of narratives—an analytical procedure that involves documenting

the answers to the questions in the case study protocol. During the process of writing narratives, the researcher needs to cite or footnote relevant evidence—whether from interviews, documents, observations, or archival evidence—when generating an answer. While developing narratives in response to case study protocol questions facilitates the production of a clear and concise preliminary analytical process, the narratives may or may not need to be included in the final case study report.

In short, case study narratives offer researchers a method to converge data with tentative interpretations. The researcher or research team may then use the narratives embedded in the case study database to compose the case study report, and readers may be able to understand the sources of evidence that directly support the claims and conclusions offered in the final report.

### **Critical Summary**

Establishing a case study database is a helpful technique given the complex and multifaceted nature of case study research. While inordinate amounts of time should not be devoted to making a case study database professionally presentable, the data embedded in each compartment should be understandable to researchers involved and not involved in the case study. The primary characteristic of a quality case study database is that citation of data clearly connects to claims made in the database as well as in the final report. The construction of a case study database also establishes a warehouse for subsequent cross-case analysis. While the inclusion of a case study database in case study research is not widely noted in the literature on field methods, these databases represent a technique that increases the reliability of case study research that merits more attention.

## CASE STUDY IN CREATIVITY RESEARCH

---

*Creativity* refers to the capacity to invent or craft novel and useful products that are valued as such by a peer group. The term applies to many domains of human experience, such as the fine arts of painting, sculpture, music, literature, film, and theater, and the applied arts of architecture, advertising, and mechanical and engineering design. Creativity also characterizes many other aspects of life such as scholarship, leadership, and teaching. Progress of society, which is characterized by the new and useful, can benefit from creative citizens though creativity may not always lead to positive ends. Hence understanding creativity should be of great interest to social scientists, persons in government, and educators, in addition to those who are interested in creativity from the standpoint of basic research. While creativity is generally understood to characterize highly original minds, sometimes referred to as *big C* creativity, the concept can also apply to everyday problem solving. The latter may lead to new and useful behaviors for an individual but would not receive external recognition from a professional standpoint. Given the significance of creativity to society and individuals, it is natural that creativity research is becoming a burgeoning field, as represented by several scholarly journals such as *Psychology of Aesthetics, Creativity, and the Arts*; *Creativity Research Journal*; and *Journal of Creative Behavior*.

### The Significance of Case Study to Creativity Research

Because creativity is by definition typically associated with the unique characteristics or ability of an *individual* and because case study also emphasizes the concept of *individual*, case study lends itself particularly well to addressing the questions of creativity research, particularly questions that require a wealth of data about a single person or created artifact. Foremost among these questions is, “What is creativity?” This question breaks down into several others: To what extent is creativity an innate characteristic that cannot be trained? Or conversely, to what extent can or must

creativity be trained? What are the stages of development that characterize creative behavior? Are there stages of creativity that apply equally to all domains in which creativity is manifested? Are there universal attributes of creativity that characterize all individuals within a culture or across cultures? How can creativity be fostered? What is the role of the gatekeepers who admit or reject a new work as worthy or not of the term *creative*?

### Types of Case Study Research in Creativity

As the concept of *individual* is central to both creativity research and case study, research in creativity has benefited and can benefit from case study approaches. The cases examined can be creative persons, their products, or processes. The data may be acquired through interview, archival materials (e.g., diaries), analysis of creative works or performances, and observation of the process of developing the work. The case study approach is characterized by the acquisition and interpretation of a wealth of data about the individual case rather than the administration of personality or problem-solving tests to large numbers of individuals. The case study, however, can entail both qualitative and quantitative data.

Like other methodologies, case study approaches to creativity have strong and weak aspects. For example, interviews with creative geniuses have the benefit of providing information from a valid source; however, the information may entail subjective bias on the part of either the participant or the researcher. Case study approaches that analyze the developing work itself can serve to reflect the underlying mental operations associated with creativity. The focus here can be sketches and revisions of the same work. Here too, however, investigators may be biased to find what they are looking for. Simply because one is analyzing something inanimate versus something animate does not protect against subjectivity. Analyses of autobiographies or biographies of a creative individual can also provide a useful source of data, but again the source of the information may be subject to bias. Finally, case studies have been carried out in which individuals are challenged to solve a specific problem, where the specific problem is the case. The limitation here is that only one problem or a limited number are explored.

Howard Gruber developed the evolving systems approach (ESA) to address the need for direct study of the creative process of eminent individuals in an appreciation of the complexities of an individual's entire life. The approach arose from Gruber's earlier extensive study of the writings of Charles Darwin as well as interviews with Jean Piaget. ESA focuses on the case of the exceptionally creative individual in order to understand the nature of the creative process. It has six features:

1. It is directed to both the creator and the creation of the work, rather than to personality and other psychometric tests.
2. The investigator must have sophistication in the domain of the creation and creator being studied.
3. Sufficient original material (as in available sketches, diaries, letters, interviews) must be available to permit the exploration.
4. Within an overall holistic approach, focus is placed on meaningful part processes such as imagery, metaphor, and problem-solving that make up the whole.
5. It aims to create the dimensions of significance for describing the creative process and characteristics rather than checking off traits from a list.
6. It conceives of the case as evolving and nonhomeostatic, allowing for the influence of external factors over time, such as changes in societal views.

### Application

ESA has been applied to the lives and works of Charles Darwin, Albert Einstein, and Michael Faraday, for example, and has helped to demystify their creative processes while preserving the uniqueness of the experience and contribution of each individual. As pointed out by Doris Wallace, a collaborator of Howard Gruber, this type of analysis emphasizes the genius of each creator within multiple contexts of work as a whole and in the context of the body of work, the professional milieu, family and personal life, and the sociohistorical period.

A somewhat less comprehensive, more quantitative case study approach taken by psychologist Robert Weisberg has focused on obtaining quantifiable data, such as the time between initial practice

in a domain and the success of the first creative work. As a specific example, the first concerto of Mozart's that can be regarded as his own composition, and not based on the work of other composers or his father, came about nearly 10 years after his commencement of instruction. An analysis of Mozart's scores, including original music manuscripts with the annotations and handwriting of either Mozart or his father, supports the observation. Similar information regarding the timing of Picasso's highly regarded artwork, or even the Beatles' period of initial popularity in the 1960s, arises through the same case study approach. Such an approach that collects data systematically before, during, and after a creative act of interest can reveal that apparent sudden popularity has actually a gradual onset involving hundreds of hours that comprise years of dedicated practice. Thus the case study data gathered for creativity research may either support a view that the creative process and disposition to originality is inborn or support the alternative view that the creative process depends on 10 years of dedicated practice. The case study approach will also emphasize the importance of exposure to ideas available to the creator that may account in large part for a discovery or breakthrough that received recognition.

Weisberg's case study of Thomas Edison, for example, emphasizing the importance of timing and chance events, could take into account his early experience with scientific experimentation and the profession of telegraphy that ultimately provided him with the background required to invent the phonograph. Given the similarity in principle between the phonograph and the motion picture recorder, experience with the phonograph privileged Edison's position as the inventor of the motion picture camera, as compared to the position of Alexander Graham Bell, an inventor who lacked a critical piece of information. As much as Bell might have imagined such as thing as a motion picture camera, he lacked some critical experience that was required to solve the problem of how to do it. Here the case study, as carried out by Weisberg, focuses on the time course of activities and emphasizes the reliance on extensive training and the availability of useful information that together lead to highly regarded creative outcomes.

Having an even greater emphasis on quantification of data is the historiometric analysis developed

by Keith Simonton applied to all the works of an individual author, playwright, poet, or composer. As an example, Simonton developed a popularity measure for the 37 plays of William Shakespeare based on such factors as the frequency of stage performances, the number of complete audio recordings, and the number of scholarly critiques. He aligned these scores and their rankings with the estimated composition date. From these data he was able to show which external (e.g., historical or biographical occurrences) and internal (themes of the work) factors led to the eminence of the dramatic work. A similar approach to determining popularity was taken in analyzing the 154 Shakespearean sonnets. Further analysis of the style and word choice within these popular examples helped to reveal the essence of Shakespeare's creative genius, for example, in designing the rhyming couplet to tie together the loose ends of the preceding lines without adding surprising or unusual words. The case, then, begins with Shakespeare but ends with analysis of particular outstanding examples of his work.

Another case study approach to creativity research has focused on detailed analysis of successive recordings of the preparation for a professional performance. Primary investigator Roger Chaffin audio-recorded all practice sessions of professional pianist Gabriela Imreh, who was learning the *Italian Concerto* of Johann Sebastian Bach with the aim of making a professional recording of the piece. In a longitudinal case study of more than 50 practice sessions during a period of approximately 40 weeks, the attention of the artist shifted from one type of performance cue to another, as indicated to Chaffin through introspective report. The later sessions contained increasingly polished performances and revealed variations that would be regarded as creativity. The variations were adaptive to the particular contingencies arising at each rehearsal, and suggested that the creativity of the performer is activated with every serious practice or performance session.

Creativity in performance arts such as music, ballet, or theater can focus on either the creativity of the performer or the creativity of the composer, the choreographer, or the author of the script. There are several case study methods for exploring this talent. Examination of sketches may entail looking for subtle differences between inks, for

example, so as to determine what ideas were notated first, and how the ideas changed. In the musical realm, many composers, including Beethoven, have left sketches behind. Although these are sometimes almost illegible, music scholars have assessed these works for clues about the composer's creative process. One such project on Beethoven sketches has been carried out by William Kinderman of the University of Illinois, while a more contemporary resource of 20th-century musical sketches has been published by Patricia Hall and Friedemann Sallis. Such material complements other historiographic or biographical data and provides a picture of the creative act and person.

In searching for universal dimensions of creativity, a case study approach was taken by David Cropley and Arthur Cropley in which teams from a class of engineering students were presented with a creative problem-solving task—that of designing a system using only a mousetrap to move a wheeled vehicle a fixed distance. The authors graded the outcomes in accordance with a set of indicators (relevance and effectiveness, generation of novelty, elegance, and genesis) and kinds of products (routine, original, elegant, and generic) that had a variety of possible effects on the beholder (e.g., redefinition enables the beholder to see new uses for a familiar object). The most original out-of-the-box solution met all the criteria of creativity, but the authors suggest the importance of case studies from many other fields such as foreign languages, history, mathematics, and physics so as to validate the universality of the dimensions. It should be noted that concepts of creativity can be applied to both the extraordinary genius and the ordinary person, the distinction referred to by Mihaly Csikszentmihalyi as *big C* creativity versus *little c* creativity. Thus case studies of creativity can be carried out with children and with ordinary adults, although the focus might be regarded as being on problem solving, or in the example of children, as precreativity rather than creativity as it is most often understood.

### Critical Summary

Because both creativity research and the case study emphasize the individual, the case study method lends itself well as a tool for collection and analysis of the rich data required for creativity research.

The cases in such studies can refer to the creative individual, the created product, the process of creation, and the problem to be solved. They are not mutually exclusive and, ideally, the study will include all of these. Within this area of research, there are numerous ways of exploiting the case study methodology, each having strengths such as obtaining a vast amount of data, and weaknesses such as the difficulty of retaining objectivity and staying focused on the key issue of interest. The combination of results from the various methods that touch upon the person, product, and process thus will lead more quickly to new facts and conceptualizations than will taking only one of the perspectives. The accumulation of data through case studies and the appropriate analysis will help to determine the nature of creativity and the ways of fostering it. The data can be acquired from both the creative genius as well as the ordinary person, and the knowledge acquired from the research may ultimately have application to all individuals.

## CASE STUDY PROTOCOL

---

A case study protocol is a formal document capturing the entire set of procedures involved in the collection of data for a case study. A complete protocol will include the following: (a) The procedures for contacting key informants and making field work arrangements; (b) explicit language and reminders for implementing and enforcing the rules for protecting human subjects; (c) a detailed line of questions, or a mental agenda to be addressed throughout the data collection, including suggestions about the relevant sources of data; and (d) a preliminary outline for the final case study report.

### Conceptual Overview and Discussion

The desired protocol should cover the range of behaviors to be followed by case study investigators throughout their field work and their interactions with those being studied. In this sense, a protocol is broader than a data collection instrument, which may be limited to the line of questions (as in a survey instrument) or to measures (as in an experiment).

### *When and How to Use a Case Study Protocol*

Case study investigators need to develop their protocols in at least two stages: a preliminary stage and a final stage. The preliminary stage occurs *after* the case(s) to be studied have been screened

and selected and after any pilot case study has been conducted. Those earlier steps may themselves have been the subject of formal documentation and procedures, but the steps should have been completed before drafting the preliminary case study protocol.

The preliminary protocol, though still reflecting tentative plans and ideas, should nevertheless be contained in a formal document. Case study investigators will need this document as a central part of their submission to their institutional review board (IRB). The IRB will review the protocol in approving the entire case study research project. Because the IRB will ascertain whether the planned case study will satisfactorily follow all of the necessary procedures for protecting the human subjects, IRB approval is mandatory before any research can proceed (not discussed here are the related documents that investigators will have to submit to their IRB).

The IRB's review may result in changes to the case study protocol. The version meeting with their final approval then represents the final stage of the protocol. This final protocol now contains the procedures to be followed in conducting the actual case study.

The preliminary protocol may have been developed alone, especially if the case study is to be conducted by a single investigator. However, if the planned case study is to involve more than a single investigator, and especially if others are to serve as part of the case study's field teams, the preliminary protocol should have been jointly produced by all these people. Although the lead investigator may still draft the bulk of the protocol, the others need to understand the protocol thoroughly. Such understanding best takes place if all team members have had an opportunity to contribute to its development.

Such familiarity with the preliminary protocol will be carried into the formal training process that then takes place with the final protocol. When two or more people are to be involved in doing the case study, the preferred case study training assumes the form of a working seminar, with participants discussing the contents of the protocol, their implications in relation to the case study's line of inquiry, and the relevant evidence bearing on the line of inquiry. The training process therefore becomes the opportunity for all of a case study's investigators and field team members to develop the same

collective understanding of the inquiry to be undertaken. Naturally, if the case study has only a single investigator, the training will assume the form of a self-study.

Whether seminar or self-study, the case study protocol should ensure that case study investigators have a deep understanding of the substance of the case study. This goal differs from that when using other methods, such as surveys and experiments, when some of the team is likely to include research assistants who may need only limited knowledge of the content of the research. In this sense, satisfactory mastery over the case study protocol requires all of the investigators to become "senior" investigators. Such a level of expertise is needed to cope with the discretionary choices that may arise during the process of collecting the case study data.

### Application

A typical case study protocol might have five sections. Section one would briefly overview the case study, its main research questions, the case(s) to be studied, and the broad data collection strategies. The overview also could clarify whether the case study is to be part of a larger, multiple methods study, and if so, the main goals of the broader study.

Section two of the protocol should describe how the case study team will contact key informants, make field work arrangements, and specify other procedures to be followed throughout the data collection process. The importance of making all of these steps explicit is that every case study is likely to have unique procedural needs. The ensuing research will be more reliable if the procedures can be anticipated and then documented in the protocol. The descriptions may include specifically scripted words or instructions for team members to use.

Section three of the protocol should discuss the specific concerns to be raised and monitored in protecting human subjects. The section again may include specifically scripted words or instructions for the team to use in obtaining informed consent or otherwise informing case study interviewees and other participants of the risks and conditions associated with the research. The discussion of the concerns and the presentation of the scripted words need to follow any guidelines issued by the IRB.

Section four of the protocol is its most substantive section. The section may be divided into subsections,

each representing a major part of the case study inquiry. In turn, each subsection should consist of a series of questions to be investigated by the case study team. These questions are to be part of the team members' mental agenda.

The questions in section four are not the questions to be posed to case study key informants or other interviewees as if they were the respondents in a survey. In this sense, these questions do not represent scripted words. On the contrary, the protocol's questions are directed at the case study team, posing a query for which the team is to gather evidence. Each question may be accompanied by a brief list of hypothesized sources of evidence for answering the question, including clues about identifying the relevant sources. For instance, the list may direct team members to specific participants to be interviewed, specific documents to be accessed, or specific field observations to be made.

Overall, team members need to learn the material in section four as thoroughly as possible. Adding to this chore can be another feature of section four which is anticipating the data collection choices that might emerge during field work, and conjecturing how such choices might be addressed and settled. Whether the protocol formally contains this information or not, the case study training should include a careful discussion of the choices.

Section five of the protocol should then present a tentative outline of the final case study report. Although the substantive contents will not be known at this juncture, an outline indicating the relative emphasis to be given to the various topics in section four will provide important guidance for data collection. For instance, if the case study report is to contain a detailed chronology of the important events in a case, team members will need to collect more data about this topic even if it had been represented by only a single question in section four. Conversely, section four might have had several items covering the formal organization of the case being studied (as in studying an organization), but the main reporting need might only be a carefully constructed organization chart.

### Critical Summary

When engaged in case study research, the development and use of a case study protocol is imperative. A well-designed protocol will define questions

of study, remind researchers about field procedures, and identify data to be collected. Most important, the protocol should explain the relationship between the questions of study and the data to be collected. If needed, important adjustments to the case study protocol can be made throughout the field work. Key to understanding a case study protocol is that it is not a field instrument. The protocol's language is directed at the researchers involved in the case study, not potential interviewees or field informants. Thus, the protocol is not to be carried around in a physical sense but as a plan held in the researcher's head.

## CASE STUDY RESEARCH IN ANTHROPOLOGY

---

Case study research in social/cultural and linguistic anthropology consists of intensive periods of ethnographic field work, which are then written up and analyzed. Such case studies, termed *ethnographies*, are central to anthropology as a discipline. This entry considers the definition, origins, and history of the case study in anthropology; the impact of this particular type of case study on the discipline; some controversies surrounding it; and its wider application.

### Definition and Formulation

It is difficult, in anthropology, to find an exact definition of *ethnography*, and there is much disagreement about what exactly an ethnography constitutes. Broadly speaking, it can be defined as "the art and science of describing a group or culture," which involves the ethnographer writing about the routine, daily lives of people. Alternatively,

it could be defined as studying behavior in everyday contexts, engaging in “unstructured” (although not unsystematic) data collection, using a small number of cases, and analyzing these through interpreting the meaning of human actions. Ethnography can also be said to be characterized by “naturalism”; that is, understanding naturally occurring human behavior in context as opposed to through artificial settings or structured interviews. While this sort of research technique is also found in other disciplines, such as sociology, it is not as central to other disciplines as it is in anthropology.

The lack of structure, and the focus on particular cultures, may explain the difficulty of defining ethnography. The nature of the study is guided by its specific research problem, techniques, duration, budget, and theoretical underpinning. Furthermore, ethnography is unique in that the researcher and his or her identity become basic parts of the research process itself, and yet, a balance must be achieved between maintaining enough involvement to get the sense of life in the culture under study, and maintaining an objective distance for the purpose of analysis. The ethnographer’s personal experiences effectively become central to the research process, but are restrained by the impersonal standards of observation and, to the extent that it is possible, objectivity. Many, however, would argue that the lack of agreement on the nature of ethnography is one of its greatest strengths, giving it a degree of flexibility and richness.

The anthropological case study is also expected to develop a balance between the emic (insider’s) and etic (outsider’s) perspectives on the culture under study. Again, however, there is much variation in the degree to which each is favored. While some ethnographers focus upon obtaining an objective approach, of chronicling events and behaviors, others argue that the key to ethnography is in conveying the insider’s perspective on his or her own culture to outsiders. In writing terms, ethnography is generally characterized by thick description and vivid, narrative-style content, with the aim being to capture the complexity of human life.

While the image of ethnographic research that frequently emerges in anthropological literature is of a rugged, scientific anthropologist immersed in the culture under study, the reality is often less romantic. It has been noted, principally by Renato Rosaldo, that the result of British anthropologist

E. E. Evans-Pritchard’s efforts to edit, as it were, the outside world out of his case study of the Nuer, in the name of objectivity and of defining the “true nature” of Nuer culture, resulted in a kind of contextless image that ignores the historical specificities of the time. The belligerence that Evans-Pritchard identifies as typical of the Nuer was, he argues, most likely a specific condition inspired by British encroachments upon their territory at the time of Evans-Pritchard’s field work. Most anthropologists also rely substantially on translators and informants with an unusual social background, frequently those used to dealing with outsiders, even social scientists. Some researchers also challenge the notion that anthropologists can truly become immersed in the culture they study—or, indeed, whether this is desirable (e.g., for anthropologists studying criminal subcultures). While immersion in the field is desirable, the degree to which this immersion is possible, or conveyed in research, varies.

There is also some disagreement over what the overall purpose of this type of case study should be. Ethnography developed under a functionalist paradigm, where it was seen as a way of ascertaining the fundamental nature of social organization, norms, values, and so forth. More recently, many anthropologists consider that their main role should be cultural interpretation, or the ability to explain the practices, beliefs, and frameworks of reality of a given culture from its point of view. Some researchers argue that, in the absence of set criteria, ethnographies should be assessed in terms of their naturalism, their validity (i.e., how “true” the account is), and their relevance to social issues and scientific research more generally.

## Historical Development

### *Genesis of Ethnography: 1600–1921*

While it may be argued that anthropological case studies date back to the 17th and 18th centuries in the form of reports by missionaries and traders on native peoples, at the time that anthropology was established as a discipline in the 19th century, anthropologists were not generally supposed to go into the field themselves, but to analyze the data gathered about other cultures by colonial officials, missionaries, professional ethnographers, and so forth. Toward the end of the

19th century, however, more intensive field work began to be done by anthropologists themselves. Franz Boas, for instance, did a full year's field work among the Inuit in 1883–1884, and spent about 40 years, off and on, working with the Kwakiutl. Boas was unusual in this, however, and considered ahead of his time. Another exception is the 1898–1899 Haddon expedition to the Torres Straits, which differs from the modern norm in being a team effort comprising a number of researchers who had a relatively short period of time to do their research. Intensive field work was not practiced by many of the key figures in 19th-century anthropology.

#### *Development: 1922–1969*

Bronislaw Malinowski is often cited as the “founder” of the profession of social anthropology, for his establishment of the focus on intensive field work in an exotic community as a central defining facet of the discipline. Malinowski's own account of his experience is that he had planned on doing short-term field work in Australia, but, due to the outbreak of World War I, he wound up exiled to the Trobriand Islands for several years (due to having enemy alien status) and discovered that through intensively involving himself in the culture, he was able to develop more rich and comprehensive accounts of the Trobriand Islanders' practices than earlier anthropologists had achieved. The reality involved rather more planning than this, however, as Malinowski already had some theories about the benefits of long-term field work before this, and ethnographies based on sources other than intensive field work with a single community continued to be considered acceptable. Nonetheless, the practice of ethnography rapidly became popular, ultimately proving central to the discipline.

#### *Modern and Postmodern Ethnography: 1970–Present*

In the 1970s and 1980s, critiques were leveled at the concept, principally accusing anthropologists of colonialism and of exploiting peripheral groups. As James Clifford put it, in popular imagery the ethnographer changed from a sympathetic, authoritative observer to an ambitious social scientist making off with tribal lore and giving nothing

in return. Anthropologists also began to question whether it is possible for ethnographers to remain neutral, detached observers, and to what degree research can be influenced, consciously or unconsciously, by the researcher's bias and mind-set (e.g., Derek Freeman's 1983 critique of Margaret Mead's classic studies of Samoa). This led to the development of the postmodern movement in ethnography, aimed at critiquing the format and nature of the case study, and taking into account the researcher's own identity, issues, and so forth, such that it is clear that all accounts contain bias and that the researcher's position may not be that of the people being described in the ethnography.

In the 1980s and 1990s, the postmodern movement in anthropology questioned the nature of ethnography, whether it is a form of scientific analysis or simply of literature/literary criticism, or even autobiography. A controversial case in the 1980s involved the novel *Shabono*, initially presented as a real memoir of a European's life with the Yanomamo tribe of South America, but later proved to be a fiction. Nevertheless, the piece was so well researched and factually accurate that it suggested that one could produce a convincing and accurate ethnography without living in the culture under study, thus challenging the claims of some anthropologists that ethnography possesses a particular kind of “authenticity.” Many studies also argued for an awareness of the limiting factors of anthropological data-gathering techniques. Also controversial was the fact that many researchers were doing work with transnational groups, in which a traditional field study is not possible, and researchers must adapt their methods, for instance doing a multi-sited study or adopting the transnational lifestyle of the informants as much as possible. This, however, incurred critiques from others questioning what the anthropological endeavor should involve, whether there was anything new in the postmodernists' arguments, and whether anthropology would not be better served by an increase in reflexivity (i.e., researchers maintaining a continual awareness, when doing research, of their own interests and biases, and of the context in which they are operating) and academic rigor instead.

#### **Examples**

It is worth considering some of the major types of anthropological case study:

- The *traditional descriptive ethnography*, consisting of a description or exploration of a whole culture or subculture, usually considering as many aspects of the culture's or subculture's organization as possible. This approach is comprehensive, but is usually found in early to mid-20th-century anthropology. A prime example is Edward E. Evans-Pritchard's *The Nuer*.
- The *focused descriptive ethnography*, which is similar to the first but focuses on a single aspect of it (kinship, adolescence, visual arts, etc.), such as Evans-Pritchard's *Witchcraft, Oracles and Magic Among the Azande*.
- The *event study* or *incident study*, in which the focus is on a single event or incident; the analysis usually focuses on what that single incident can reveal about the wider society. Many linguistic anthropological studies are of this kind. Examples include Audrey Richards's *Chisungu*, a study of a girls' initiation ritual.
- The *microethnography*, sometimes taking the form of a life history, focusing on presenting a single informant (or one or two informants) and understanding their society through them; this was popular among postmodernist anthropologists. Examples include Marjorie Shostack's *Nisa: The Life and Words of a !Kung Woman*.
- The *meta-ethnography*, in which the ethnographic experience itself is taken as a case study, with the anthropologist and his or her experiences as research subject. One example is Elenore Smith Bowen's *Return to Laughter*.

While it is difficult to determine precisely what defines the case study method in anthropology, then, one can identify particular genres and techniques within it, allowing one to generalize to some extent about the method and its influence.

### Methodological Implications

Although there is general agreement on the elements of ethnographic field work, the interpretation of these elements is more varied. While participant observation is usually seen as the main basis of ethnographic work, it can be, and usually is, augmented by the use of audiovisual equipment, interviews, collection of cases, genealogies, quantitative surveys, and so forth,

and, more recently, by online work. Despite this, participant observation is still regarded as crucial, relating as it does to the anthropologist's ability to observe, experience, and analyze these experiences according to a particular critical framework.

Again, however, the nature of this participant observation can vary. While many popular and academic guides to doing field work emphasize that the researcher should be a stranger to the group, ethnography can be conducted by people who are already members or partial members of a group; for instance, former schoolteachers doing studies of classroom activity. Ethnographers also may not live directly among the people under study. Margaret Mead, for instance, lived with an American naval family near the village that was the subject of her research, and Michael Agar argues that his field work among drug addicts in New York is as much an ethnography as his earlier "traditional" field work among farmers in India, even though it would have been highly dangerous for him to actually live with the drug addicts or share their lifestyle; consequently his participant observation was limited to visiting with his interviewees as an explicit outsider to the community.

It is generally agreed, however, that maintaining a sense of reflexivity and context is essential, situating the observer in the field and considering his or her social identity. It is also important that ethnographic studies carry with them a sense of context, intellectual and otherwise. Martin Harris, for instance, notes that pioneering anthropologist Meyer Fortes's conclusion that the Tallensi were an acephalous society (i.e., a society without leaders) in fact stems from his failure to consider that these people had been defeated and dispersed by the British, and that under normal circumstances they had a more recognizable leadership structure. Ethnographers thus must situate themselves and their informants in context to as great a degree as is possible while still maintaining confidentiality.

### Critiques

A number of critiques of ethnography have been raised from within the discipline over the years. To begin with, the technique has been accused of leading to a false sense of scientific generalizability, as in the well-known case of the Human Relations Area Files, founded in 1937. These aimed to classify and

organize cultures around the world based on kinship systems, economic organization, and so forth, in a large database from which general conclusions could then be drawn. The problem was that this frequently led to drawing false and meaningless parallels and ridiculous generalizations, as human culture is not so easily classified. Some have argued, on the other hand, that the lack of scientific generalizability is a strength of the discipline. Furthermore, societies do not easily lend themselves to the kind of decontextualization that facilitates generalization. However, a lack of scientific rigor can observably lead to a degree of “siloing” among anthropologists, where most are experts in only a small area and find it difficult to generalize from this area or to engage in interdisciplinary work. A balance must therefore be struck between generalization and a focus on specificities.

Critiques have also been leveled at the value of ethnographic methodology as a scientific technique: that by studying small numbers, the case study’s findings are not generalizable; that studying behavior in a natural setting rules out the researcher keeping control of the variables; and, finally, that the case study itself is nonreproducible. One might counter these points by arguing, first, that anthropology is not about generalization, but about making theoretical inferences (as discussed above); second, that ethnographic techniques can document lived experience in a way that experiments cannot; and, third, that reproducibility isn’t always possible in natural science, either, nor does it guarantee validity. It is also imperative to consider ethical issues, such as the researchers’ responsibility to their informants, the desirability of giving something back to the studied community, withholding sensitive information from publication, and so forth.

There is also the issue of researcher bias, given the identity-focused nature of ethnographic field work. Michelle Rosaldo argues that anthropology up until recently, and still, was characterized by unconscious biases toward and prejudices against women, making the results of most classic studies far from objective without anybody realizing it. A number of anthropologists, including Ruth Benedict and, famously, Margaret Mead, have been accused of having massaged the facts to fit the theory being tested, or to have had that theory influence their perceptions. Emic and etic perspectives can also

sometimes become confused and difficult to separate. Many guides to ethnographic field work discuss strategies for reducing, or at least increasing personal awareness of, bias among field-workers. This can also lead to the issue of multiple realities, or the *Rashomon effect*, whereby many people in, or observing, a society can develop different perspectives on it, leading one to question which is the “true” one, or, indeed, if we can speak in such terms at all. It is worth noting that, if we reflect upon our own culture, we would see that there are many perspectives on it as well, raising the question of why we expect other cultures to be different in this regard.

Finally, as noted above, anthropologists are often, still, accused of colonialism and/or of perpetuating colonialist attitudes through the nature of field work. The structure of anthropology still frequently involves privileged Westerners observing and describing those in non-Western countries and/or the underprivileged in Western nations, but seldom in reverse (a rare counter example can be found in John Ogbu’s study of an American inner city by a Nigerian anthropologist). Then, further, there is also the question of who is the intended audience of ethnography? This critique has been tempered somewhat in recent years, as it is increasingly recognized that ethnographic research, even in traditional settings, is much more complex than this, and the anthropologist may not always be as powerful or as privileged in the field as some might think. However, academic research is still not divorced from geopolitics and accompanying power relations. Anthropology thus has to maintain a degree of awareness of the power relationships that form a subtext to ethnography.

### Impact on Anthropology

Ethnographic research has had a defining impact on anthropology as a discipline, such that the use of ethnography is one of the points of identity of a modern anthropologist: The discipline is, effectively, built around a specific form of case study. Although quantitative methods are also used by anthropologists, even in studies of hunter-gatherer societies, they tend to be popularly regarded as a secondary activity, and Harris argues that ethnography is crucial to anthropology, noting that the rise in anthropology in the 19th century was spurred by

an increase in ethnographic material. More recently, Nigel Barley refers to anthropologists romanticizing the ethnographic experience, noting that when Malinowski's diaries were published, many were shocked at the revelation that even the father of ethnography had felt alienation, frustration, and even racism when engaged in his supposedly impartial and comprehensive studies of the Trobriand Islanders. Mary Louise Pratt refers to anthropologists defining ethnography in contradistinction to older, less specialized genres, such as travel books, personal memoirs, and journalism. Ethnography is thus the defining trait of anthropology, even though anthropologists may use other methods, and other researchers employ ethnography.

The emphasis on ethnography has also shaped the discipline in other ways. Anthropology tends to focus on qualitative over quantitative evidence, and on finding "authentic" voices or experiences, with concurrent debate over what, exactly, constitutes "authenticity." The defining trait of anthropology might also be said to be a favoring of cultural rather than biological explanations for human activity, which may also be another artifact of the case study focus of the discipline. It has, in some ways, also led to the prioritization of a single research method above all others. Malinowski notoriously strongly advocated the ethnographic method to the point where he was deeply critical of anyone who practiced less immersive research methods, even though "ethnographic fields" are themselves artifacts of history, shaped by colonialism, economics, and, latterly, globalization. Furthermore, it means that the personal attributes of the researcher take on a significance greater than they usually do in most other disciplines, perhaps leading to a greater sense of introspection on the part of anthropology as a whole.

This has also led to a fragmentation of the discipline. Anthropology, with its divisions into gender studies, African studies, Japanese studies, Native American studies, and so forth, lacks the degree of integration seen in other disciplines with similar subdisciplines (e.g., sociology, management studies), due in part to the focus on the case study as a unique, qualitative experience. This may be partially blamed on the difficulty of equating ethnographies on any sort of empirical level, given the great degree of variation from case to case. The focus on ethnographic case studies thus gives

anthropology a distinctively flexible, fragmented, qualitative character.

### Impact on Other Disciplines

The anthropological case study method has been used to good effect in other disciplines. Sociologists, for instance, have been known to make use of it: in particular Erving Goffman, who self-identified as an urban ethnographer and spent much of his career engaged in deep-immersion participant observation in, among other things, hospitals, mental institutions, and (somewhat controversially) casinos, with the result that his work is both criticized for a lack of quantitative rigor, and celebrated for lateral thinking and innovative takes on human behavior. M. Rosaldo also acknowledges the contribution that ethnographies can make to gender studies through encouraging researchers to reinterpret earlier conventional accounts in light of gender bias and encourage the development of female-focused perspectives.

The anthropological case study method can also yield valuable alternative perspectives on other disciplines. Ethnographic work such as Ronald Littlewood and Maurice Lipsedge's *Aliens and Alienists*, a study of the cultural biases of psychotherapy have also encouraged revisions, not only in the medical profession, but in other empirical disciplines as researchers consider the impact of social behavior and beliefs on supposedly analytical, detached studies. In business studies, the work of anthropologists such as Diana Sharpe in conducting ethnographic studies of corporations has encouraged the development of alternative perspectives on the organization to complement and develop earlier, quantitative studies along more complex lines. Agar notes that, while anthropology may have similarities to psychological analysis, the more organic, emic perspective of anthropology means that there is less reliance on labels and categorization. His research into drug addict culture helped practitioners understand the wider context of addiction rather than simply focusing on the disorders of particular individuals, thus contributing to psychoanalysis through the anthropological case study method. Finally, the activities of anthropologists have also had an impact on political situations, as they provide intellectual justifications for the political and social

claims of groups, minority or otherwise, within societies. The case study method in anthropology is thus not only integral to the discipline, but contributes to the development of other fields.

### Critical Summary

The case study method, in the form of the ethnographic study, thus is not only an integral aspect of anthropology, but, in many ways, defines and shapes anthropology as a discipline. While it has the drawbacks of needing total immersion, of problematic generalizability, and of the particular problems that relate to the deep personal involvement of researcher with subjects, it is particularly useful in situations where an impressionistic, organic mode of analysis is needed; when what is required is to know not simply what the group under study does, but how it feels to experience life from their perspectives, and also opens the doorway to the use of rhetorical devices as research tools.

## CASE STUDY RESEARCH IN BUSINESS AND MANAGEMENT

---

Case study research in business and management examines issues that are related to the industrial and economic spheres of life. Topics of interest include human interaction, events, and processes taking place in organizational, business, and company settings. Through the rich empirical description of one or several real-life cases in their proper contexts, the purpose is to produce new knowledge concerning either the case itself or theoretical constructs.

### Conceptual Overview and Discussion

Case study research in business and management can achieve various goals depending on the philosophical and disciplinary background, the goals and the research questions of the study, as well as the nature of the research design, including the number of cases to be studied. In principle, there are no limitations in terms of the underlying philosophical positions, ranging from positivism to interpretivism and constructionism, or in terms of descriptive, interpretative, exploratory, or explanatory goals. The research questions focus most often on business- and management-related phenomena, but not necessarily from the managerial or business development points of view. The point of view may also be that of the employees, customers, consumers, societal policymakers, or society in general. Practical, problem-solving, and even normative objectives can be included in the study.

Single-, multiple-, and comparative case designs are used, as well as qualitative and quantitative data from various sources (e.g., interviews, observations, statistics, minutes of meetings, annual reports, advertisements, campaign materials), and studies rely on various methods of analysis. Common features include avoiding overly simplistic research topics and designs that can be explored with quantitative research approaches, and producing detailed and holistic knowledge that is based on detailed analysis of empirical data rich in context. Because of the varied nature of case study research in business and management, there is a

tendency to consider case study research as a research strategy rather than as a research methodology or method.

Many of the classic business and management case studies rely on research designs building on one or a few cases. These draw on the ethnographic research tradition with the aim of providing a rich and detailed description and cultural understanding of business- and management-related actors, events, and processes. Single case studies may be longitudinal and historical. As an alternative to the classic case studies, Kathleen Eisenhardt has suggested that multiple and comparative case studies are valuable because they enable theory building through grounded-theory inspired analysis, which focuses on mapping common patterns and properties across several cases.

Päivi Eriksson and Anne Kovalainen, who have written specifically on qualitative research methods in business and management, describe in their book the differences between intensive and extensive case study research strategies. Intensive case study research strategy draws on the classic case study tradition, showing an interest in the case itself and developing an understanding of the workings of the case in a specific economic, social, and cultural context. Intensive case study research strategy focuses on one or a few unique cases with the aim of producing a contextualized and holistic description, interpretation, and explanation. Therefore, the explanatory power of the intensive case study research does not rely on statistical generalization but, instead, on understanding and analytic generalization.

In intensive case study research, the researcher is an interpreter who describes and constructs the case, and analyzes the empirical materials related to the case, often by focusing on the perspectives, conceptions, experiences, interactions, or sense-making processes of the people involved in the study. The case under study is rare, unusual, or extreme rather than typical. However, the exceptional nature of the case is not considered a problem, but rather a key issue of research interest. The objective is to explore and understand how the case under study works as a configurative and ideographic unit. Therefore, intensive case study research does not produce new knowledge that could be generalized to other contexts in the

conventional meaning of generalizing empirical results.

Intensive case study research strategy may be carried out with static, cross-cut research designs, but dynamic designs, looking at change or development over time, or exploring time-related issues within a case are much more common. A challenge for intensive case study research is to relate theoretical concepts to empirical investigation. First, theoretical concepts to be used in the study are not always chosen prior to empirical investigation. In other words, they can enter the study at any phase. Second, once theoretical concepts have been chosen, there is a need for an ongoing dialogue between them and the empirical data and analysis.

Extensive case study research strategy differs from the intensive strategy because of its interest in mapping common patterns, mechanisms, and properties in a chosen context for the purpose of developing, elaborating, or testing theory. The cases and their detailed description are not the main focus of interest. In this strategy, the cases serve as instruments that can be used in exploring specific business-related phenomena and in developing theoretical propositions that can be tested and generalized to other business contexts or to theory. Not all the features of the cases are necessarily analyzed in detail, as in the more intensive case research designs. The main interest lies in investigating, elaborating, and explaining a phenomenon that is often theory related, not in understanding the workings of the cases themselves. The knowledge generated from the cases can add something new to the existing theory, for instance by testing it in a specific setting or context. Alternatively, the new knowledge generated through the analysis of the cases can be used to develop new theoretical constructs.

In extensive case study research, the selection of cases usually follows the logic of replication, enabling constant comparison of the cases. In addition, the cases may serve various objectives: They validate or extend emergent theory, fill theoretical categories, provide examples of extreme types, or replicate previously selected cases. In this regard, the need for selection criteria is no different from that of any other form of experimentation based on replication logic. The selection of the cases may also be influenced by pragmatic considerations, such as access and feasibility.

## Application

Case study research in business and management is often used to investigate issues that are difficult or impossible to study with quantitative research approaches.

Two exemplars of the intensive and extensive case study research strategies in business and management are Päivi Eriksson and Keijo Räsänen's 1997 longitudinal study of the evolving constellations of product mix management in a confectionery company, and Melissa Graebner and Kathleen Eisenhardt's 2004 multiple case, inductive study of the seller's perspective of acquisitions.

Eriksson and Räsänen's historical single case study spans a 40-year period, from 1950 to 1990, with the objective of describing the long-term process of product mix management in its environmental and temporal context. The study relies on the theoretical idea of organizations as systems of interaction and influence among multiple actors, arguing that there is little systematic empirical analysis concerning how certain organizational outcomes (e.g., a product mix) are produced through the interaction of people and groups of people. The particular issue that formed the case itself was the change in product mix and the related managerial processes that concerned the interaction of constellations of manager groups in marketing, production, and general and top management. The case was selected on theoretical and methodological grounds: long history of changes in the product mix; stable ownership in a turbulent industry with an increased number of mergers and acquisitions; and excellent access, including good availability of archival data and personal interviews. Multiple data sources including personal interviews and informal discussions with managers and industry experts, price lists of confectionery products, documentary and archival data, industry statistics and information as well as media articles covering a period of 40 years provided rich empirical data, which were systematically triangulated. Interviews with the managers were a key criterion in choosing other data that were used in the study.

The study provides an example of how quantitative and qualitative data and methods can be combined in a single case study. In the first phase of the analysis, the changes in the product mix

were analyzed with quantitative time series analysis focusing on the extensiveness (the number of brands offered to the market) and renewal (the number of new brands in the product mix). In the second phase, the managerial processes were analyzed with qualitative data and methods. This included the construction of a chronological case history covering the “whole story,” combined with several event, action, and interaction histories. After the first two phases of the analysis, the concept “logic of action” was adopted to describe how each manager group developed his or her “own projects,” which relied on specific objectives, goals, means, and arguments. In the third phase, the interaction of the management groups was analyzed by looking at how each management group proposed, championed, or objected to product mix changes and how they responded to the actions of other management groups over time. This led to the identification of three different types of interaction that produced changes in the product mix: dominance, where the logic of one group dominated others; compromise, where the groups avoided extensive interaction through fear of disagreements and conflicts; and integration, where the groups interacted more frequently and developed common goals.

Graebner and Eisenhardt suggest that, despite the variety of research on acquisitions, hardly any research is done from the seller’s perspective. Their study is interested in the question: When and to whom do the leaders of entrepreneurial firms sell their companies? Because of lack of existing research, they use grounded, inductive methods and replication logic of analysis. Therefore, each of the 12 cases in their study is treated as an experiment that either confirms or disconfirms inferences that they draw from other cases of their study. The use of multiple cases is justified by the goal of achieving results that are generalizable beyond the specific cases that are studied. This is also why the selection of cases was given special attention. First, the researchers sampled four firms in three industries: networking hardware, infrastructure software, and online commerce. Further, three of the chosen case companies in each industry were acquired, but one was not. They also chose the companies on geographical grounds: 50% from the Silicon Valley, 25% from other parts of the western United States, and 25% from

the eastern half of the United States. The reason for sampling the cases in this particular way is carefully explained in the study.

The study uses several data sources and both quantitative and qualitative data including 80 semistructured interviews, e-mails and phone calls, financial data, and archival data. The first phase of data collection consisted of 15 pilot interviews with managers, investors, and intermediaries. The pilot interviews together with snowball sampling were used to identify the most influential informants concerning the acquisition process.

Data analysis started with one researcher writing individual case studies synthesizing the data from various sources, which provided triangulation in order to increase objectivity. In addition, a second researcher, who had also read the interview data, formed an independent view of the case histories, which was then incorporated into the description of each case to provide a more complete picture of the respective case. In the next phase, inductive within-case and cross-case analyses were performed. The purpose of the within-case analysis was to allow theoretical constructs to emerge from the data without any comparison of similarities and differences across cases. After the analysis of each case was completed individually, cross-case analysis was carried out in order to search for similar constructs and relationships across the 12 cases. The cross-case analysis was iterative; it resulted in a framework describing the acquisition process from the seller’s point of view. The framework describes how leaders are either “pushed” or “pulled” toward acquisition, which is characterized as a courtship between the two willing acquisition partners.

### Critical Summary

When doing case study research in the area of business and management, researchers can choose between an intensive or extensive focus, depending on the purpose and goals of their study. Neither strategy is limited to any specific kind of empirical data or method of analysis. The advantages of case studies in business and management research relate, first, to the possibilities of examining and understanding unique, rare, and atypical companies and organizations as well as complex and dynamic events and processes. Second, the advantages relate

to the possibility of generating new theoretical constructs and testing theory in a way that is more sensitive to the social, cultural, and economic context compared to quantitative research approaches. The disadvantages of case studies include applicability of the knowledge gained through the descriptive and detailed accounts of case data. The examples above offer two views of the ways in which case study research can be used to provide rich description and contextual understanding on the one hand, and theory development on the other hand.

## CASE STUDY RESEARCH IN BUSINESS ETHICS

---

Research case studies in business ethics explore the appropriateness of decisions, actions, and moral reasoning in complex situations where there often is not an obvious right or wrong answer. In contrast to case studies designed for teaching business theories, research cases are not centered on a decision maker; rather they focus on a phenomenon, decision, event, or issue that has ethical implications for how business is conducted. A

good case study allows readers to analyze the arguments and positions of key decision makers and stakeholders, as well as the contextual factors that influenced the actions and outcomes, to arrive at their own assessment of the moral implications of a situation. Business ethics case studies lead to an improved understanding of the evolution of ethical issues, comprehending the role of contextual factors in interpretations and judgments about acceptable means and ends, and refined moral reasoning as well as business practices.

### Types of Research Cases

A common foundation for a business ethics case study is a critical incident with visible outcomes, such as the Union Carbide leak in Bhopal, India; Shell's plan for disposing of the Brent Spar oil storage buoy in the North Sea; or whistle-blowing in the Space Shuttle *Challenger* disaster. The critical incidence is used to set the boundaries of the research case study, while the visible outcomes emphasize the value of the case study to both practitioners and researchers. Outcomes of these types of case studies include a better understanding of how contextual factors influence judgment, identification of needed changes to practices or policies, impact of individual or group motivation, or evolving stakeholder expectations.

In contrast to focusing on one event, longitudinal case studies track changes over time. These types of research cases are important for the identification of evolving stakeholder expectations and changing ethical standards. For example, Margaret Griesse traces how DuPont's responses to stakeholder expectations led to the transformation of an explosives and chemicals company into a life-science corporation, and how nongovernmental organizations (NGOs) and community groups shaped this evolution.

Comparative cases are appropriate for exploring potential cause and effect relationships, as well as the influence of operating practices or policies in different settings. It is also an appropriate methodology for examining why differences in judgment or decisions occur in similar settings. This design supports the identification of effective practices or policies, and can illustrate how generic practices can go awry under certain contextual factors. For example Knut Ims and Ove Jakobsen used contrasting cases

to examine the consequences of different strategic orientations to stakeholders. They compared the stakeholder strategies of two organizations developed to support the interests of vulnerable farmers, Max Havelaar for coffee growers and TINE for dairy farmers. The paradigmatic case (i.e., coffee growers) adopted a transparent cooperative strategy toward its stakeholders, while the negative case (i.e., dairy farmers) engaged in competitive tactics and collusion. The authors then compared the effectiveness of both approaches in reducing the vulnerabilities of the two groups of farmers.

Ethical issues are often the result of a ripple effect; that is, a decision or action that occurs at one level in an organization, with consequences occurring at unexpected levels in the organization or leading to unanticipated stakeholder reactions. Ripple effects are not often transparent; as a consequence, decision makers and stakeholders react on erroneous reasoning or inappropriate cause-and-effect relationships. A research case study provides the framework for exploring links across “assumed” unrelated decisions, identifying causal relationships across events, and identifying hidden consequences. One example of an adverse ripple effect is when human rights NGOs advocated for changes to children producing soccer balls in their homes in Pakistan, because the production process violated basic tenets of workers’ rights. Farzad Khan outlines the history of soccer ball production in Pakistan, the entry of the media and NGOs to uncover the exploitation of “stitching families,” the shift to factory production, and the perverse outcomes of these well-intentioned actions of NGOs.

### Design of Research Cases

The choice of setting for business ethics cases is rarely random. Criteria for choosing a specific setting or organization include occurrence of a critical incidence (e.g., employee wrongdoing, stakeholder reaction), internal practices or policies (i.e., codes of ethics, human rights issues), access to key decision makers (e.g., senior management as well as frontline employees), access to key stakeholders (e.g., members of advocacy NGOs, community members), and specific combinations of contextual factors (e.g., allegations of improper behavior, industry reputation, changing performance standards, insolvency).

Ethical problems are ambiguous and complex, with multiple stakeholders and interpretations as to appropriate actions. Thus, it is important to collect data from more than one source. Archival data include Web documents of companies and stakeholder groups (e.g., NGOs, community groups, industry associations), documents from independent groups (e.g., think tanks, international agreements), and media reports (e.g., industry publications, local and national newspapers). Concrete information about the company’s performance and policies (e.g., financial data, strategic goals, policies) is found in annual reports, policy documents, and media releases. Internal (e.g., e-mails, memos) documents provide information about informal practices and reward systems.

A common mistake in developing business ethics cases is sole dependence on information from third-party sources (e.g., newspapers, Internet) rather than from a variety of primary sources. Interviews should be the primary data source when there is a need to understand conflicting interpretations, ripple effects, or masked pressures on decision makers. Information collected in the first round of interviews directs the researcher to decision points and influential stakeholders/employees for the next round of data collection. Although interviews are a critical data source, the information obtained in them still needs to be triangulated with other data sources, such as internal company documents or annual reports.

A key benefit of case research in business ethics is the analysis of interacting contextual factors that lead to unexpected outcomes or different realities for decisions makers and stakeholders. Good judgment and expertise are based on recognizing the influence of contextual factors, and being able to anticipate in advance how they will shape realities.

Contextual factors that could influence perceptions of rightness or wrongness of an action include type of business, corporate structure, financial position, visibility of outcomes, past practices, competitors’ practices, location of operations, role of government, formal policies or practices, sophistication of community or nonprofit groups, competitive position of the company, visibility of actions and consequences, level of technical sophistication, and current issues in the media. Important contextual factors may not be immediately transparent, so researchers need to monitor

other data sources continuously to ensure all key contextual factors are eventually included in the data analysis.

Data analysis is as much an art as a science. Numerous methods can be used in analyzing ethical issues. Four methods that are particularly valuable in monitoring for converging patterns across data sources are time lines, process/flowcharts, network channels, and stakeholder maps. Time lines help identify influential factors arising from different groups or individuals as an issue evolves. Process/flowcharts are useful for analyzing internal activities or decisions, and for identifying gaps between formal policies and actual practices. Network channels and stakeholder maps are good for identifying information flows and communication patterns to identify how multiple interpretations evolved. Part of the art of good data analysis is continuous monitoring for conflicting data or indications that assumptions or the analysis needs to be refined. For example, Bent Flyvberg noted that his training in neoclassical economics led him to assume that the interactions among local businesses and city council would be controlled through competition. After many layers of data analysis he instead found collusion and secrecy among leaders of the business community and city council that paralleled situations in countries with far less developed governments. Another study examined a Spanish ceramic tile firm's implementation of an environmental management accounting system. The company had externally and internally supported the need for environmental disclosures, and justified the new system to improve its communications with key stakeholders. However, Maria Masanet-Llodra found the system was not needed, nor was it used, to communicate with external stakeholders. Rather it was implemented because of the company's strategy to be a technical leader in all aspects of the ceramic tile industry.

### Critical Summary

A well-written business ethics case provides sufficient information for a reader to reach independent conclusions as to what influenced decisions or actions, and to develop moral insight or judgment. Information on the principles followed in the research design, data collection, and analysis needs to be provided in the case or as an appendix. This

information allows the reader to ascertain the validity of the events and interpretations in the case. Including individual stories can be the most effective method for illustrating how or why differing rationalizations, interpretations, or reactions evolved. A review of appropriate moral principles or theories to clarify why specific actions or outcomes are unacceptable may also be appropriate.

As noted in the beginning, case studies contribute to the field of business ethics when they identify the evolution of moral standards, lead to new moral insight, or identify how contextual factors can lead to moral mazes. The focus of a business ethics case study should be a situation involving moral ambiguity, unexpected stakeholder reactions, or shifting moral standards. In general, these should not be based on violations of the law, unless the case illustrates problems with regulatory standards or processes.

## CASE STUDY RESEARCH IN EDUCATION

---

The use of case studies in research creates knowledge and understanding. In education research, using the case study approach not only creates knowledge and understanding but also sets a standard for good teaching practices through two main means—development and implementation of policy, and gaining experience through exposure to a particular phenomenon. Educational policies set a standard for good teaching practices that contribute to a greater overall level of education. Similarly, exposing student teachers, also known as preservice teachers, to a variety of teaching scenarios gives them the knowledge needed through experience to handle these situations effectively and appropriately if they arise during their teaching careers. Therefore, using the case study approach in education research enables an overall higher quality level of education of students.

This entry demonstrates how the case study approach is effective and beneficial as a research approach in the education field. Drawbacks to using this approach are also outlined, as well as an example of the use of case study research in inclusive education.

### Policy Development

The use of the case study approach in education research allows for the setting of a teaching standard through the creation of new policy and/or modification of existing policy. This allows policymakers to develop policy in reflection of field research. The development occurs through a variety of means, such as research into varying phenomenon, and the monitoring of policy already in practice.

### Researching Phenomena

Case study methodologies are flexible, allowing researchers to study a variety of phenomena ranging from unusual situations to complex interactions. These flexible methodologies are beneficial

in that they provide researchers with tools for capturing the different elements that contribute to peculiarities of the phenomenon under investigation. This enables researchers to expose what may have contributed to the phenomenon, and allows policymakers either to incorporate this into new policy or to modify existing policy.

In research using only quantitative survey methods, outlier cases may be disregarded as they may be seen as errors or statistically irrelevant. The case study approach differs in that these outlier situations can be studied in depth, along with the other scenarios, by targeted sampling while still having a study with statistically relevant results. In order to capture all situations, participants are chosen from specified areas. Particularly with education research it is important to study these outlier situations as they are a reality, and proper teaching policy must therefore be developed so that effective and appropriate teaching methods can be practiced. For example, although some disabilities are rare, they do occur, and in order to effectively accommodate children with these disabilities, appropriate teaching policy must be created and implemented. Without the flexibility of the case study approach, which allows for targeted sampling, it would otherwise be difficult to appropriately and effectively capture these phenomenon along with other situations in a holistic way, so that they could be studied and an appropriate policy created.

The case study approach is also flexible in that it allows for the investigation of matters that may not have been included in the researcher's original goals. Unlike quantitative surveys, with this approach researchers are not bound to a defined set of questions, but are able to prompt subjects with further questions in order to obtain more detail. This dynamic quality of the case study approach allows the researcher to expose different patterns after the interviews that may have not been initially apparent, and allows for further research in either a new or a broadened direction. Again, with this new information, policymakers can develop policy by either incorporating the information or creating new policy in order to accommodate what was discovered through the field research.

This approach is flexible in that there is a wide range of contexts the case study can cover, ranging from a single case to an entire continent. This quality is particularly beneficial in educational research

as it gives researchers the ability to be as general or as specific as is felt appropriate in order to capture adequate detail. If sufficient detail is attained in the research, conclusions may be reached, and eventually a refined policy may be developed to meet the needs of that particular scenario.

In small jurisdictions, case study research may be the only approach that makes sense. For example, in small rural school districts, if one wanted to research the available teaching services and their impact on a particular group of students, previous data might lead the researchers to adopt the case study approach. An example of this is the work undertaken by Frank Costa in 2007. Costa studied the experiences of three teenagers with traumatic brain injuries in a small school district. In this study, each teenager's experience and educational supports were analyzed and some general patterns emerged around educational supports. There were enough commonalities that some conclusions were warranted for that district. With a small sample size, the case study approach provides a logical means to complete in-depth research.

There can be challenges when trying to generalize the results from case study research, as what is observed is often contextually relevant to a particular phenomenon. The detail in the findings obtained when using the case study approach is both a strength and a challenge, but with careful analysis and supporting research, generalizations may be appropriate. For example, if a researcher wanted to look at an educational intervention in a school district, it would be appropriate to undertake a research project that has complex and varied data collection requirements, such as a case study approach. They could include focus groups, interviews, and observations and surveys of children, parents, and/or teachers. The results of such a study would apply to this school district, but the conclusions may also be of interest to other districts attempting a similar intervention. If after a few school districts attempted and researched the impact of the intervention and similar conclusions were found, wider applicability might be possible.

### *Monitoring Policy*

Sometimes policy created to solve a problem works in theory, but does not necessarily work in practice. The case study approach can be used as a

research method to monitor an already implemented policy. In educational research, the case study approach can be an effective, rigorous approach when monitoring policy, especially for teaching policy concerning children with unique needs, or classes and/or schools that have implemented a unique program.

Through this approach, researchers are given the ability to monitor these policies through a mix of various qualitative and quantitative methods, such as surveys and interviews, leading to in-depth results from multiple perspectives. Using qualitative methods, the researcher can describe the surroundings of the case. This allows insight into any potential variables that could affect the researched scenario, such as political factors, community values, and so forth. Using quantitative methods allows the researcher to report on things like instances, location, and more. Together, these methods allow for a holistic representation of the scenario. Once the variables have been identified, further research may be initiated, or if the data are sufficiently detailed and convincing, conclusions may be reached. However, if research into implemented teaching policy shows that it may be ineffective and conclusions cannot be reached, the detail provided in the research while using the case study approach may give insight as which variables may have contributed to this ineffectiveness. Policymakers can then take this scenario and its variables into consideration when developing future policy.

An important quality of effective policy to take into consideration when monitoring implemented policy is whether it can be generalized to suit the diverse needs of communities, districts, and others. As mentioned previously, one of the benefits of the case study approach is that it allows researchers to use targeted sampling so that outlier cases may be investigated alongside other scenarios. This enables researchers to conduct in-depth studies to confirm whether the implemented policy is effective throughout the entire scope of its use. For example, during the monitoring of teaching policy across a school district, subjects can be chosen from different communities within the district, including those with different cultural influences. Because of these cultural differences, the implemented policy may shown to be ineffective in some areas. Therefore, it could be concluded that the

teaching policy is not sufficiently generalized for the entire district, and action can be generated to develop the policy further, based on these results.

### *Benefits and Drawbacks*

As illustrated in the previous sections, using the case study approach in educational research has many benefits when the goal is to develop teaching policy. However, the case study approach may not always be the method best suited for a research project. Limitations do occur and one must consider these carefully before applying this approach. Having the available resources should be a major factor in the decision to proceed with a case study approach. These resources include time, funding, and experienced and/or knowledgeable researchers.

In education research, the case study approach differs from quantitative surveys in that it enables researchers to complete a comprehensive study with a smaller sample size. The smaller sample size is compensated for through targeted sampling, enabling the research results to remain statistically relevant. A smaller sample size may be beneficial in that it may allow fewer researchers to carry out the research in a shorter amount of time. However, in contrast with quantitative survey methods, the research methods involved in the case study approach may not be possible to complete remotely, and may require that methods, such as interviews and observations, be performed in person. Therefore, depending on the scope of the research, studies of education systems may, or may not, require extensive travel and time in each location. Therefore, when deciding to take this approach to research, the size of the sample must be carefully considered.

Maintaining the anonymity of the subjects involved in the case study research is of the utmost importance, and it is important to keep in mind when using this approach. This can become very difficult in some situations, especially where some of the variables that contribute to the phenomenon could potentially serve as identifying factors. Yet, as with all case study research, researchers must provide enough detail to maintain research validity. As demonstrated at the end of this discussion, this is an especially important concern in fields of research such as inclusive education.

In both of these scenarios, having researchers who are experienced and knowledgeable is useful in

that they may be more prepared to handle these situations. For example, an experienced researcher may be able to budget time effectively so that minimal resources, and therefore minimal spending, can be used while maximizing the scope of the research. An experienced researcher may also know how to develop effective procedures to ensure that enough detail is revealed in the research while maintaining minimal risk of identifying the participants.

### **Teaching Teachers With Case Studies**

Holistically described scenarios aid in allowing preservice teachers to learn about situations they may encounter in practice. This pre-exposure allows these teachers to form opinions and decide on appropriate actions, giving them the tools to handle these situations appropriately and effectively. By retelling the story, this presents a standard teaching method to follow, or how that standard may be changed to suit the needs of a particular scenario. It is also possible to present a case study to show ineffective use of policy, so that teachers may learn from previous errors and not repeat them.

### **Inclusive Education**

Inclusive education has emerged over the past few decades as an important approach to educating children with special needs. This approach emerges out of a human rights perspective, that all children deserve an education with their age appropriate peers. Inclusive education is gaining international acceptance with endorsement from the United Nations and many countries.

The challenge with researching inclusive education practices is the difference in approaches to education. For example, in the United States, inclusive education is regulated at the federal level while in Canada it is a provincial responsibility. Even at the school level, approaches to education can vary from multi-age classrooms to standardized classrooms. Each child placed in an inclusive classroom may require different approaches to education—a child with autism may require different modifications than a child with attention deficit disorder.

These complexities and realities require educational researchers to adopt a research approach

that can capture the unique aspects of each situation. Case study research is not only an ideal approach to researching inclusive education, but it can also capture the richness of data necessary to understand the multifaceted aspects of the inclusive classroom environment.

Especially vital when undertaking case study research in inclusive settings, the contextual situation must be described so that the reader can understand the situation. Multiple views must be sought to understand the interactions of players with the environment. Multiple sources of data need to be collected, including data that reflect the educational mission, such as achievement data, if appropriate. As always, especially with respect to inclusive case study research, one ethical issue that must be particularly considered is anonymity. In inclusive educational settings, the participants must be described thoroughly so that the reader understands the dynamics; yet this can be challenging to do without risking their being easily identified.

The power of case study research is that it can ask the questions of “why” and “how,” which are important in education practice. These are the questions that practitioners and policymakers need answered. As more and more case study research is conducted in inclusive education, patterns will emerge that provide researchers and educators with important results that can influence policy and practice.

Case study research can provide rich holistic data that contribute to the understanding of complex situations. Inclusive education is an example of an area that is complex, and each situation is unique with its own challenges. Case study research is a logical approach to researching many aspects of inclusive education.

### Critical Summary

Case study research has the potential to contribute to the larger field of education. It is critical that when reporting on the research, authors ensure that they pay attention to the larger context of education reform and its impact on the classroom. The case study approach is an effective method for educational research, allowing researchers to develop policy in order to set teaching standards, helping to increase the overall level of education of students. The case study approach can also be used in education research as a method of providing

teachers with experience, so that they may become knowledgeable and adequately prepared to handle a variety of situations in the classroom.

## CASE STUDY RESEARCH IN FEMINISM

---

Feminism is a doctrine, ideology, or movement that addresses and advocates for the equal rights of women. In the context of case study research, feminism is a theory *and* a research practice; a framework that can be used to examine, analyze, and critique the lives of women.

### Conceptual Overview and Discussion

Feminist research has as its objective the study of the domination and oppression of women in order to change and/or eliminate the sources of that oppression. It emerged from concerns about the invisibility and exploitation of women across several centuries. While it is often thought that feminist research focuses solely on women's experiences and issues, this is not the case. Recent feminist research conducted within the *socialist* feminist paradigm, for example, has examined men as a social category. David Collinson, Jeff Hearn, Deborah Kerfoot, David Knights, and Patricia Y. Martin, among others, have used feminist theories to examine the intersection of masculinities, management, and organizations. Feminist theories, then, can be used to study any group or situation in which one or more individuals are considered to be the "other," that is, dominated or oppressed in some manner, or who are located outside of the mainstream (as it is defined in a particular context).

Feminist research has been conducted in such diverse fields as accounting, anthropology, history, organization studies, and the sociology of workers, to study a large number of diverse phenomena. For example, feminist research has examined women entering and working in traditionally male occupations; gender and race in organizations; gendered subtexts of organizational and institutional structures; the gendering of institutions such as education; and the gendering of leadership. It should be noted, however, that not all research directed toward gender issues is conducted from a feminist perspective or uses feminist theories. Gary Powell's research on women holding management positions, for example, does not explicitly or implicitly seek to achieve social change.

### *Feminist Perspectives*

Rosemarie Putnam Tong discusses the diversity of feminist thinking in her introduction to *Feminist Thought*. She notes that the use of categories or labels in feminist thought can assist in communicating to a broader public that feminism is not monolithic and that not all feminists think alike. The labels can be used as teaching tools to mark a range of different approaches, perspectives, and frameworks that feminist scholars use to shape explanations of and propose solutions for the elimination of women's oppression. Just as there is diversity in perspectives of feminist thought, there is diversity in the names of the categories used to describe the perspectives. These labels are not intended to be definitive or mutually exclusive.

Pushkala Prasad identifies four feminist scholarly traditions: liberal, women's voice/experience, radical, and poststructural. Tong identifies eight feminist thought categories: liberal, radical, Marxist and socialist, psychoanalytic and gender, existentialist, postmodern, multicultural and global, and eco. Marta Calás and Linda Smircich discuss seven feminist approaches or theories: liberal, radical, psychoanalytic, Marxist, socialist, poststructuralist/postmodern, and third world/(post) colonialism. All of the perspectives are grounded in the recognition of male dominance in social arrangements (e.g., patriarchy and sexual division of labor) and all have a stated desire to change or eliminate this domination. Where the theories differ is in the issues they address, the questions they raise, and the vocabulary they use in the research process. Calás and Smircich note that each feminist approach provides alternative accounts for gender inequality, frames the research problems and questions differently, and proposes different courses of action to resolve identified problems. Case studies in feminism can be conducted using any of the perspectives identified here, although researchers may find some of them work better than others. Three of these perspectives are described in the following paragraphs.

### Radical Feminist Theory

This theory emerged in reaction to elements associated with male forms of power. This version of feminist theory directs its focus toward creating "woman space" through alternative institutions

and organizations. It seeks out answers to questions concerned with the exploitation and oppression of women embedded in institutional structures such as family, capitalism, bureaucracy, education, and science. Its aim is not to preserve the status quo; rather it seeks to find alternatives to patriarchy. Kate Millet, Shulamith Firestone, Mary Daly, and Marilyn French are among the feminist thinkers who are associated with the radical perspective. Case study research seeks to identify and describe feminist organizational practices that could provide alternatives to patriarchal organizational structures, processes, and practices. Many of these studies report on situations that are emotionally charged; where the ideals of equality and collective decision making collide with differences in class, race, and ethnicity, and work styles.

#### Psychoanalytic Feminist Theory

This theory is rooted in the work of Sigmund Freud. Researchers working in this tradition seek to understand the whole individual and how she relates to the world. They deviate from Freud, however, in their belief that differences between women and men are not biologically determined (i.e., differences are not present from birth). These researchers believe it is specific social arrangements such as the patriarchal family, not biology, that are responsible for distinctions in the psychological development of females and males. Psychoanalytic feminist research examines differences between women and men in a wide range of settings (e.g., work organizations, educational and religious institutions) and activities (e.g., leadership, management style). Recommendations for change are premised on the view that differences provide an advantage, not a problem, for women and that the inclusion of feminine characteristics and different approaches will improve social arrangements. Changing social arrangements, it is believed, will lead to equal gender development. Nancy Chodorow, Dorothy Dinnerstein, and Juliet Mitchell are feminist thinkers associated with psychoanalytic feminist thinking. Other feminists have critiqued the psychoanalytic perspective for further entrenching, not eliminating, gender stereotypes through its emphasis on differences.

#### Socialist Feminist Theory

This theory, which is sometimes presented in conjunction with Marxist feminism, is an amalgamation of the positive ideas and insights generated from Marxist, radical, and psychoanalytic feminism. At the same time, socialist feminism seeks to avoid or overcome the perceived limitations in each of the three theories. Marxist thought is perceived to be gender-blind, and both radical and psychoanalytic feminism are perceived to have universalization tendencies, which ignore cultural and historical circumstances. Socialist feminists, such as Iris Young and Alison Jagger, view oppression as a product of the political, social, and economic structures within which individuals live. Researchers are interested in obtaining answers to questions such as: Why does capitalism assign women to the home and men to the workplace? The research explores the embedding of gender assumptions in society's expectations and the intersection of the assumptions with rules and practices found in organizations, institutions, and society. Proposed solutions emerging from the research are usually more radical than those that seek to place women and men on equal footing within existing frameworks of processes, practices, and taken-for-granted assumptions.

#### Application

Beverly Metcalfe and Alison Linstead examined and challenged the masculinist discourse found in theories and empirical research about teams using a poststructuralist feminist perspective. In their research they analyzed the discourse of teams using textual analysis, which highlighted the implicit gendering processes present in the discourse. They then conducted a case study of an organization that was implementing a change initiative intended to increase the use of teams within the manufacturing process. They conducted in-depth, semistructured interviews with 30 individuals at various levels in the organization. The authors had a dual role in that they also had been engaged by the organization to advise on the development and implementation of the change initiative. They describe their dual role of consultant and researcher, noting that the dual roles were positively viewed by members of the organization.

They found that the theories and discourse of teams contained ambiguous power relations resulting from the construction of gendered identities and gendered relations of power in teamwork practices.

Jayne Raisborough challenged the prevailing conceptions of career as a linear progression in her case study of women Sea Cadets. Jayne was a member of the Sea Cadet Corps, which allowed her access to the research site. At the beginning of her study she found that her dual role of member and researcher was not possible to maintain because her rank in the Sea Cadets was more senior than that held by many of her potential research participants. As a result, many participants appeared cautious and guarded in answering her questions during interviews. She resigned in order to remove this obstacle, only to find that she was now viewed as an outsider and a failure by the Sea Cadets organization. Jayne describes her personal difficulties in conducting the research from a position of being both an insider with an intimate knowledge of the organization and an outsider. She notes, however, that her position provided her with a “sharper critical focus on the ways” that participation in this type of leisure activity works.

Kimberly Sultze conducted a case study of women and power using the special photography issue of the *New York Times Magazine* published in the fall of 2001. She conducted a cultural analysis of the content, drawing on feminist theories and critical frameworks. Her objective was to investigate whether or not women might be portrayed differently when photographed by women photographers. Kimberly describes her approach to analyzing the issue in considerable detail; her use of interdisciplinary research methods and her perspective that the visual images (both editorial and advertising) formed part of a larger visual culture and did not appear in isolation. She provides a list of questions that she used to guide her analysis and critique and describes her approach to analyzing both the editorial images and advertising images. Finally she provides a lengthy description of each image, its positioning on the page, and its relation to other images. Taken together, this information allows readers to gain insights into how the analysis was conducted and how the researcher arrived at her interpretations and conclusions. She found that even though women photographers had taken

the editorial images, a different point of view about women and power did not emerge. She calls for a change in the social and economic structure of media production as a means to move beyond the presentation of typical female stereotypes.

### Critical Summary

Research conducted from a feminist perspective is frequently challenged on the basis that it is politically motivated: militant and hostile to anything concerned with males and masculinity. Feminist research is a critical discourse designed to critique past and continuing patterns of male domination. Therefore it is always grounded in a political agenda. Research that does not challenge the status quo and taken-for-granted assumptions concerned with male domination is not feminist research. It is not fair, however, to presume that all feminist research or feminist researchers are opposed to men.

According to Liz Kelly, Sheila Burton, and Linda Regan, a feminist researcher has two roles in a feminist research study. She (the researcher) is part of the process of discovery and understanding, and she is responsible for creating change. In order to fulfill the first role, the researcher must insert herself into the research. Failure to fulfill these two roles can lead to poor feminist research.

The researcher’s personal social situation and personal research agenda can guide or impact the direction of the research regardless of any attempt by the researcher to remain neutral (i.e., have no effect on the research process and outcomes) and objective. The perceived absence of neutrality and objectivity has been strongly criticized by those working in the positivist scientific paradigm. It is their contention that failure to remain neutral and objective compromises the research process and calls into question the validity of the research. This critique can be overcome, however, by providing autobiographical details about the researcher and discussing the messier realities of the research process. This type of detail is normally excluded from positivist research.

A second concern that arises because of the researcher’s insertion into the research concerns power. If the researcher has power over the participants (perceived or actual), participants may behave or report events differently than in the absence of a power relationship.

The use of case study research methodology will invariably require that the researcher include interpretation leading to the question of whose interpretation is presented, the researcher's or the research participants'? Interpretation is political, contested, and unstable. It is important, therefore, that the researcher explain the basis of her interpretation. The explanations should address the decision-making process that was used by the researcher, the methodological logic on which these decisions were made, and the process of making the interpretations. For example, which empirical materials were used to arrive at a particular interpretation, were other interpretations considered and discarded, and so forth.

A final criticism relates to the presumption and presentation of the research findings as representative of or applicable to *all* women regardless of race, class, sexuality, marital status, or occupation (i.e., universalization). This critique often comes from within the feminist research community itself where it is argued, for example, that research representing the issues faced by Western, white, professional women does not speak for or represent the interests of all women.

Case studies can be used to explore and critique the domination of women by men from a variety of perspectives. Feminist theories can also be used in case studies designed to examine the domination or oppression of groups of people on the basis of race, ethnicity, and sexuality. The researcher is not limited to one particular method. In the examples presented here, researchers used a variety of methods including interviews, textual analysis, and cultural analysis to access areas of interest. There are other methods that can be used in qualitative and quantitative case studies. Researchers should select the method or methods most appropriate for their assumptions about the nature of social reality and the production of knowledge.

## CASE STUDY RESEARCH IN MEDICINE

---

The use of the case study as a research approach within medicine shares many of the features of case studies in general; however, the traditional alignment of the field of medicine with natural science approaches as well as the close relationship between case study research and the clinical practice of medicine have resulted in several distinct forms of case study research. The majority of case study research projects in medicine are premised on empiricist traditions, yet there remain two distinct approaches to the use of case study research in medicine: the first firmly anchored in the language and epistemic assumptions of a logical empiricist research paradigm, and the second, which has embraced an interpretivist orientation or an organizational analytic approach.

#### Conceptual Overview and Discussion

The case study in clinical research typically fits within an empiricist research paradigm, although

many examples of case studies exist that subscribe to interpretivist or mixed methods approaches. Research in medicine has a variety of foci, and researchers from a variety of research traditions (e.g., nursing, rehabilitation medicine) contribute to the totality of research in the field. Similarly, case study research has multiple variants within the field of medicine. In particular, case study research has been used to great effect in the study of the organizational contexts of healthcare. In their 2002 text on embedded case study, Roland Scholz and Olaf Tietje define this type of case study research as *program evaluation*.

From the literature, three distinct types of case study research in medicine emerge: (1) clinical case studies, (2) interpretive case studies, and (3) program evaluation. Both interpretive case studies and program evaluation have their origins in case study research in the social sciences, and, consequently, share the epistemological features of their progenitors. Allied health disciplines (particularly nursing) favor these types of case study research, while researchers in faculties of medicine tend toward clinical case studies as their preferred approach.

The distinguishing variable in the selection of case study type for research in medicine, according to Scholz and Tietje, is the purpose of the case study research. Program evaluation case studies are commonly employed in instances where there are concerns with and/or an interest in changing the current approach. In contrast, interpretive case study research has been employed where the object of the research is medical career issues, work-life issues, or issues of patient perceptions and experience of care. Clinical case studies are employed where the object of research is medical intervention or the diagnoses or definition of disease.

### Application

Clinical case studies have a history in medicine as a tool for both teaching and research. As an example, the neurologist Oliver Sacks has used case study to great effect for teaching and research to increase understanding of various aspects of neurological disease. A historical example of the impact of the case study is that of H. M., who underwent bilateral mesial temporal lobe resection in the early 1950s and has been the subject of multiple publications on epilepsy, memory, and temporal lobe function.

With the rise of evidence-based medicine (EBM) in the 1980s there was an increase in awareness of “best evidence” and in the development and use of tools to rate research based on levels or hierarchies of evidence. The Cochrane Collaboration is an example of an organization whose focus is on systematic review of research in healthcare, with most Cochrane reviews being of randomized control trials (RCTs). The RCT has been held up as the gold standard for research in medicine. In the language of EBM, case studies are viewed as being near the other end of the spectrum compared to RCTs and as such are defined as “weak evidence” with respect to medical research. Brian Brighton and colleagues’ discussion of the hierarchy of evidence, however, acknowledged that case studies are common in the medical research literature, and recognized their value in terms of identifying areas for research, describing rare occurrences, and building hypotheses.

### Critical Summary

In recent years there has begun a reconceptualization of “best evidence.” Robyn Bluhm, and later David Atkins, wrote about the limitations of RCTs and the value of other methods of research to further the practice of medicine. More specifically, Trisha Greenhalgh, followed by William Miller and Benjamin Crabtree, argue that there is a place for qualitative approaches in evidence-based practice.

Alan Kazdin suggested that strengths of case study research include that it is a research design clinicians can make use of without need of excessive external resources, and that it avoids the distillation of research subjects, which has the potential to decrease clinical relevance or usefulness to practitioners. Additional advantages of case study design are in pilot testing novel approaches to treatment and in situations where ethical concerns limit the use of other methodological approaches. Kazdin cautions that the challenge of case study research is to rule out alternative hypotheses that could account for the observations of the study.

According to Kazdin, a number of steps can be taken to strengthen the validity and usefulness of the case study in research. In addition to rich description, which is a hallmark of the case study, the inclusion of other forms of description that are considered more objective, such as standardized

test results, rating scales, and physiological measurements, would make comparison with the population of interest easier. Replacing a single-assessment approach with multiple or continuous assessment would also strengthen the study. Prior to treatment, multiple or continuous assessments provide a baseline from which to predict future behavior and, therefore, the validity of observed changes following treatment. The timing and degree of the effect observed are other variables that can influence the power of a case study and infer a causal relationship.

By definition, in case studies, the sample size is extremely limited (i.e.,  $n = 1$ ). From within an empiricist paradigm, this is viewed as a weakness. Kazdin suggests that case series in which several case studies with a common factor and similar response to a treatment are compiled may be a way to improve the generalizability of the observations. In addition, the heterogeneity of the subjects, beyond the factors held in common, serves to provide evidence that the effects observed are related to the common factors.

## CASE STUDY RESEARCH IN POLITICAL SCIENCE

---

Political science has no single definition or application for what is known in the discipline as a case study. What it means to do a case study—whether this should be a single case or comparative

research, done in a traditional field research fashion or in an experimental mode, informed by interpretive presuppositions or realist ones—varies across disciplinary subfields, and these issues are contested in the discipline today. There is a rich history of case study research in bureaucracy, implementation, and other public administration and public policy studies, as well as a vibrant contemporary methodological discussion within comparative studies of political systems.

### Historical Meanings and Disciplinary Organization

In part, the meaning of case study in political science draws on earlier meanings in other fields. One such is psychology, where case studies have been used since the mid-1800s to capture *details* that provide *insight into human behavior*, as well as to develop clinical *methods*. Medical cases are used in similar ways. In social work, “casework,” developed in the 1920s, entails the *detailed reporting* of a client’s history and needs as a way to support analysis for intervening through the helping process.

Another historical source is the Harvard Business School’s development in the 1950s of “cases” as a method of instruction based on *real-life contexts* to encourage *active learning*, a usage developed further at the Maxwell and the Kennedy schools. These italicized features can be found in earlier political case studies, including Peter Blau’s 1955 *The Dynamics of Bureaucracy* and Graham Allison’s 1971 *Essence of Decision*, both of which serve as classic examples of case studies that demonstrate theorizing that is situated in real-life historical and contextual details of human action. How to access or generate such data details and how to establish and evaluate their scientific standing is the focus of debate over “case study method.”

To understand the role and meaning of case study within political science today, one needs to know something of its internal disciplinary organization; and this varies by both department and country. North American political science typically has four subfields: political theory, national government (e.g., American, Canadian), comparative politics, and international relations (including security studies). Public policy and public administration, to the extent that they are still part of political science departments, are either separate or treated

as part of national government studies. In Europe, political science is commonly referred to as politics or government studies and is only occasionally divided into subfields, such as European politics, international relations, or European public administration. With the exception of political theory, all subfields draw on the case study as a method of analysis, but with different interpretations of what it means and how to do it.

Whereas textbooks describe “the case study” as the most common method of analysis in political science, these words are then used to refer to a range of meanings and usages that vary from specific methods to a research approach. Those advancing “case study” as a set of *methods*—the predominant meaning—engage the concept as a specific form of research involving multi-site studies aimed at establishing causal inferences and hypothesis testing. Those taking the second perspective typically treat “case study” as part of a broader *methodology* that emphasizes human meaning and reflexivity. These scholars more often engage in single-site research aimed at detailing the lived experiences of persons in that setting.

Despite their distinct histories and occasionally competing ontological and epistemological presuppositions, the discipline’s subfields share a widespread agreement associating case studies closely with qualitative research. This comes from the fact that case studies rest on the intense study of lived human experiences by means of on-site field work and some combination of (participant) observation, (in-depth) interviews, and/or document analysis. Each of the two perspectives described above places a different accent on case study methodology. The intra-disciplinary divide concerns the extent to which case study research is perceived as becoming more and more detached from its human-, meaning-centered origins, along with a judgment on the desirability of that detachment.

What began in the 1950s as the investigation of unique practices in sociopolitical life (the second perspective) has increasingly in the past quarter century been expected to change that approach, situating it instead in a methodological playing field that takes one understanding of natural science methods and techniques as the requirement for studies of the political to be seen as scientific. Recent textbooks formalizing case study research in political science in ways consistent with that

understanding have contributed to the development of intra-disciplinary disagreements over the character of case study research.

### Meaning-Centered Origins: Single-Site Studies

Early case studies, and many done today, consist largely of single-site studies that allow researchers to immerse themselves in the uniqueness of real-life events in what might be called a traditional Chicago School approach. The analysis is inductive and human centered and is driven by a desire to learn about the potentially multiple social realities that characterize the setting and its “actors” (or “members”). In this form, the case study is perhaps the most archetypal qualitative methodology of all, paralleling Chicago School participant observation in sociology, especially the community and occupational studies, and ethnographic study in anthropology characteristic of the 1930s through the 1960s.

The meaning-centered case study perspective is rooted in single-site studies. “Single-site” has been equated by some methodologists with single “n” studies, a point that is important for understanding contemporary disagreements about the value of case study research. Simply stated, a *single-site* study refers to research carried out in one relatively bounded setting (e.g., a governmental organization, a community), whereas a single “n” study refers to the number of observations conducted as part of experimental research. “Observation” means different things. Field research-based case studies engage in observation understood in an ethnographic sense, meaning that the number of “observations”—people spoken with, conversations conducted, events and/or interactions seen and/or participated in, documents read, and more—is not coterminous with the number of locations in which the case study is carried out.

From this perspective, a single-site case study generates a multitude of qualitative-interpretive, within-case “observations” reflecting patterns of interaction, organizational practices, social relations, routines, actions, and so on. And when “setting” is understood from an open systems perspective, the number of sites may also multiply, especially as one traces the focus of study—say, a policy being implemented—across the full range of actions entailed. Observation as treated in an

experimental sense—the source of single “n” terminology—is based on the principle that a larger number of cases subjected to analysis yields more valid general principles, another logic altogether.

In the national government subfield, for example, a case study might analyze an institution, such as the courts or political leadership. Richard Fenno’s 1978 case study of members of the U.S. Congress involved “soaking and poking,” accompanying and interviewing them as they traveled about their districts. While the single site was the Congress, Fenno investigated the tactics, perceptions, and overall political behavior of the elected representatives in multiple home sites.

Case study research has also been used for exploring local government and/or agency levels, especially within public policy and administration subfields. Herbert Kaufman’s 1960 case study of the U.S. Forest Service examined the practices of various management strategies for shaping the behavior of its far-flung employees: a single agency, but multiple geographic sites. Jeffrey Pressman and Aaron Wildavsky’s 1973 case study on the local implementation of U.S. economic development policies identified the twists and turns in multilevel decision making as the reason that agreeing on policy objectives was a lot less complicated than implementing them—another single case, here with multiple organizational and departmental settings.

These three case studies offer contextualized insights into the unique, situated practices of human political life. They represent a period in political science when “single-site” case studies were common. As qualitative researchers have come under increasing pressure, especially following the publication of Gary King, Robert Keohane, and Sidney Verba’s 1994 *Designing Social Inquiry*, to conform their research more and more to large “n” studies, they have increased their attention to theorizing about case study methodology, particularly within the subfield of comparative politics, with a noticeable recent growth in methods books and a turn toward analytic approaches aspiring to match the logic of quantitative research. This marks one of the intra-disciplinary splits between those “qualitative” researchers who accept this approach (whether they do single- or multi-sited studies) and those “interpretive” researchers who follow less realist approaches under a broader understanding of science.

### The Case Study as Controlled Research: Multi-Site Studies

Multi-site case study analysis is a hallmark of the comparative politics subfield, which has, to a large extent, laid claim to comparative case study research as its own, unique method. Like single-site case study scholars, multi-site comparativists draw upon case studies to explore human diversity, although they are perhaps more inclined to use these cases to establish general propositions about human conditions and interactions. In some instances, comparative case studies are used as a way to focus on detailed analysis of human diversity with the aim of revealing uniqueness. Theda Skocpol's 1979 comparative historical case analysis of the unique social revolutions in France, Russia, and China aimed at general theoretical understanding concerning what leads to political revolution. Robert Putnam's 1994 comparative case study of regional government in Italy analyzed the significance of civic community for thriving democratic government.

Adding "comparative" to "case study" brings additional methodological requirements concerning project design and research objectives. By identifying and distinguishing between dependent and independent variables, comparative case studies examine covariation across case data, by contrast with single-case studies done from a qualitative approach, which typically search out congruence between theory and data, looking for theory-driven within-case expectations; *and* with single-case studies done from an interpretive approach, which are more likely today to appear as ethnographic or participant observer studies and which often use case material to explore particular theoretical issues.

Comparison is treated as a "controlled" approach to research whereby the researcher is said to explore similarities and differences systematically, based on a predetermined classification of cases (e.g., J. S. Mill's method of difference or method of agreement). Research design, then, puts great emphasis on the criteria for comparability as the force driving case selection. Most qualitative comparative case study scholars make reference to small "n" comparative studies; most speak of variables, about inference and control, classification and typology.

The aim of controlled study—generalization—is advocated, on the whole, by case study scholars following positivist ontological and epistemological presuppositions and their associated methods of inquiry. This variables- and causal inference-centered approach parallels the work associated with large "n," statistics-based research. The focus on law-like generalizations that this entails runs counter to a more interpretive approach that focuses, instead, on *verstehen*, thick description, reflexivity, and other such elements for establishing the trustworthiness of the research.

Proponents of qualitative comparative case study research differ from their quantitative colleagues in that they limit the number of sites they study (fewer than six seems to be the rule of thumb), and they mix numerical and word forms of reporting in an effort to combine generalization and uniqueness. This latter idea is one advanced largely by Charles Ragin, who claims that comparative case studies not only assess general causal relationships but also have the ability to generate in-depth, contextual understanding. Looking from the outside, the methodological views of these qualitative scholars appear to be merging with quantitative researchers, both of them advancing a shared notion of science.

A 1971 article by political scientist Arend Lijphart sheds some light on these developments. Lijphart used natural science logic in assessing methods of scientific inquiry for conducting political research. He prescribed a general set of methods ranked by scientific value aimed at generalization and causation with the goal of producing scientific explanations. He listed experimentation as the first and most desirable method for scientific inquiry, followed by the statistical method, the comparative case method, and, last, the (single) case study method (which, albeit, is closely connected to the comparative method). Lijphart's hierarchy is based on the degree of control, the manifestation of time order, and the presence and strength of association, all of which are marshaled in support of causal inference. According to this ranking, a method becomes less "scientific" as it digresses from an experimental research design. This hierarchy of scientific methods and tradition of privileging methods that establish causality are carried through to today's methodological debates concerning the scope and methods of analysis that

are to characterize the political science discipline, including the place of case study among them.

### The Contemporary Scientific Environment for Political Science Research

At the moment, that form of case study research that places case studies squarely among other methods aiming for causal explanations is on the rise. This is evident in the considerable attention given to developments in and applications of techniques such as qualitative comparative analysis (QCA), optimal sequence matching, necessary condition arguments, and typological methods for analyzing cases. Textbooks single these out as advancements in case study research, on the argument that they provide a step toward a desired methodological “rigor” while safeguarding traditional case study features.

Contemporary methodologists like Andrew Bennett, Henry Brady, David Collier, Alexander George, John Gerring, and Gary King have worked to develop case study research in these ways in response to critiques concerning what these researchers have perceived as the limitations of more meaning-focused, traditional forms of case studies. While these developments encourage reflection on the character of the method, the changes reflect a narrow understanding of science that rests on such terminology as selection bias, (internal) validity, reliability, and generalization.

A technical, detached, and often complex language recurs in the wealth of case study textbook chapters dedicated to presenting methodological safeguards for case study research. Entire chapters engage such procedures as “process-tracing” (within-case analysis to track links between likely causes and outcomes), “typological theorizing” (contingent generalizations based on systematic comparison and case selection), and “path dependency” (time reference used to explain causes and choices). All of these are intended to refute challenges to internal validity and selection bias attributed to case study research. This language assumes ontological and epistemological presuppositions associated with positivist and sometimes critical realist philosophies, at the expense of engaging with case study methods informed by interpretive philosophical presuppositions that would emphasize such criteria as thickly described narratives of

situated lived experience, research positionality and reflexivity, and the multiple possible meanings of political language, acts, and physical artifacts.

These trends might be understood as a commitment to ensuring a competitive position for case study research in contemporary political science by updating earlier case study notions with newer, more effective tools. Alternatively, the trends could be interpreted as a defensive posture—the aftermath of a lingering 1963 remark by Donald Campbell and Julian Stanley about how single case studies had *no* scientific value. The King, Keohane, and Verba advocacy of a single approach to scientific inference for both the natural and the social sciences might also be understood to play a role. Either interpretation is indicative of a decisive turn toward the systemization of case study procedures in a particular direction, and this is portrayed in textbooks as a way forward for qualitative case study scholars.

### Evaluating Case Studies and Concepts

Many of the aforementioned contemporary case study scholars explicitly promote combining quantitative and qualitative methods and devote considerable attention to issues of design as a way of ensuring scientific rigor. Their methodological writings focus on orderly, systemized, and verifiable case study procedures. Case study’s use for a more interpretive understanding of social and human life is increasingly less visible. While it is still possible to find some references to the advantages of case study research for offering real-life insight into social phenomena, flexibility of methods, and sensible translations of theory, as in Bent Flyvbjerg’s 2001 work, it is by far more common to find references to its (newfound) potential for testing hypotheses, examining causal mechanisms in detail, assessing the reliability of inferences, or developing internally valid measures of concepts.

A fair amount of discussion, especially in comparative politics, has focused on concept formation and definition and the extent to which the operationalization of concepts needs to be grounded in the case study at hand. This point lies at the heart of the differences between qualitative and interpretive case study research design and methods. The debate concerns a priori versus situated concept formation; that is, the stipulation of

concept meanings that are defined prior to the research versus “meanings-in-use” that are allowed to emerge during field work in the course of the research. A priori concept formation is prominent in comparative or multi-site case study research and goes hand in hand with a “controlled” case study research design. The argument for such an approach is that even though concepts may have different meanings in use, this is a matter of degrees of difference rather than differences in type of concept, making comparison possible.

Other scholars argue that conceptual meanings cannot be fixed in the abstract, that they are highly contextualized. In such an approach, the uses of terms and definitions are linked to unique experiences and embedded in time and space; influenced by linguistic, country and/or regional, organizational, and/or communal history and situation. The argument emphasizes the need to understand concepts as rooted each in its own particular setting. Frederic Schaffer’s 1998 *Democracy in Translation*, studying the meaning of “democracy” to the people of Senegal, is an example.

The general claim that case study research is a qualitative method remains, but scholars differ on the meaning of this label in the argumentation for case study research.

### Critical Summary

Case study research remains a central method of analysis in contemporary political science research, despite periods of more and less acceptance and the rupture between those who wish to preserve its earlier form and those trying to bring it closer to quantitative modes. Growing attention to methods and methodology in the context of particular meanings of “science” is also reflected in the textbooks. Until fairly recently, case study methods textbooks were rare and, for a while, Robert Yin’s 1984 text (in various editions) was the only one available. It was an influential piece, but it has taken case study’s traditionally more interpretive focus in realist, positivist directions.

A large part of today’s methodological treatments of case study research in political science comes from comparative politics scholars, and that subfield is currently providing significant impetus in the direction of multi-sited, comparative case

study research. Those methodologists are making every effort to articulate what comprises a case study in order to increase its acceptance in a wider, largely quantitatively oriented methodological playing field. More and more, case studies are being described as ranging between little detail across many cases and a lot of detail for a few or a single case. Prior notions of meaning-giving inquiry are either being bypassed or overshadowed by specific terms and methods that ignore interpretive inquiry in favor of attention to variables-based causal inferences.

While it is difficult to anticipate the future of case study research in political science, it can be said that much depends on how present methodological debates unfold and how intensely political scientists hold on to earlier forms of case study research as a legitimate way of doing science.

## CASE STUDY RESEARCH IN PSYCHOLOGY

---

Case studies in psychology reconstruct a major episode in people's lives by identifying a particular set of problematic or otherwise interesting events and relationships that naturally occurred in the real world. They can be studied or understood only in their context as they merge with their environment, so it is difficult to draw precise boundaries. The analysis and interpretation of case studies is most often intended to lead to a better understanding of the area of inquiry; that is, deriving or testing theories. Depending on the branch of psychology that uses case study, not only individual processes and possible solutions to their problems may be the focus but also processes within groups, institutions, or communities. Psychological case studies can have many forms, such as narrative accounts, detailed technical or judicial reports, documentary films, or sets of observations.

### Conceptual Overview and Discussion

Psychological case studies focus on individuals, though different interpretations are possible that include context or time dimensions. They frequently share characteristics with case studies in other disciplines within social sciences whose focal points are description and analysis of contextual factors, social structures, and processes in order to reach a more global understanding of events.

Most psychological case studies are retrospective in style and follow an idiographic approach wherein both qualitative and quantitative proceedings are feasible. Apart from a description of the events that are to be examined, psychological case studies most often include a causal analysis of central problems, and sometimes also recommendations for courses of action based on the analysis.

Wilensky's 1983 study proposes a general theory of psychological case studies that helps to assess whether a case study is a psychological one, and to judge its quality as well. According to him, a psychological case study consists of a person,

specified by the formula "identity + description"; a situation, characterized by "constraints + opportunities + contingencies"; and a related outcome, being "changes in person + changes in situation."

In differentiation from life histories that consist of a series of case studies about one person, psychological case studies address only a particular pattern of behavior in a particular set of circumstances over a limited period of time.

### History

Psychological case studies are of relatively recent origin and have their sources in psychiatry and social work; they have been used as a research method since the early part of the 20th century. These early psychological case studies were modeled on medical methods; that is, they often contained short clinical case vignettes or brief reports on personality description and social relationships.

After World War II, experimental and psychometric approaches became dominant and displaced case study research to clinical psychology and personality studies. Due to this development, the scientific character of case studies has never been explored thoroughly, and case studies are often neglected in textbooks except for some contributions on the specialized single-case experimental method. Therefore, there is no general agreement on the organization, content, or employment of case studies in psychology. Often they are conducted for practical purposes and their theoretical aspects are neglected. Over the past 15 years a major growth of nonexperimental case study research can be observed within ecological psychology, a branch that is studying humans' interactions with their environment.

### Methodology

In psychology, several different methodological approaches can be found. The positivist style is interested in developing a generalizable theory or laws from evidence by deductive procedures: that is, studying literature, working out which theories might be adequate, and setting up experiments to gather new data to test the theory.

Researchers who follow a naturalistic approach cannot be sure that existing theories are relevant for the case under investigation as human behavior

is unique and specific; thus generalizations are difficult to make. Therefore they prefer an emergent design, that is, creating theories inductively and intending to make sense of the data they found only after they have found them. They are on the lookout for qualitative elements that lie behind more objective evidence, such as how people understand themselves or their setting. They do not ignore objective data—for example, staff turnover—but search for underlying reasons in the process, thus examining people's emotions, perceptions, and experiences of what is going on.

Researchers of both traditions have to be aware of the fact that research investigation is never neutral as there will be effects on individuals or organizations just because there is someone who is asking questions or observing people.

Closely linked to the differentiation between positivist and naturalistic approaches are ideographic and nomothetic traditions within psychology. Researchers who work with case studies often come from an ideographic tradition, that is, their goal is to understand how this very person or event developed the way it did. The goal is not to confirm or expand experiences to form any law about people in general, but to focus on the particular and individual to understand meanings. According to ideographic tradition, nomothetic appendages deal with group averages and not with particular cases, whereby no information about individuals can be drawn from group data. Statistical data tend to suggest there would be a “modal individual,” but in fact these data are indeterministic and construct people that in reality do not exist.

Case studies are not only explorative in their nature, they are rather much more realistic than other designs as they are closer to data. They allow reference to similarities between different persons although these persons are dissimilar at first sight, and vice versa. They may also point to factors that would have been neglected in a larger group study or reveal flaws in theoretical conceptions and give hints for how theories may be revised. Their aim is to demonstrate existence, and not incidence, of a particular feature.

Nevertheless, quantitative data, that is, descriptive or summarizing numerical data and inferential statistics such as correlations, may play a role in case study research. Records on seasonal effects, trends, sex, and age differences, for instance, may

be useful supplements as they allow cross-checking with other data and increasing the internal validity of a case study.

It is furthermore important to differentiate between extensive and intensive research designs. The former means specifying all members of a class to define that class; the latter implies indicating the properties something needs to be a member of that class. Intensive designs therefore take one single case, presume certain properties of the class on a trial basis, and try to construct an extension. Psychology most often tends to prefer extensive designs, though they are not suitable for many psychological questions.

Some psychologists work with case studies that aim at establishing case laws (i.e., laws that are each generated for a specific case and then can be combined to formulate a more general law) by analytic induction, a procedure that is well known in sociology. This procedure shows that ideographic procedure and a search for nomothetic laws are not necessarily contradictory, and combinations between them do exist.

First, one has to generate a tentative hypothetical explanation about an interesting phenomenon, then take a single case and test by qualitative or numerical methods (e.g., cluster analysis) as to how far the explanation fits. If necessary, the hypothesis is modified to make it fit the case. The modified explanation is then tested with the next single case and the hypothesis is revised. This process is continued through a number of cases. Cases are thereby not selected based on usual demographic sampling considerations, as the interest is to describe and analyze categories of human behavior or types of persons.

By employing this iterative procedure, the final resulting hypothesis has much stronger explanatory power. It is also possible to search for negative cases to disconfirm one's hypothesis and thus make the proposed hypothesis as critical as possible. A successful hypothesis, then, is true for most of the cases tested, because a final hypothesis that is true of all cases is impossible in practice. The produced explanation is as provisional as every other scientific explanation, independent of the procedure that had been followed.

The result of a single case study is insufficient to confirm a universal hypothesis; it can only reject a hypothesis. However, it does not necessarily falsify

the entire universal hypothesis, instead it debilitates the hypothesis that was formulated and examined in the context of specific constraints. A rejection of a hypothesis is not the death of the theory. It indicates, in fact, that additional assumptions are to be made; that is, the failure of the theory may be due to factors other than the theory itself, such as wrong implicit assumptions.

### Application

Case studies are found in many different areas of psychology, ranging from clinical psychology to neuropsychology, and from complex problem-solving to cross-cultural psychology. Their use is likewise varied. It may range from case studies being used in a clinical context as analysis of a person's case in the form of a single case analysis or comparative case studies, or as a basis for the development of simulation games in the domain of complex problem solving. People themselves may work on specific case information, or the investigators may analyze the case. The number of cases under analysis may range from intensive study of few cases to less intensive study of many cases.

Case studies are usually used in combination with other methods, such as participant observation or questionnaires, sometimes together with sources that provide quantifiable data (triangulation). Case studies may be used for exploratory reasons, but they also allow for gradual development of a case law as several single cases are written up and considered in relation to each other. They then may provide valid and reliable results that are grounded in data and can be replicated or confirmed by employing further methods. Apart from use in research contexts, they may also be used for teaching and training purposes, such as situational analysis, decision making, theory construction, or simply as illustrations for theoretical explanations.

When developing a case study, multiple forms of evidence should be collected and studied in sufficient detail. Analogous to what the social anthropologist Clifford Geertz said about research into culture, research into any person or organization has to begin with describing in detail what one has found—"thick description"—thereby paying attention to the fine-grained details and pondering them. After getting to know the case in its setting

and reading literature that may be of relevance, one can decide about broad aims and formulate one's research questions. Evidence may come along in the form of documents, records, interviews, detached or nonparticipant observation, participant observation, or physical artifacts. It is considered useful to maintain a research log containing notes on evidence, as well as personal notes such as insights or questions to cope with complexity and to document the process of one's own reasoning.

### Critical Summary

#### *Advantages*

Psychological case studies contribute several benefits. First, they provide a rich data base and procure process information. The researcher can thereby gain a detailed picture of individual processes and reveal important individual differences between several cases. Using case law methodology and following a bottom-up principle, conclusions from particular cases can be drawn to types of cases. Adding further cases may lead to a deeper understanding of events and refine the conceptual framework until additional cases no longer add new information.

Furthermore, case studies prevent simplifying matters too much. They do not take into account only broad structural or demographic variables but allow for reconstructing the complex causal structure that lies behind an event and that can be examined from an insider's view, that is, the involved persons, as well as from the external point of view of the researcher.

#### *Problems*

Some reservations against case studies should also be mentioned. Scientists claim that investigators may distort results in that their descriptions and analyses are not exhaustive but selective and subjective or, as the researcher defines the issue, arbitrary. Furthermore, premature generalizations may occur and circularity may be caused when testing and developing a theory within the same set of data. Apart from that, it is argued that case studies help only in defining a problem and often lack an explication of boundary conditions when hypotheses are examined.

### Standards

A well-defined case study should reduce subjective factors to a minimum, for instance by incorporating several independent sources. Besides, evidence and inference are to be separated and reasons for conclusions should be given. Furthermore, investigators should make sure that original data can be reexamined, and should take boundary conditions into account when analyzing a case. Whether one works with case studies or not should not be a matter of ideology but depend on the purpose one pursues. Therefore the question is, when might case studies be used in psychological research and when not. Case studies are rather valuable when researchers are interested in process information. They are also appropriate when hypotheses are investigated that make direct statements about individuals, but not when the hypotheses refer to classes of subjects or fictitious statistical modal individuals. Single case studies may also be beneficial for guiding decisions about which experimental factors could be important for group studies, thus taking on a filtering function.

For instance, when studying complex problem solving by working with computer simulations, group designs are more or less useless as it is difficult to control experimental factors precisely. Different individuals will develop rather different representations of the task; thus investigators have to deal with heterogeneous internal representations that may change over the course of time. In group studies, such process information would be ignored. In this case it would make sense to follow a case law approach, thus studying various single cases and deriving hypotheses about dependencies and determinants of problem-solving processes that then can be implemented in a computer program that generates synthetic behavior. This can subsequently be compared with empirical performance and finally lead to an adaptation of the underlying model in the event of deviation.

## CASE STUDY RESEARCH IN PUBLIC POLICY

---

Case study research in public policy is a qualitative research method that is used to enhance our understanding of the policy-making process. By using case studies, one can learn how public policy is designed and implemented. Public policy case studies provide insight not only into decision-making processes, but also into the political and organizational environments from which public policy emerges. Through the use of public policy case studies, one is able to test case study research data against a range of decision-making theories and models. Public policy case study research can be used as a pedagogical tool as well as a form of applied research.

### Conceptual Overview and Discussion

Definitions of public policy usually begin with Thomas Dye's observation that public policy is based upon governments choosing to take action or not to take action. Based upon this definition, public policy is a general concept that can be applied to a wide variety of government activities and behaviors. Public policy is generally associated with the actions of government. Governments have two basic functions—to regulate and to provide programs and services. Regulations emanate from executive and legislative authorities. That authority is legally vested in public agencies or professional bodies. The policy impact of public agencies on our lives is so overwhelming that many citizens simply accept much of that authority as a natural part of their existence. Usually it is not

until things go wrong, such as the recall of tainted food, the discovery of unsafe drinking water, the importation of toys with lead paint, or a deregulation-driven institutional financial crisis, that citizens become aware of and demand immediate action from public authorities. Government regulations extend beyond the domestic sphere into the field of international relations, covering such matters as foreign policy, international financial and security agreements, trade delegations, and multi-governmental organizations.

The provision of public programs and services is largely dependent upon the ability of governments to fund such services. Public programs and services cover such large fields as healthcare, education, social services, labor, justice and policing, national defense and state security, agriculture, fisheries, the environment, immigration, and public works.

Public policy research focuses on trying to observe, as much as possible, what is going on within these large fields. The resultant studies provide rich, often minute detail on the real-world policy actions of public authorities. Those observable actions can take place at the international, national, regional, and local levels of government. Public policy research has grown significantly over a relatively short period of time. The public's thirst for knowledge and a better understanding of the policy-making process has grown in the era of e-government, because of easier access to information and continued demands for greater transparency on how public dollars are spent. Government departments and agencies are also being pressed to state policy priorities clearly and to provide accompanying documentation in order to explain various roles, responsibilities, and organizational accountability in the policy development process.

Public policy and public administration, another major subfield of political science, are concerned with the theory and practice of government. Case study research in public policy is an important analytical tool that can illuminate the actions of various policy actors in attempting to influence the policy-making process. Illuminating policy influencing factors allows for the interplay between formal presentations of public policy decision-making theory and actual practice. Moreover, case study research in public policy attempts to bridge the gap between the academic world of rational-normative approaches as to how public policy

should be made and the imperfect, real world of policy making. The difficulty in developing theoretical explanations for public policy outcomes sometimes arises from the view that government officials often "bill themselves" as avowedly pragmatic when it comes to the policy decision-making process.

### *Theoretical Models and Perspectives*

There is, however, no shortage of prescriptive theoretical models and perspectives that offer analytical and descriptive explanations as to the how and why governments, managers, and public servants act the way they do. Some deterministic theoretical models such as Marxism explore the structural limitations of what policy actors can and cannot do. Dynamic theories such as pluralism and public choice emphasize the open-ended, competitive nature of democratic political systems. Then there are the theoretical models that focus more specifically on individual and group organizational actors in the policy decision-making process. Understanding the basis for what governments will or will not do is at its most difficult stage when academic public policy and public administration writers attempt to provide theoretical explanations for various policy outcomes.

Theoretical models that focus on organizational actors help public policy and public administration researchers understand the complexity of the policy development process from a number of different viewpoints.

There are three theoretical models that commonly appear in the introductory literature on public policy. These models compete with, but are also complementary to, one another. The first model is called rationalism or the rational-comprehensive model. Rationalism, as the term would imply, is a normative and a descriptive model that speaks to how governments should thoroughly plan and critically analyze each policy decision, in terms of clearly stated objectives, goals, and outcomes. Once decisions are taken, the subsequent program activity associated with the policy decision must be evaluated and analyzed. James R. Anderson developed the "rational" model because of the importance he placed on the need for management to have as much information as possible in order to develop department-wide

planning fully, or what we might refer to today as a horizontal approach.

The second model is called incrementalism. Incrementalism is sometimes referred to as the muddling-through approach because of the model's analysis of the conservative nature of government public policy decision making. Charles Lindbloom argues that the incrementalist model most closely approximates the real world of policy making as government policymakers closely follow traditional organizational methods and practices when they address current problems. Any changes to the application of those methods and practices are usually done on an incremental basis. Lindbloom eschews the grand planning exercises associated with the rational model in favor of decision-making processes that are easy to comprehend and implement, as policymakers often do not have the time, the resources, or the kind of information that would be required for more elaborate exercises. A third model, mixed scanning, combines the rational and incrementalist models through the work of Amitai Etzioni. He argued that while public policy-makers will make incremental changes most of the time, fundamental changes will also occur based on a rationalist approach to significant policy challenges. Governments choose the incrementalist or rationalist approach based on policy research obtained through scanning their environment.

Each of the three prescriptive theoretical models of decision making seems quite plausible, and advocates will strongly expound the respective theoretical merits of their model based upon case studies.

### Application

A typical public policy case study is composed of an abstract, a case introduction, case instructions of what kind of action is required of the participants, accompanying documentation, and some possible options for consideration. Through interaction with a public policy case study, learners are able to explore different competing viewpoints, develop their own decision-making process, and explore the potential consequences of their decisions. They also learn that no policy decision is perfect, given the atmosphere from which public policy develops. Public policy case studies do have

an advantage, based upon the political nature of the subject matter, of being able to tell a good story. Eliciting interest on the part of the learner is an important aspect of any pedagogical tool.

Case study research in public policy has become an important learning tool in graduate programs in public policy, public health, public administration, and business administration. The cases are used to provide learners with an understanding of the public policy process in terms of how government creates, develops, and implements public policy. The Kennedy School of Government, Harvard University, is, according to its Web site, the world's largest producer and repository of case studies designed for teaching how government works, how public policy is made, and how non-profit organizations operate. A wide range of case study topics is grouped alphabetically under a range of categories.

The Institute of Public Administration of Canada (IPAC) has a case program in public administration that has produced 160 cases in a variety of areas. IPAC case studies are developed by public servants, academics, and students in order to provide insight into the public policy decision-making process. Case topic areas include administrative ethics, financial prioritizing, health-related policy decisions, what to include in important communications documents, labor relations issues, managing environmental disasters, intergovernmental negotiations, dealing with scandals, workplace discrimination, and how senior public servants deal with an ongoing issue.

Perhaps the most famous case study in public policy is *Essence of Decision: Explaining the Cuban Missile Crisis* by Graham T. Allison. According to Robert Yin, this formative single case study of policy decision making functions as both an explanatory case study and a descriptive case study. The case study focuses on crisis management decision making at the executive government level, with participants looking to advance the interests of their own organizational units. The policy decisions that were ultimately taken substantiate Allison's famous dictum that where you stand may largely depend upon where you sit. By examining the motivations of various policymakers, analytical insight was developed into how and why certain decisions were taken by the White House. An atmosphere of crisis management existed at that

time because precipitous action might have led to a nuclear confrontation between the United States and the Soviet Union. After a detailed exploration of the policy decision-making process, Allison put forth and analyzed the “rational actor,” “organizational process,” and “governmental politics” theories as possible explanatory models for the strategic decisions that were taken by both sides in the period leading up to and including the Cuban missile crisis. The descriptive and explanatory power of Allison’s case study has led to continuous debate regarding the lessons and theoretical models associated with the single case study. Yin points out that the explanatory power of that case study has caused researchers to generalize beyond the political case narrative into a wide range of government policy activities. A second, coauthored edition of the case study was released in 1999. This edition took declassified government documents and recordings into account as well as updated interviews with the then-current senior public officials. The result was that some theoretical positions were substantiated because of the new materials while other theoretical positions were put into question.

Designing case study research in public policy involves planning, conceptualization, analysis, and communication. According to Ann Majchrzak, some of the most important activities in the policy research process will occur during the initial planning period. In order to focus on a potential public policy topic, a researcher needs to build up a level of knowledge so that the feasibility of a potential study can be determined and the purpose of such a study can be established. A comprehensive literature review will allow the researcher to build up that level of knowledge. From there, a set of initial research questions based upon a tentative theory or model can be developed. Case selection follows. Will a single case or multiple cases be chosen? There is certainly no shortage of potential public policy cases to choose from. The selection of the case study should be based on the purpose of the study. That brings us to the data collection stage. While the case study is a qualitative research method, quantitative data can be an important component of the case.

A number of methodological collection tools are used for data gathering purposes. Public policy case studies are built on documentation and different levels of government, national and international

nongovernmental organizations, policy networks, think tanks, interest groups, university research centers, and political parties provide a wealth of information that is waiting to be mined. Making decisions about what to study in connection with the policy topic is important because it is easy to become overwhelmed by the amount of data that is available. Existing public opinion survey results can provide some quantitative data, even if these are in the form of quasi-statistics. Perhaps the most interesting data collection tool in public policy case research is interviews with key informants. The key informants may be leading policymakers who could provide valuable background information leading up to a policy decision. They could also be the public servants who have been charged with implementing the policy. Or they could be managers who are trying to develop the policy while feeling the pressure coming from the top and the bottom of the organization. Relevant stakeholders, such as program recipients, may also provide valuable data. Some of the initial interviews may not be for direct attribution purposes but rather to allow researchers to gather background information from informants, who can be quite candid if they do not have to go “on the record.”

Developing different perspectives from various sources for a public policy case study is a key to understanding the complexity of the policy process and why public policy emerges in a particular way. Gaining access to key informants may require considerable lead time and that is why the initial planning aspects leading to the choice of the policy topic and case selection cannot be underestimated.

Once the data have been collected, databases can be developed in order to sort through the material for analysis. Case study analysis in public policy typically involves using quantitative data as support for the qualitative data, which allows the researcher to drill down in order to derive meaning from a number of the relationships that underpin policy, from which public policy emerges. Once the analysis is complete, the case study narrative can be developed in concert with the data.

### Critical Summary

Public policy case studies provide the reader with a detailed description of a situation that requires a decision or sets of decisions from policy actors.

The decision or set of decisions is then analyzed to identify the constraints, approaches, and techniques that are part of the policy decision-making process. The roles of the policy actors are also explored in detail. There is often, however, considerable debate over the legitimacy of theoretical models that have been developed on the basis of the cases studies. The legitimacy of public policy theoretical models is sometimes called into question because of the ideological perspectives that underpin case study design. Such ideological perspectives are to be expected, however, because public policy emerges from government and politics, and that is what makes public policy research so interesting to many researchers.

## CASE STUDY RESEARCH IN TOURISM

---

A multidisciplinary field in social sciences, tourism research, has formed a unique intellectual community for the practicing of case studies. Case study research in tourism involves empirical

investigations of what Robert Yin called a contemporary phenomenon within its real-life occurrences, in which the boundaries between the phenomenon and its context are not clearly evident and where multiple sources of evidence are required to explore, describe, or explain the real-life situation. The use of case studies, the developmental nature of this method, and its epistemic position in tourism research are reflected through critical appraisals of this approach in the ever-expanding body of tourism knowledge.

### Conceptual Overview and Discussion

As in other social sciences fields, case studies in tourism have mistakenly been regarded as a weak approach to the generation of social scientific knowledge; that tourism knowledge has been generally characterized by case studies, area-specific discussions, best practice examples, and one-off or one-time research. Consequently, tourism research is perceived as stale, tired, repetitive, and lifeless. The trouble with its theoretical state of the art is attributed to the fact that its researchers keep producing an enormous record of case studies in response to the staggering expansion and variation of the tourism industries. Reflections on its methodological state of the art suggest that tourism researchers turn to alternative or innovative strategies rather than continue to produce more and more case studies of limited scientific value. These perceptions of case studies as atheoretical, area-specific, one-time, and not following methodological procedures, which were historically well-entrenched in a number of social science disciplines, are extended to the relatively new multidisciplinary community of tourism research.

Nonetheless, case studies have long been a topic of interest in the methodological literature. In a critique on the sustained interest in this method, Jennifer Platt suggested that case study as a research strategy has grown out of the methodological traditions of both qualitative and quantitative inquiries such as the grounded theory and the logic of experimental designs. Robert Stake referred to its vantage as the study of the particular, which encompasses the nature, historical backgrounds, physical settings, as well as sociocultural contexts of a specific case. Jean Hartley succinctly noted that case studies allow for processual, contextual, and longitudinal

analyses of various actions and meanings in organizational research. In a critical reflection of its use in social sciences research, Randy Stoecker stated that the case study approach has been wrongly maligned as it is the best way to refine general theories and apply effective interventions in complex situations.

In terms of research design, Harry Eckstein categorized the variations of this approach into configurative-idiographic studies, disciplined-configurative studies, heuristic case studies, plausibility probes, and crucial-case studies. Robert Yin, on the other hand, used a refined typology of exploratory, descriptive, and explanatory case studies, to be developed in the maximization of construct validity, internal and external validity, and reliability. Each of these typologies is seen as an effective tool in contexts or situations that are often too complex for experimental or quasi-experimental designs. In addition, case study is differentiated from history or historiography in that the latter involves special ways of verifying documents and artifacts in dealing with noncontemporary events when techniques such as participant observations, direct measurements, or interviews cannot be used as corroboratory evidence.

With respect to implementation, data analysis, and theory building, methodologists have outlined a series of procedures that can be employed in a variety of contexts. These include tasks such as the training or skill preparation of investigators, the development of protocols, the conduct of pilot case studies, and the actual implementation of a case study research plan. Such steps are suggested in order for case study data collection, usually from multiple sources and by various means, to triangulate on the “fact” or the set of prespecified research questions.

In data analysis, Yin proposed strategies such as relying on theoretical propositions, setting up frameworks based on rival explanations, and developing case study descriptions, for the construction of theories. In a state-of-the-art account of building theories from case study research, Eisenhardt developed a systematic process with a series of steps to watch for while doing analysis. The opportunity to explore issues in depth and in their contexts means that theory development can occur through the systematic piecing together of detailed evidence to generate (or perhaps replicate)

theories of general interest. Eisenhardt summarized the strengths of this approach in terms of its likelihood in generating novel theories, its testability of emergent theories or hypotheses, and its likelihood of empirical validation of resultant theories.

With the increase of interest in, and consequently an increase of literature on, case study methodology, stereotypical perceptions have been changing over the years. In light of an ascending incorporation of ontological and epistemic considerations in its design logic, Jacques Hamel concluded this approach embodies undoubted theoretical and methodological qualities. The thick description characteristic of case studies allows for a move from one epistemic form to another. In this sense, Hamel alluded to the case study method as a cornerstone of new theoretical and methodological strategies for sociology. As a result of its widespread use, methodological appraisals on its applications can be found in a variety of social sciences fields, including tourism research.

### Application

Case study is a widely used strategy in tourism research. Honggen Xiao and Stephen Smith, in a content analysis of case studies published in tourism journals, alluded to the methodological state of the art of this approach in the tourism field, which can be summarized from a number of perspectives. First, in terms of thematic or topical coverage, case studies in tourism research are used in contexts or situations as diverse as planning and development, community perceptions of tourism impacts, alternative forms of tourist experience, decision-/policy making, career development and professional training, destination marketing and image, segmentation and tourist markets, cultural and heritage tourism, host-guest relationships, organizational operations and dynamics, service provisions and service industry management, and festivals and events.

This method is also found in designs to fulfill case-/place-specific purposes in terms of a study's stated objectives or research questions, which are directly related to a site, organization, or locality under scrutiny. Site-/place-specificities of a tourism case study are sometimes attributable to factors such as the nature of research, its funding bodies, and the varying degree of elaborations characterized by different authors or for different purposes.

Second, authorship attributes suggest that case studies in tourism are conducted by a multidisciplinary team of researchers from a variety of departments/faculties such as tourism, hospitality or hotel management, recreation and leisure studies, economics, business, marketing and management, geography and environmental studies, sociology and anthropology, education, information technology, and public administration. Moreover, case studies in tourism often appeared as coauthored or joint research, which could be a reflection of the extensive time or prolonged efforts needed for conducting such inquiries.

Third, with respect to geographical scales, time points of observations (or time specificity), and the number of cases used in the research design, case studies in tourism often fall into either a small or a large geographical scale; for example, an attraction site or a destination country. Tourism organizations or agencies, hotel chains, airlines, and tour operators are also frequently used as case study sites; in such instances, the coverage and diversity of their businesses often add to the complication for the implementation and data collection of a case study. Due to the centrality of space and place in tourism, case studies in this field typically tend to have a geographical focus.

In terms of the time points researchers use for data collection, case studies in tourism are found to have frequently adopted one-time or cross-sectional approaches. A small number of instances can be regarded as longitudinal in their utilization of two or multiple time points for observation or data collection. The frequent use of one time point in data collection is attributable to any of a number of reasons prevalent in the tourism research community, including budget constraints, report deadlines, or the researcher's choice of paradigms as in the case of an ethnographer's need for a prolonged engagement with a study site versus a quicker, one-time survey. Although some undertakings adopted two/comparative or multiple-case designs, most case studies in tourism follow a single-case design.

Fourth, in terms of data collection, triangulation through multiple sources of evidence is often seen in tourism case studies. Specifically, secondary data (e.g., archival/statistical documents, government reports, and news articles) and surveys were used most often, followed by interviews and focus

groups. Participant or on-site observations were less frequently seen in tourism case studies. By virtue of the estimated length devoted to the description of method and data collection, a majority of tourism case studies bore a limited-to-moderate description of methodological procedures.

In terms of analysis and presentation, about half of these case studies were quantitative reports with statistical tables, figures, and occasionally economic equations or formulas. About one third of such reports are distinctly qualitative, which is often characterized by thick descriptions, historical accounts, or ethnographic narratives, with information-rich texts or extensive quotes from key informant interviews. About one out of 10 case studies used a mixed approach in the report writing. Similarly, by virtue of the length used for the discussions of research findings, the case study approach, seen from this content analysis of tourism journals, has moderate-to-high potential for contributing to knowledge or in generalization in the contexts of literature.

### Critical Summary

Case studies have been used to address a variety of subjects and issues and have contributed to the theoretical and methodological state of the art of tourism research and scholarship. As noted earlier in this review discussion, this approach has been stereotypically perceived as atheoretical in tourism research. Such a perception or assumption has to do with what is meant by theory in tourism studies. From the standpoint of classical economics, the term *theory* usually connotes a set of principles, based on empirical evidence, that provide reliable, consistent, and verifiable predictions about the functioning of a system or phenomenon. In such a context, theory is not simply a model or a set of hypotheses, it is the formal articulation of cause-and-effect relationships that have been verified repeatedly, and that reveal insights into how the system or phenomenon actually functions. From such a strictly positivist perspective, one might argue that the term theory is often used inconsistently in young multidisciplinary fields such as tourism, and recreation and leisure studies, and that despite frequent debates on theoretical advancements, there is not much theory in these fields.

In contrast, in the evaluation of theoretical advances of tourism research from an interpretive perspective, theory can also be seen as a conceptual framework for understanding, explaining, and describing social phenomena, in which a theoretical advance is taken to mean the synthetic outcome of a dialectical exchange of ideas. As Edward Bruner noted, “social theory both reflects and is constitutive of changes in the world. It does not regard earlier work as totally discontinuous with the present or as fatally compromised politically, or as subversive of truth. It charts where we were and where we are going” (p. 462). It would therefore be simplistic and misleading to judge a prior study according to whether its theoretical status is still as valid today as when it was initially articulated, as in the case of Dean MacCannell’s *The Tourist* or John Urry’s *The Tourist Gaze*, both of which are ethnographic case studies of Paris in the 1960s and 1970s and of the United Kingdom in the 1980s, respectively.

In light of the methodological process for the generation of theories, future assessments of tourism case studies in theory building should depend as much on their concepts, frameworks, and propositions emerging from a research process, as on their empirical or implementational issues such as the strength of the method or the evidence grounding the theory. On these observations, case study research in tourism is as rigorous and systematic as other methods.

## CASE STUDY SURVEYS

---

Case study survey research is a research design in which a survey is administered to a case, either a small sample or an entire population of individuals, to describe an aspect or characteristic of that population. Researchers ask individuals in the population questions to examine individual self-reports of opinions, behaviors, abilities, beliefs, or knowledge. The responses are analyzed to describe population trends or to test questions or hypothesis.

### Conceptual Overview and Discussion

The purpose of case study survey research is to identify characteristics of a population by asking a number of questions of individuals in that population related to an issue. The population as a whole is generally not studied, although survey research does allow for collection of data from a larger number of people than is generally possible. Usually, a carefully selected sample is surveyed. The survey

is used to examine individual characteristics to find and describe trends in the population with a focus on learning about the population.

Case study survey research does not involve an experimental manipulation of conditions. It cannot be used to explain cause and effect and cannot be used to determine causal relationships with any degree of certainty. It yields a normative description of how the sample has distributed itself on a question and the response alternatives for every questionnaire item. It can be used to explore a variety of relationships, and can also be used to explore relationships between two or more variables. However, validity of the information gathered is contingent on individuals' honesty and willingness to participate.

### Application

There are several types of designs that can be used in case study survey research. The first is a simple descriptive design. This is a one-time-only survey that is used to describe the characteristics of a sample case at one point in time. The second type is a cross-sectional survey design where the researcher collects information from a population or several populations at one point in time. The third survey research design is longitudinal. Longitudinal designs follow the same or very similar populations over a period of time or at different points in time. They include trend studies that examine different samples from a population surveyed at different points in time, cohort studies where a specific population is followed over a period of time, and panel studies that survey the same individuals at each subsequent data collection point. Unfortunately, panel studies may suffer from a loss of subjects over time, leaving a smaller sample with possible bias.

Case study survey research design makes use of several tools to obtain standardized information from all individuals in the sample. Questionnaires or interview guides are the most common instruments used to collect data. The questions asked in the questionnaires and interviews may be either closed form where only certain responses are allowed, or open form where the subjects respond as they wish. The form used is determined by the objective of the question and the nature of the response desired.

A questionnaire is a form with questions that the individual completes and returns to the researcher. The individual chooses or completes answers to questions and provides basic personal or demographic information. The questionnaire may be mailed or online. Questionnaires that are mailed tend to have lower response rates than other survey tools, and there is no opportunity for the researcher to probe or question answers. However, they offer the greatest anonymity to individuals who are responding. Online questionnaires are considerably less expensive than mailed surveys, and offer the advantage of being convenient to complete and return.

An interview survey makes use of a form on which the researcher records answers supplied by the participant. The researcher asks questions from an interview guide and records responses. Interviews involve direct interaction between the individual and the researcher and provide a rich source of information. Unfortunately, they may allow subjectivity and possible bias from many sources. The interview guide can be structured with a series of set questions, semistructured with set questions and probes that are more open ended, and unstructured where the researcher has a general plan to follow, but no set questions. Interviews may be conducted as one-on-one in personal interviews, focus group interviews, telephone interviews, or electronic interviews.

Phone interviews may result in higher response rate than mail surveys. They can be more costly and time consuming than mail, but may be less expensive than face to face interviews. In telephone interviews, researchers have the opportunity to probe for additional information, but there is no opportunity for the researcher to observe body language or surroundings. The personal interview is the most costly approach, but offers an opportunity for the researcher to build trust with the individual and a setting in which the researcher can probe for further information and understanding. Computer technologies offer an alternative for interviewing that is less expensive and may be more convenient for both the researcher and the individual responding. The researcher can probe answers to questions but has no opportunity to observe the individual.

No response and item nonresponse are serious concerns in case study survey research. When

individuals participating in the research fail to complete all of the items in the survey, item nonresponse occurs. Individuals may not know the answer, may be pressed for time, may skip over questions, or may fail to record an answer. The number of non-responses varies according to the natures of the questions asked and the mode of data collection. These item nonresponses result on gaps in the results.

Nonresponse is an important issue in survey research that occurs when individuals in the sample population do not respond to the survey. There are many reasons for not responding, including lack of interest, forgetfulness, and unwillingness to participate. Unfortunately, this can result in data bias and is a serious difficulty. Evaluation of the results should include consideration of the non-response rates.

Case study research data can be found in many areas. The Gallup Poll may be the best-known survey used to sample public opinion in a population. The general public may also be familiar with market surveys researchers use to evaluate product satisfaction or political polls that provide data on public support of political figures or policies. A review of the literature reveals a plethora of case study survey research. For example: Survey research has been used in medicine to examine patient, nurse, and doctor perceptions and experiences. It has also been used to sample drug, alcohol, and nicotine use; sexual activity; exercise participation; eating patterns; sport activity; and a variety of other health behaviors. In education, surveys have been used in program evaluation, and to examine teacher, student, and parent perspectives. Survey research has been used to measure community needs as they relate to programs, courses, facilities, projects, or community involvement. Electronic surveys such as computer-assisted telephone interviewing (CATI), voice recognition (VR), and touch-tone data entry (TDE) questionnaires have been used to examine public attitudes and awareness around different issues and even consumer preferences and behaviors.

### Critical Summary

Case study survey research is a research design in which the researcher samples a population and uses questionnaires or interviews to ask questions related to a topic or issue to develop conclusions

regarding trends in the population. This type of research design is very useful, as it provides the researcher with the ability to sample a large number of people within a case quickly and economically. It also allows the researcher to sample individuals not located in close proximity to the researcher. Information can be gathered at one point in time, or over a period of time. However, survey data are self-reported information, reflecting only what individuals think, or think they should report, at that particular point in time.

## CASE STUDY WITH THE ELDERLY

---

Case studies of the elderly examine, describe, and at least implicitly advise on the governance of the quality of life and the health of the elderly, who often are chronically ill. These case studies are mostly undertaken by researchers in nursing studies and gerontology. The elderly are typically older than 75 years, but multiple body system affliction and psychosocial isolation are key differentiators. Several levels of care are usually required. Incontinency, diabetes, memory loss, depression, difficulties in motility, and the results of heart attack and/or stroke are often involved. Medical (hospital/nursing home) and/or community-based (home care) regimes of care are concerned.

The case studies typically involve the elderly, their bodies, social contexts, sensemaking, families, professionals, and the insurers. To be “elderly” has a complex and contested intersubjective meaning. The lived-body exists in a world full of textures, resonances, tones, relationships, and circumstances. Case study research chooses among a vast array of bodily informed possibilities of observation, reflection, and analysis to provide insight into the elderly as person, small group, subcategory, and/or element of organization. The term *elderly* is politically and theoretically laden.

### Conceptual Overview and Application

Ageism or the wholesale discrimination against the elderly dominates in advanced industrialized countries. Being elderly is mostly stigmatized—it is characterized as being “past it,” “giving up,” and “being a burden.” For some, old age is identified with unattractiveness, dependence, loss, and decline. For others, the elderly are viewed as a “problem” because they are “not productive” and form a “welfare burden” that gets ever larger. In response to such negative stereotypes, some elderly persons may claim to be “active,” “purposeful,” and to make a positive social contribution. They may internalize and then deny negative stereotyping. Many elderly buy into the paradoxical antiaging “dream” by acting fit, dressing fashionably, and traveling extensively. *Acting* is used here in Erving Goffman’s sense of performing a social position that is normatively or ethically laden. The “young-old” (i.e., the elderly with a youthful “lifestyle”) or “not-old” (i.e., the elderly who actively oppose being seen as “old”) try to deny aging. Their (life-)stories lead to case studies about “positive aging” and “proactive lifestyles.”

Some elderly embrace interdependence and reciprocity and fight for a more inclusive society. Case studies about them stress caring about others. Directly experienced community is their key norm. Their self is constructed around immediate relationships and personal commitments. In a post-modern culture of rootlessness, hyperreality, and impermanence, the emphasis on socially committed togetherness and the celebration of community and closely knit relationships is exceptional. For this group, neighborhood is a key value.

Case studies of the elderly are framed in an opposition between naturalism and normativism.

Naturalism accepts physical deterioration with age as inevitable and understands chronic illness to be independent of individual or social values. Disease is a natural phenomenon entailing diminished functional ability. The aged who are in principle chronically ill are simply “diminished” or “lessened” in their abilities. Their condition just is a biological fact. “Agedness” rests thus supposedly on a value-neutral core, though there are economic or political choices or values involved in the choices of care responses. From this point of view, on the one hand, there are the value-neutral facts of medicine understood as a science. And on the other hand, there is the value-laden world of political or economic choice. Proponents of naturalism argue that the two can and must be radically divided.

Normativism does not accept the naturalist take on aging. Normativism argues that every norm (e.g., “healthy”) is value laden and has to be examined in its ethico-social context. “Diminished in abilities” makes sense only in accordance to a norm—which abilities are diminished, when and why? Are “abilities” defined in terms of physical labor, wisdom, or something else, and why? Normativism focuses on the ability to perform intentional actions and achieve goals, while naturalism focuses on biological factors often understood in statistical terms.

Case studies of the elderly tend to embrace normativism. If health, as in naturalism, amounts to preserving the organic functional ability to make species-typical contributions to survival and reproduction, then health can be objectively and statistically determined—that is, subjects’ perceptions or awareness are not relevant. But if a normative evaluation of the person’s body and mind is a necessary element in the care of the elderly, then case studies are necessary. “Being elderly” can have to do with pain, suffering, and disability—that is, to the experienced inability to act and to do or achieve things as one wishes and/or one expects to be able to do. It then includes: sensory impairment; problematic mobility and falls; age-related changes in memory; depression, stress, and coping; dementia; long-term healthcare and its rationing. But “being elderly” can also focus on those who are not in pain, suffering, or disabled. Case studies of the elderly can study well-being, fitness, and the positive manifestations of emotional and sexual expression in later life. Expectation and intentionality are

crucial. Aging and illness experiences are understood here to be normative and are studied as such.

Case studies of the elderly can clarify who makes which (health)care decisions and how. Obviously the client must play a role, but also the client's loved ones, as well as the healthcare specialists and various representatives of the socioeconomic powers. Care is organized along a dual power structure, with medical care mainly following the naturalist biostatistical line. Doctors tend to treat disease and follow evidence-based medicine. They may minimize issues about what the patient actually feels or experiences. Illness and disease, health and care, can all be considered socially constructed, comprising social-economic and cultural values. Although advocates of naturalism believe that choosing "survival" as the key norm for healthcare is value neutral, opponents disagree. For opponents, choosing survival displays links to social Darwinism, a viewpoint mirroring (neoliberal or hypercapitalist) economic competition and political assumptions. The critical structuralists point out that the "primacy of the self" that is assumed as of paramount value by the humanist concept of survival is a sociohistorical construct that can be criticized as so many justifications of the social regime of private property.

Normativism precommits case studies to humanist values by taking the bodily, social, and contextual experiences of the elderly into account. The integrity and dignity of the elderly are normativism's key dual values, embodying respect for autonomy. The negative term *ageism* describes disrespect and discrimination against the elderly. In terms of care, the positive value is *person centered*. Dignity and integrity, in the care of the elderly, entail doing justice to their quality of being human. Concretely this includes (a) an adequate means of existence, (b) freedom from intense continual pain, (c) a minimum of liberty, and (d) the practice of deference that honors basic self-respect. For the elderly, these are not self-evident matters.

Some elderly are totally dependent, in pain, not permitted social choices, and exposed to care that negates their self-worth. Often, the efficiency of washing or grooming, dressing, and feeding is maximized and the dignity of the cared-for is ignored. For those whose lives have embodied moral maturity and high standards of action, losing

all contact with their moral identity is enormously damaging. Often the cared-for are treated as if they have no moral will or relevant ability to judge circumstances. The dignity of personal identity is endangered. Nakedness, inconstancy, and memory loss, for instance, form for many a continual danger of shame and embarrassment. Respect for the dignity of the elderly may sound very abstract, but appropriate case studies have demonstrated that it is really quite concrete.

Ingrid Randers and Anne-Catherine Mattiasson describe, for instance, the treatment of an elderly woman in a wheelchair. The woman feels humiliated when a young caregiver tells her that she must go to bed at 8 p.m.; she is in a wheelchair but is perfectly capable of making her own choices. A caregiver sees her near midnight, sitting alone staring out a window, having retreated into her own melancholy. The caregiver questions her, reassures her that she is understood, that no one is angry, and brings her to bed, promising to check on her regularly during the night.

Integrity and dignity entail respect for the (a) corporal, (b) psychological, (c) informational, and (d) cultural self. Integrity means being respected, being treated with dignity, and not being physically or psychologically harmed. Dependency increases the chances that integrity is violated. Case studies are used to examine whether the privacy of belongings, space, and body have been violated. Examination of the elderly's lifeworld include descriptions of bodily presence (embodiment), examination of temporalization (how one lives in past, present, and future), attention to mood (emotional attunement), research into spatiality (sense of place), and sensitivity to the quality of interpersonal relations (intersubjectivity); other themes include: the sense of selfhood, having goals (convictions, sense of purpose), and uses of discourse (communication).

These lifeworld criteria are used to examine the elderly phenomenologically. While the categories are rich and broad in scope, the methods of applying them are controversial. If handled poorly, lifeworld analysis becomes mere researcher projection. In the data collection, the other must be heard, responded to, and valued. Relationship building requires self-awareness, reflexivity, and attention to values. Especially because the elderly, for whatever reasons, may find it difficult to speak out for

themselves or to assert their own perspective(s), case studies are often the most person-centered research possible.

Normativists stress the need to feel connected and close to others. In the 1960s the elderly were prized, for instance, by Bertrand Russell in *New Hopes for a Changing World* and Erik Erikson in *Childhood and Society*, for displaying stoic wisdom and distance from the hypes of daily concerns. Today an active concern with life in the face of death is often seen to be characteristic of integrity, while postmodern frantic consumerism and depression, as described by Jean Baudrillard, are thought to be all too common. Integrity is thought to have to do with life as something necessary, whole, and meaningful. The person-centered focus emphasizes *Gemeinschaft*, the shared quality of life, and communitarian well-being. The valuing of interdependence, recognition, respect, and trust are highlighted.

### Critical Summary

Case study research of the elderly is profoundly normative. Responsibility for “care for the self” during the last few years of life is at issue. The processes of letting die and/or making live are at stake. Governments in Europe and the United States started in the 1970s to abandon the elderly, claiming that responsibility for the elderly was too expensive for the collectivity. Thus the elderly have been redefined as individuals, responsible for their own autonomy and (self-)care. Morbidity, mortality, vitality, and longevity have been privatized and individualized. Institutional (hospital or nursing home) care has been replaced as much as possible by care at home. Doctors and other highly trained professionals have largely been replaced by less-trained nurses or by volunteers.

The care regime considered desirable, legitimate, and/or efficacious varies enormously depending upon one’s “politics of life itself.” Case studies of the elderly originate with the interventionists who in the name of life and health, humanism, and social justice, believe that an active biopolitics is justified and desirable, and who are committed to defending the quality of life of the elderly.

## CASE-TO-CASE SYNTHESIS

---

Case-to-case synthesis is one of several secondary analysis techniques that can improve the influence and usefulness of both qualitative and quantitative case study research results. Such syntheses also

hold promise for addressing policy issues at the national level as they build understanding across several instances within a problem space, thus generating knowledge with broader applicability.

Other secondary analysis techniques appropriate for case studies are research reviews, secondary re-analyses, and metasyntheses. Research reviews are critical summaries and interpretations of the available research literature on a specific topic. As such, they are similar to literature reviews that focus on the theoretical framing of the study, the design, methods, analysis techniques, and/or findings of several studies. Secondary re-analyses are conducted when researchers have access to original data produced with a similar research focus, agenda, and data collection methods across unique settings, informants, or contexts. Secondary analyses, or re-analyses, of data using an improved lens or interpretive framework can generate new insights and contribute to knowledge in the problem space. Metasyntheses focus on theory building using the assumptions and techniques of grounded theory methodology through which the data, methods, findings, and theoretical frameworks of independent studies are examined with the goal of generating a synthesis of results across the collection of studies.

The focus of this entry, case-to-case synthesis, involves the in-depth examination of a collection of case studies—albeit ones with a common focus, method, or outcomes. The cases could be instances in a multi-site case study or could be case studies conducted independently. Multi-site case studies are typically designed to be intentionally integrated, whereas independently conducted studies are not. In the latter instance, the synthesis is intended to build integrative understanding of the problem space studied in the independent case studies. Researchers can explore several instances of a common or similar phenomenon, event, or population and can consider the combined cases as the collective case.

Because synthesis is fundamentally interpretive, different researchers may well focus on different aspects of the cases, reflect on and integrate those accounts into their own experiences, and render different syntheses. This is similar to what we would expect from two different integrative research reviews of the same corpus of studies. Because researchers bring different conceptual lenses to the task, two reviews of the same body of

research would likely be organized differently, emphasize different elements of the studies, and draw different conclusions. In fact, this value-added interpretation is what makes intriguing research reviews—and syntheses of case studies—interesting and scholarly. It raises the resultant work above the mere recitation of previous studies—impoverished, annotated bibliographies—so soundly critiqued.

### Conceptual Overview and Discussion

Case studies vary in design and can involve gathering qualitative and quantitative information from a single intact group or one- and two-group pretest–posttest designs. The strength of case studies lies in their in-depth explorations of bounded systems over time that respect situated factors and position the target constructs in authentic contexts. This very strength, however, can limit application of the results. End users may judge the bounded system as too idiosyncratic for their problems, situations, and constituents. Nevertheless, synthesizing across cases holds promise for building knowledge that is more generally useful and can inform policy, programs, and practice.

For example, case studies have a rich history in law and medicine and growing application in healthcare, the social sciences, and education. Reviews of individual court cases and judicial decisions have served as the basis for procedures and standards regarding legal issues—case law—while individual case results in medicine have been integrated to standardize treatments and to generate hypotheses about specific diseases and illnesses. Similar trends can be found in healthcare and social welfare but are not as apparent in education. This concern and the lack of education research's impact on policymakers and decision makers has become an important issue in the education research community.

In multi-site case studies, researchers deliberately design a study to describe and analyze the phenomenon of interest in several instances. This intentionality drives the research design by utilizing common questions, procedures, data sources, propositions, and analyses across several bounded systems. The analysis, in turn, leads to assertions that apply to each individual case and to the collective case that more fully represent the entire problem

space. The use of such anchors as similar problems, questions, data collection, and interpretive frames produces results that facilitate generalizability to other, slightly different, bounded systems.

A similar approach can be applied to a research agenda that involves serial studies of a problem space over time. Each case study may be conducted independently and sequentially, but they all address a common problem with similar research questions, designs, data collection, and data interpretation—even though implemented in different settings with somewhat different content or participants, or both. In this approach, data from several case studies can be re-analyzed as a collective dataset or the results can be synthesized across the mosaic of the case studies.

The literature describes two central analytic strategies for case-to-case comparisons leading to synthesis—case-oriented and variable-oriented approaches—as well as a mixed approach. In the case-oriented approach, one case is analyzed and a grounded theory or working explanation is developed. This working explanation is then applied to subsequent cases to test the robustness of the explanation. In the variable-oriented approach, particular themes are identified and compared across cases. The complexity of specific cases is downplayed to highlight the thematic analysis. While this may be a disadvantage, it can be overcome by relying on mixed approaches where some balance is struck between the full comparative analysis of cases and the discrete, more focused analysis of variables or themes.

It is important to note that findings from studies, even those involving randomly selected samples, are not strictly generalizable to other populations. While this logical error is frequently made in research reports, the logic and assumptions of random sampling and statistical inference do not permit the seamless application, or generalization, of results from the original study to a new, presumably different population. However, the use of analogy and compare–contrast reasoning allows potential users of research results to determine for themselves if a study’s results will be useful to their specific problem, situation, and constituents. This is a more inclusive, stipulative definition of generalizing—one that encourages and values syntheses across studies but relies on a different logic than that of probabilities.

Synthesis—the process of integrating parts to form a whole—suggests that the outcome is more complex than a mere aggregation of component parts. The process is more closely related to inferring and drawing conclusions than to probabilistic generalizing. However, where generalizing statements integrate salient elements, conditions, and explanations, applications to other instances are presumed. Such applicability is one criterion for judging the value of the synthesis. The logical processes of syntheses are inductive, analogical, and interpretive.

### Application

A few examples of multiple case studies and case-to-case synthesis can be found in the intersection of literacy and science education research focusing on science literacy for all. The brief summaries of these examples illustrate the procedures outlined above and their application to short-term studies and a long-term research program.

#### *Teacher’s Beliefs*

An example of a case-to-case synthesis comes from the work of Deborah Dillon, David O’Brien, Elizabeth Moje, and Roger Stewart, who found that previous research on language, literacy, and science education had considered several elements: classroom questioning techniques, verbal interactions, quality of texts, readers, and reading-to-learn science. They further established, however, that research had not addressed aspects of the problem space dealing with the interaction of teachers’ beliefs about teaching, their understanding of science content, and their uses of literacy events in secondary science classrooms; also, previous research had not sufficiently addressed how teachers selected, structured, and implemented literacy events. Based on their assessment of the problem space and its development, these researchers decided to use the methodologies of symbolic interactionism and ethnography to explore three cases of secondary science teachers’ beliefs, instructional decisions, and implementation of literacy events. Their design was intended to produce findings that could be applicable across more than a single setting; they designed a stepwise, case-to-case analysis.

They conducted yearlong case studies of three teachers teaching students in their science classrooms. Common data sources (field notes, videotaped and audiotaped lessons, interviews, student work samples, study guides, laboratory sheets, lesson plans) focused on each teacher's teaching philosophy and knowledge of science content, how these influenced the selection of literacy events, and how these events were organized and delivered. The data were analyzed stepwise as the inquiry progressed using constant comparison; emerging patterns and categories were supported, negated, elaborated, or refined as additional information was collected and interpreted.

Results for each case study were developed, and common trends across the three cases were synthesized and reported. The researchers looked for similar and different patterns across the data analyses and specifically focused on teaching philosophies and literacy practices. Their synthesis suggested that these teachers attempted to support student learning based on distinctly different philosophies about science teaching, instructional organization, and definition of science literacy.

### *Coauthorship*

As another useful example, Marilyn Florence and Larry Yore conducted a multiple case study that examined the coauthorship process in two research laboratories. The study focused on two cases comprising five writing teams, one in Biochemistry and Microbiology and four in Climate Sciences. The role of the research supervisor, the role of the student (graduate and postgraduate), the interactions of the supervisor and the student, the activities and processes inherent in the coauthorship process, and the students' expertise, scientific writing, and entry into an academic discourse community were documented.

Multiple sources of data and multiple methods were used to document the coauthoring of research reports, the alignment between the students' and their supervisors' beliefs about writing, and whether coauthorship helped students become expert science writers. Data from cases were interpreted progressively starting with the Biochemistry–Microbiology case because other researchers had studied similar cases in this science area. Assertions derived from this case established expectations but

did not limit them in later analyses of the Climate Sciences cases.

The syntheses across the cases led the researchers to conclude that several activities and processes were found to be common across the teams: planning, drafting, and revising. Habits of mind, beliefs about the nature of science, and abilities to communicate the “big ideas” of science were evident. Elements of scientific and writing expertise, facets of enculturation into scientific research and discourse communities, academic civility, and the dynamics of collaborative groups also were apparent. There was healthy tension and mutual respect in the research groups as they attempted to make sense of science, report their results clearly and persuasively, and share the responsibilities of expertise. The novice scientists came to appreciate that the writing–editing–revising process influenced the quality of the science as well as the writing.

### *Science Writing Heuristic*

As a third example, two research teams—Mark McDermott and Brian Hand as one team, and Murat Gunel, Brian Hand, and Vaughan Prain as the other—set out to synthesize the results of six case studies of the Science Writing Heuristic (SWH). The SWH is a pedagogical approach that uses writing to promote student learning in science. The Hand–Prain research group has been involved in the language–science learning research agenda for nearly 20 years; their research for the past decade has focused on SWH and its application in different instructional settings and in different science content areas. Their cross-case synthesis strategy was a secondary re-analysis of the original qualitative and quantitative data.

The re-analysis of the quantitative data by the second team used original test items and responses from different pretests and posttests across the 6 two-group case studies and followed a 3-step process. First, test items were reviewed and consistently classified as extended recall (retrieval of knowledge), analogy (cognitive, source, and target domains), and design (defining problem, transfer of knowledge, problem solution) questions; percentage correct scores were calculated for these question types and the total pretests and posttests for treatment and comparison groups. Second,

independent one-way analysis of variance (ANOVA) was conducted for each study on the treatment and comparison groups' total pretest-posttest differences. Third, independent two-way ( $2 \times 3$ ) analysis of covariance (ANCOVA) was conducted on treatment and comparison groups' posttest performance on the question types using pretest performance as the covariant.

These re-analyses revealed trivial to large (0 to 1.0) positive effect sizes for all studies. They concluded from the collective case that:

- Using writing-to-learn strategies was advantageous for students compared to those students using the more traditional science writing approaches
- Using diversified types of writing enabled students in treatment group to score significantly better on conceptual questions and total test than those in the comparison situations
- Importantly, when the cognitive demand of the question is increased from an extended recall to a design question, there are significant performance differences between comparison and treatment groups in favor of treatment

The authors argue that the use of writing-to-learn strategies requires students to rerepresent their knowledge in different forms, which fosters enhanced learning opportunities, and that traditional writing strategies tend to favor replication of knowledge.

Complementing this quantitative re-analysis, Mark McDermott and Brian Hand conducted a qualitative re-analysis of these case studies with the purpose of documenting the cognitive advantages and affective responses of writing-to-learn science approaches; they utilized a consistent interpretative framework and updated theoretical foundation across the collection of six studies. Identical and similar questions in the protocols were clustered under common intentions; student responses were open coded for each study individually to reveal potential themes within these intentions. Students' spontaneous comments related to learning and affective dispositions were also noted.

A master spreadsheet of key ideas from each study was developed for the collective case, and axial coding was applied to identify subthemes, percentages of respondents, and illustrative responses

within the themes. Finally, selective coding was applied to create tentative assertions pertaining to each theme. The research group discussed these tentative assertions to develop overall assertions for the collective case. Specific responses clarifying a student's rationale for agreement or disagreement with each theme were selected and used to justify the cross-case assertions. They asserted that students believed:

- Writing-to-learn activities helped them learn. Students noted several characteristics that indicated increased cognitive involvement and promoted enhanced clarity.
- Writing to an audience other than the teacher was beneficial. This caused them to translate their ideas into different terminology and to create text appropriate for the audience.
- The process of drafting helped them construct knowledge. They could identify changes in their own understanding corresponding to changes in text.
- The writing tasks were unique and focused on science understanding, not creative writing.
- Several specific characteristics could be identified to promote learning benefits, but mechanical writing did not guarantee improved understanding.

The researchers concluded that these re-analyses provided consistent results about cognitive advantages and affective responses across the six quantitative and qualitative case studies and a more compelling, comprehensive description for the effectiveness of writing-to-learn science.

### Critical Summary

Quality research is not simply the application of a one-size-fits-all approach, as might be assumed by the gold standard in the United States. Nor is quality research a simplistic question of qualitative or quantitative approaches. Rather, quality research involves alignment of the problem space, development of the related knowledge base, available technologies, and the design. Furthermore, quality research involves consideration of progress in the research agenda and the desire to extend knowledge about important problem spaces, which produces trustworthy results and compelling arguments

reflecting prior inquiries and applicability to similar problem spaces and settings.

The explication of case-to-case synthesis strategies and the examples above describe processes for building generalizing knowledge across case studies. In the current research climate where randomized controlled trials are considered the gold standard for research in education, such explications and examples offer valuable alternatives for generating knowledge that can inform policy, the education of teaching professionals, and programmatic initiatives. Case-to-case synthesis—whether conducted within an intentionally designed, multi-site case study or through the identification of a collective of independently conducted case studies—provides researchers with rigorous, insightful, generalizing knowledge about a problem space.

---

## CASE WITHIN A CASE

---

Case within a case is a specific research strategy that can be used when employing the case study methodology. This research design involves dividing a larger phenomenon of interest (the case) into a subset of smaller meaningful units (subcases). These subcases can then be used to compare both similarities and differences within and across the subcases in order to glean insight into the larger phenomenon of interest.

#### Conceptual Overview and Discussion

The case study is a method for doing research that involves gaining an in-depth, longitudinal understanding of a single phenomenon of interest within its natural context as it occurs over time. This research strategy is excellent for providing realism but is often criticized for its lack of control. Indeed, control is rarely something that those who use the case method strive to attain because they usually follow a constructivist philosophy and tend to view activities as being interrelated and interacting but not necessarily causally deterministic.

Thus in case research the purpose is to describe a sequence of interrelated, contextually bound activities rather than a few well-isolated causal variables. However, while asserting causality for a few independent variables is not the goal, researchers do

still seek the ability to abstract away from the details of the specific phenomenon to provide generalizable theoretical statements. This is where identifying multiple subcases within an overarching case becomes a useful tool.

Dividing a single case into a subset of smaller cases provides the opportunity to identify both similarities and differences across the subcases. What is gained from this form of analysis often serves as the foundation for the theoretical generalizations that are difficult to ascertain when examining only a single case. For example, when researchers are looking for similarities across cases they will often use the subcases as independent “natural experiments” in order to confirm or disconfirm emerging conceptual insights. In addition to identifying similarities across cases, researchers can also examine differences. Differences between cases are used to help the researcher identify “what did not happen” and can help to dispel “naturalizing myths.” Thus, rather than attempting to determine causal relationships across a few isolated variables, as is done in traditional variance-based approaches, differences between cases provide new ways of seeing and understanding how a given phenomenon may unfold in each of the subcases. Accordingly, dividing a single case into several meaningful subunits provides the structure that helps in making the elusive conceptual leap that is necessary to create theoretical generalizations.

In starting a case-within-a-case study, it is first necessary to identify a bounded system. That is, as in a regular case study, researchers should start by identifying a phenomenon of interest and the boundaries that will delimit what will, and will not, be studied. When the boundaries have been defined, the next step is to identify the subcases for comparison. It is usual that between 4 and 10 subcases will be selected, a number small enough to allow in-depth study and understanding, but large enough to allow for meaningful comparison. The subcases, as the case itself, should be purposively selected on the basis of satisfying some pertinent theoretical criteria.

If studying strategy implementation, for example, it may be useful to examine how the strategy is implemented by different organizational subunits, such as teams, functional departments, geographical sites, or operating companies. Thus, the subcases

would be formed through examining how the strategy (the case) is interpreted and enacted in each different bounded system (the cases within the case). While a strong theoretical rationale for case and subcase selection is important, another key logistical consideration when choosing cases is accessibility. The theoretical utility of the case is irrelevant if access cannot be gained to the research site. Thus, cultivating a relationship with an internal sponsor is a key component of case study research.

Once the case and subcases have been selected, the next step is to begin collecting data. This step again is similar to a single case study in that data can be collected from multiple sources using multiple methods. Different forms of data that are often used include interviews, observations, historical archives, surveys, official documents, and popular press articles. However, it is important to note that when collecting data, the case is the primary referent for choosing which methods and sources to use. In other words, the methods and sources should be chosen based on their ability to provide insights into the phenomenon of interest.

Therefore it is useful to create a case plan ahead of time in which initial decisions regarding types and sources of data have been made. However, it is also important to remain flexible to allow the pursuit of new data sources and questions as contextual understanding increases. A key difference between a single case study and a case-within-a-case study is that it is not uncommon to have multiple researchers collecting data in studies with multiple cases where the work is divided on a per case basis. Having a case plan in this instance is even more important because it helps ensure that similar sources and methods have been used to collect the data across the subcases, which can in turn help demonstrate the robustness of cross-case comparisons.

The case analyses and write-up typically start with an in-case analysis of each of the subcases to ensure that a good understanding of each subcase has been acquired. At this point, interesting empirical and theoretical themes will start to emerge. After the *in*-case analysis is done, the next step is to look *across* cases for similarities and differences among cases. While these steps do appear linear, overall the case analysis should be pursued in an iterative fashion where there is a constant comparison between the overall case and the individual

subcases. As findings begin to emerge from cases, it is important to remember that while researchers want to stay close to the data, the final report should involve taking a creative conceptual leap to make theoretical generalizations that could be of interest to a broader population.

### Application

An exemplar of the case-within-case approach can be seen in Ewan Ferlie, Louise Fitzgerald, Martin Wood, and Chris Hawkins's study of the non-spread of innovation. The case was organized with the purpose of understanding more about the diffusion of evidence-based innovations in healthcare organizations. The overall case, the National Health Service (NHS), was divided into eight subcases. Each subcase consisted of a single innovation that subsequently was followed throughout the diffusion process.

The subcases were purposively selected based on two criteria identified as relevant to understanding the overarching case. First, the team wished to examine the potential influences of differing healthcare contexts on innovation, so subcases were drawn equally from acute and primary care settings. The second criterion was based on whether the innovations were supported by strong or contestable scientific evidence, because the researchers theorized that this would be a central factor that influenced the spread of the innovation. When the researchers had selected the cases, they established a plan for data collection, a process that took place over a 3-year period. Data were collected from a variety of sources, including semistructured interviews, minutes of meetings, policy guidelines, and published and nonpublished reports.

Data analyses followed an iterative process in which, first, single subcase studies with common formats were produced. These then formed the bases for a thematic analysis that was conducted across the subcases. Given the large amounts of very rich data that are produced in such studies, it is quite usual for researchers to publish different parts of the case/subcases in different journal articles, and even to provide book-length accounts. Irrespective of how these accounts are disseminated, a vital step is to proffer theoretical generalizations.

The Ferlie team suggested that while strength of the accumulated scientific evidence influences which innovations spread, the spread of evidence is mediated by the social and cognitive boundaries between the professional groups that are responsible for enacting the different innovations. These "boundaries" between professional groups (e.g., doctors, nurses, hospital consultants, advocacy groups) have the potential for retarding the spread of the innovation. It is then argued that though this study took place in the medical field, these findings can be applied to other large, complex multiprofessional organizations such as consulting firms, pharmaceuticals firms, and major software houses. It is precisely this type of theoretical generalization emanating from subcase comparison that makes this method so compelling.

### Critical Summary

While dividing a single case into multiple subcases is useful for generating theoretical insights, it is important to remember that a primary benefit of case studies is that they allow in-depth study of complex phenomena. Thus, researchers should be cognizant of the trade-offs inherent in creating subcases. As the number of subcases increases, the amount of information that can be gathered and used for each case decreases. Hence there is a constant need for researchers to balance the tensions between examining the overarching case and the subcases.

## CAUSAL CASE STUDY: EXPLANATORY THEORIES

---

The essence of explanatory theories is to answer “why” questions. To do so, causal linkages between events must be identified; this is what causal case studies do. They tell a story of a sequence of events or processes and thus lend themselves to building explanatory theories that generalize from the story.

### Conceptual Overview and Discussion

Scientific explanations involve making causal statements, such as “a lightning strike ignited the fire,” or “bacteria caused the infection.” In social sciences, explanations involve volitional actors—human beings—and therefore simple mechanical causality as in the above examples does not apply. To explain, for example, why the crime rate in certain neighborhoods has increased, or why a particular business firm has managed to outperform its competition, a whole network of causally connected factors needs to be identified. By focusing on telling a story—a temporal sequence of events in their context—case studies can accomplish this better than most other research methods (which are based on analyzing variances and cannot uncover causal direction).

Exploratory and descriptive case studies tell a story (what happened and how), but they do not pinpoint causality (why it happened) beyond identifying the chronology of events. For example, an exploratory case study may reveal that a patient had a parent with heart disease, was sedentary and consumed a high-fat diet, then had a heart attack. A descriptive case study might tell a story about a business firm with declining sales and profits, unmotivated employees, and lagging investment in research and development. While exploratory and descriptive case studies are important, they do not provide explanations or causal connections. Causal case studies do that, through extended research design and data analysis.

Causal case studies start with description. No explanation can be reached before the phenomenon of interest, whether a particular heart attack or superior business performance, is described; that is, we have a descriptive understanding of how the

phenomenon manifests itself and what sequence of events has preceded it. But a temporal sequence of events is not a sufficient indication of cause–effect relationships; to uncover those, the case study researcher must take the analysis further. This entails looking for patterns, or themes, in the data. For example, maybe in neighborhoods with increasing crime rates, families with stable incomes have started moving elsewhere in search of more spacious accommodations, followed by local businesses. Or maybe businesses that outperform their competition have uniquely differentiated their products.

### Application

Describing the case story and identifying and analyzing patterns within or across cases and iteratively comparing them with the data will allow researchers to uncover the causal networks at play in the focal case(s). They will be able to explain that businesses with superior performance are in tune with the needs of different customer groups, have chosen to serve one or a few of them, and then acquired the necessary resources and aligned all their activities to serve their customers exceptionally well, at a price customers are willing to pay. Customers reward them with profits, and they attract more customers with similar needs. Competitors are unable to copy what these superior performers are doing. This kind of causal explanation of a particular case is not yet an explanatory theory.

To move from causal case studies to an explanatory theory, one final step is required: Researchers must generalize from their particular causal explanations of single or multiple cases. This is an integrative and interpretive step, as researchers must bring the total of their analysis to bear in order to distill the essential causal connections at play. For example, such generalization may yield the resource-based theory of the firm, or the value activity model developed by Michael Porter—both of them explain superior performance of business firms.

Explanatory theories can arise from a single case study, such as Graham Allison’s study of the Cuban missile crisis, which yielded three plausible theories of organizational decision making. While a single case can give rise to an explanatory theory, multiple cases—analogue to replicated experiments—give us more confidence in the emerging theory, validating it both internally and externally.

An example of causal case study based on multiple cases is Ann Langley and Jean Truax's investigation of new technology adoption in small manufacturing firms. They conducted longitudinal case studies of five smaller manufacturing firms with two data collection phases one year apart, using participant interviews and available documents. Detailed descriptive chronologies for each firm's technology adoption process were developed and summarized in visual flowcharts that captured the complex causal relationships between choices made and various facilitating and inhibiting contextual elements (e.g., financing becoming available, or a strike). Comparisons of the causal sequences in the flowcharts and other visual displays allowed the authors to identify cross-case patterns of a technology adoption process that led to an explanatory model, consisting of three sub-processes: strategic commitment, technology choice, and financial justification.

### Critical Summary

By telling a rich, contextual story—what happened and how—case studies naturally lend themselves to discovering connections between causes and effects, that is, to answering “why” questions, the basis of explanatory theories. Researchers conducting case studies can stop at describing “what and how” and explaining “why,” but in order to induce an explanatory theory from their work, they have to make the integrative and interpretive step to uncover the general causal mechanism beyond their particular cases.

## CHARACTER

---

Within the realm of narrative analysis, the notion of character can be understood in two ways. The first is the understanding of who the social actors are and their importance to the narrative. The second use of character is a way to describe the overall theme or tone of the narrative.

### Conceptual Overview and Discussion

There is more than one way to do narrative analysis. As Catherine Kohler Riessman points out, narrative analysis can have different foci. Thematic narrative analysis is an examination of the content of a narrative. The researcher is looking for reoccurring themes in the narrative that the participants construct and present. It is not so much a question of how the narrative is presented, but what it contains. Conversely, structural narrative analysis focuses on the arrangement and organization of the narrative. This form of analysis has its early roots in the work of narrative pioneers William Labov and Joshua Waletzky. They were among the first social scientists to articulate the form and structure of narratives.

When doing performative analysis, the researcher is examining the context of the narrative. Premised on Erving Goffman's dramaturgical theory, a performative analysis is aware that the narrative is not a verbatim recreation of events, but an identity presentation that incorporates sociocultural influences. It also recognizes the researcher/interviewer as a critical element of the narrative. The narrator is constructing and presenting him- or herself to a particular person, at a particular time and place. When the narrative is analyzed as a performance, one can see where C. Wright Mill's sociological imagination comes into play, as the connection

between private troubles and public issues is evident in a single narrative.

The last, and perhaps the most underdeveloped and least representative of the latest “turn” in social science research, is use of narrative analysis to explore visual material. Researchers in this subfield of narrative analysis take their guidance from thematic and performance analysis methods. This means understanding the visual as representative of the experiences and social world of the visual creator.

Within each of these subfields of narrative analysis one sees that the first notion of character (who are the social actors, and what is their importance to the narrative?) has a different level of focus. Doing thematic analysis means that with a focus on more societal or global issues, the actual characters are not of primary concern. The related acts and understandings tend to be at the center of analysis. Similarly, for structural analysis, it is not the actors in the narrative that are important, but the sociolinguistic elements such as clauses and word choices that become paramount to the analysis. It is with the last two forms of analysis, performance and visual, that the characters of the narrative become more important to the analysis process. In performance analysis the characters in the narrative are important to contextualize and situate the narrative in the larger sociocultural structures.

The other way that character can be understood in narrative analysis is to look at the overall tone and timbre of the narrative. This would involve identifying key elements and themes that would pervade different people’s narratives and set them apart from others. This can be connected to the concept of genre. As narrative analysis has its historic base in literature, narrative researchers draw on literary genres to explain the types of narratives people present and why a particular genre form was selected. This could include presenting narratives that are comical, dramatic, heroic, tragic, and so on, as a way to get a certain point across to the audience and/or to make an identity claim.

### Application

David Knight, Robert Woods, and Ines Jindra, in a case study project, looked at the differences in the way young men and women related their Christian

conversion narratives at a small private university in Michigan. They recognized that conversion narratives by and large have similar structural elements, themes, and identifications that set them apart. What had been missing, they argued, was an understanding of the degree to which gender shapes the communication of the conversion narratives. Drawing upon a more performative understanding of narrative in this case, the researchers questioned what the connection was between gender and the way a narrative is communicated.

One of the findings that is exceptionally pertinent to this entry is their discovery of the participants’ use of character. In particular, who do the participants use as the central character in their conversion narrative? They coded for two broad categories in this instance: (1) self-oriented, and (2) other-oriented. As the codes would suggest, with a self-oriented central character, the narrator is the one driving the action in the narration. With the other-oriented central character, the person or persons moving the action at a critical juncture of the narration are not the narrator. This could include friends or family.

After analyzing the narratives, Knight and his colleagues found that when males told their conversion narratives, they were the central character. To illustrate this, they provided the case of Eric. Raised in a Christian home, Eric included no one else, such as his parents and family, until the end of the narrative where the researcher probed for more details. Conversely, females tell of others being central characters to their conversion narrative. Marcie, whose narrative they presented, emphasized the role a young male friend of hers (and subsequently his Christian friends) had in her narration. Marcie presented herself almost as a bystander to the events that led up to her decision to convert to Christianity. In these findings we see that gender does play a role in how one communicates a (conversion) narrative, by looking at who occupies the central character role.

Taking into consideration the second understanding of character (the overall tone of a narration), Mike Bury sets out to articulate the different ways one can analyze illness narratives. He sets the scene for his argument by stating that chronic illness has a “heterogeneous” character in that its symptoms affect multiple aspects of everyday life. As such, there are two narratives that come to be

developed: biomedical and lay narratives. This heterogenic character of illness permeates the narratives one tells about an ongoing illness.

For Bury, this notion of the character of a narrative is most detailed when discussing contingent forms of illness narratives. In this broad form, the researcher is analyzing narrators' articulation of their knowledge and beliefs as it relates to the onset of their illness, the illness's progression, and its affect on themselves and others around them. The contingent character, as Bury describes it, can be roughly understood in two views. The categorical view presented in a narrative involves the separation of what is normal and abnormal. This is representative of a biomedical understanding of illness. The spectral view understands that there is no firm distinction between what Bury has distinguished as illness and disease; here it is more a question of degrees. As such, illness in narratives that take this viewpoint is emergent in character; the social and psychological play a predominant role.

### Critical Summary

Within the social science use of narratives, character tends to be a concept that is largely absent from the literature. Nonetheless, depending upon the form of the narrative analysis (thematic, structural, performative, and visual), characters in a narrative have varying degrees of importance. The other understanding of character as the overall tone of the narration tends to be more in line with an understanding of forms and genres.

## CHICAGO SCHOOL

---

What has become known as the Chicago School of sociology refers to the majority of those working between 1918 and 1965 in the Department of Sociology of the University of Chicago. Inspired by writings on social interaction, especially of those Wilhelm Dilthey and George H. Mead, the Chicago School eventually focused on case study and its analysis by analytic induction, later derived as *grounded theory*. The Chicago School pioneered the case study method, illuminating the social instance by detail of the particular.

### Conceptual Overview and Discussion

By 1920 the case study method and its data analysis were established in the graduate department of sociology of the University of Chicago. The pioneering and founding work, *The Polish Peasant in Europe and America*, by William Thomas and Florian Znaniecki, contributed to the epistemology and methodology of the case study method. First published between 1918 and 1920 as five volumes, *Polish Peasant* is set around the exchange of letters between Poland and the United States of families of new immigrants along with case records of the lives and living conditions of Polish immigrants written by U.S. assistance agencies.

The coverage details explicit issues of adjustment to leaving Poland and being in the United States. Znaniecki, whom Thomas had met in Warsaw in 1913, talked in Polish to many members of the families to seek corroboration of detail. He is credited as the author of the methodological sections of the *Polish Peasant*. Znaniecki argued that research aspiring to application must work on special social problems, following the problem in a certain limited number of concrete social groups, studying it in every group with regard to the particular form under the influence of the conditions

prevailing in this society. This, as Chicagoan Ernest Burgess observed, was the actual introduction of the case study as method.

However, Znaniecki and Thomas attested during discussion at a meeting organized in 1937 by Herbert Blumer that the theory stated in the *Polish Peasant* and written after the field work was insufficiently grounded in the data. During the discussion, which was fully transcribed, Thomas said that the behavior document, whether autobiographical, case record, or psychoanalytic exploration, is a more or less systematic record of individual experience, and the claim for the document is that the extensive record of comparison will reveal the general schematization of individual life. Thomas collected about 8,000 items for use in the study, and the authors provided a historical context for the study.

#### *William Thomas*

William Thomas, who earned his doctorate in sociology at Chicago, and in 1894 was appointed to the faculty, 2 years after the establishment of the graduate department. Visiting Germany during postdoctoral studies in literature, Thomas found that his interpretive, comparative, relative position on literature was similar to the reflexive sociology of Wilhelm Dilthey, whom he met, and Georg Simmel. It is to be noted that with few exceptions (e.g., Aldous Huxley, Franz Boas, Wilhelm Dilthey, Georg Simmel), the human sciences were dominated by measurement, experimental “proof,” and social Darwinism. Dilthey argued that the natural sciences systemize their data by moving toward the abstract, seeking the kind of relation that can be put into an equation, whereas the human sciences systematize by seeing the particular fact more and more fully in its context among other facts structurally related to it. These observations remain relevant to case study.

The University of Chicago, despite its Baptist foundation, was not determinist, but broad in outlook. John Dewey and George Mead were also appointed to the faculty in 1894, and the latter was especially influential, with Thomas, in the formation of the epistemology of what is nowadays often called the School. The department always included people who focused on measurement, and some like W. F. Ogburn (Chicago

1927–1952) were especially oppositional to what was by about 1920 called the case study method.

Fine-detailed descriptive realist narratives had been written before the *Polish Peasant* by Jack London, who was demure about his celebration as a sociologist. *The Road* (1904) is a fully documented case study of the life of a hobo, against which *The Hobo* (1923) by Nels Andersen, based on his Chicago doctorate, is meager in realist narrative. Both had lived as hobos for more than 4 years; London kept notes, and Andersen went back into the field as a participant observer.

#### *Robert Park*

Subsequent to the *Polish Peasant*, the Chicago School pursued reflective, interpretive research grounded in field work. The subjectivities of researcher and researched were taken into account, guided by extensions of the “I, me, thou” relationships promulgated by Mead and Thomas. Crucial to their protocol for research was the formation of self by interaction with others in detailed social contexts. Thomas, and his spouse Dorothy, who founded systematic social observation, left perforce for the University of California at Berkeley in 1942. He was succeeded on the faculty by senior investigative journalist and sociologist Robert Park, who had studied with Simmel. Park strengthened the field work and life history research and with colleague Ernest Burgess wrote the first U.S. sociology textbook, published in 1921.

Park researched, in part by case study method, the boundary maintenance and sources of conflict between communities of immigrants in Chicago. The street and avenue grid of the rebuilt city provided the demarcation lines. Park considered that many of his sociologist contemporaries were misguided in their attraction to an objective science, for their methods could not go beyond the superficial empirical facts. Park advocated the use of autobiography, letters, case records, fiction, and other items that were pristine rather than already categorized. Developing the work of Simmel, Park considered the field worker as a stranger in networks of affiliation, the details of which were to be discovered if at all possible by methods such as case study, document collection, unstructured interviews, observation, and participant observation.

An outstanding student of Park's, completing his master's degree in 1925, was Willard Waller. Waller constructed case studies following the guidelines suggested by Park. His dissertation on divorce was published as were his related works on dating (courtship) and marriage. He moved his case study focus to the institution of the school, where he described in detail over time the formation and dissolution of social relationships, the structure of the school, and the relationships to the wider community.

In all his research, he pursued the horizontal and the vertical relationships using the evidence from his case studies. His 1932 book *The Sociology of Teaching* has, like his other work, had belated appreciation as pioneering and prescient. Indeed Waller, although deceased age 46, fulfilled much of promise of the methodology of the *Polish Peasant* in work that survives as insightful and stimulating to inquiry.

Park developed the constant comparative method, as advocated by Thomas, in the sifting and inference stages of data analysis. The method is intrinsic to the Chicago case study method and in this sets the School apart from other universities, which began studies of the detail of the particular within explicit boundaries. The method of analysis developed and was later called analytic induction, or the analysis of deviant cases, and is central to "grounded theory." The method is a way of doing hypothesis-deduction and is most explicit in the post-1946 work of Chicagoans, especially Anselm Strauss and Howard S. Becker.

### *Differences in Perspective: Blumer and Hughes*

Herbert Blumer studied with Park and developed the self-other-context relationships of Mead into a social psychology centered on subjective meaningful exchanges: symbolic interaction. Blumer voraciously read the output from the Chicago School: case study, social ecology, social survey, and so on. He was the philosopher critic to all comers. Appointed to the Chicago School in 1932, he was asked to assemble a critique of the *Polish Peasant*. The 1939 publication includes a transcript of the debate by the attendees, who included Thomas, Znaniecki, and Burgess.

When another of Park's students, Everett Hughes, was appointed to the Chicago School faculty in

1938, the friendly antagonism of Blumer provided colleagues and students with a constant comparative second opinion. Hughes advocated involvement in field work up to the neck and then, before drowning, returning to reflect on what had been learned. Blumer was never a field worker, and cautioned colleagues and students on what he considered the atheoretical and perilous forays advocated by Hughes. Between the cautions and forays, the Chicagoans of the 1940s to 1962 produced numerous field work-based case studies that penetrated the masks and mirrors of institutions and careers and role.

After earning his Chicago doctorate in 1928, Hughes completed a major community study of an industrializing town in Quebec stemming directly from the work of his teacher Park and strongly influenced by Simmel. On his appointment to Chicago, Hughes theorized about work and career, and researched these and transitions of role and identity. Hughes, with Park's contemporary Ernest Burgess, taught the compulsory field work course, sustaining a focus on the city of Chicago. Integral to the course was the allocation of a census tract to various student pairs, each being told to collect data about their assigned plot. Thus students were thrown into field work "on the hoof," as Hughes called it. Each course required a research paper, not an exam.

## Application

### *The Third Generation*

In 1955, Hughes in collaboration with Strauss, Becker, and Geer began the study of the socialization of medical students at the University of Kansas. Hughes was the director based in Chicago; most of the field work and writing was done by Becker, who was resident in Kansas City, and Strauss, along with Blanche Geer. *Boys in White: Student Culture in Medical School* displays the power and subtlety of the case study method; indeed it comprises many case studies. The data were assembled from participant observation of all phases of the "rite de passage," from documents, interviews, and so-called casual remarks. The researchers pursued apparent discrepancies and lacunae in the data in the process of its collection. No data were discarded, for all hypotheses were heuristic rather than firm during the process of the field work.

Toward the end of the field work, the researchers had a sufficient level of confidence that they were able to describe the processes of induction into professional medicine. This process was rich with conflicting demands and expectations of faculty as compared to students, whose ideals about medical practice were challenged, even overcome by the mundane yet priority demand of medicine under pressure of time and urgency. *Boys in White* and the subsequent study by the same collaborators on the consequences of graded testing in university, *Making the Grade*, are outstanding examples of interpretive field work forming case studies. Other notable case studies based on the deviant case analysis include *Timetables* by Julius Roth, *Goldbricking* by Donald Roy, and *The Urban Villagers* by Herbert Gans. Ervin Goffman's work was more orientated to illustrating and establishing theories. In *Timetables*, Roth began case studies of a TB hospital, whence he contracted TB and completed the studies from the perspective of a patient.

Anselm Strauss (Chicago 1952–1958) was appointed after his graduate studies in the department, as Blumer was leaving. Strauss understood the qualitative, interpretive, quantitative, and demographic and was also a field worker, methodologist, and theorist. In the 1960s he researched institutional social relationships in psychiatric hospitals where case studies detailed the shifting role and identities of both patients and staff. In a subsequent study, with Barney Glaser, of a terminal cancer ward, the case studies raised many questions about how staff conducted themselves in providing more or less information to the patient to raise or attenuate awareness of dying.

Strauss was keenly aware of the gap between theory and research as identified by Blumer, and published extensively on the epistemology and logic of interactionist research, discussing case method, which he considered synonymous with case study. His book *Qualitative Analysis for Social Scientists* is invaluable not only for its methodological content regarding constant comparison but also for setting that analysis in the wider context of qualitative and statistical methodologies.

Howard S. Becker completed all his degrees at Chicago, commencing in 1943 and completing his doctorate, on Chicago schoolteachers, with Hughes, in 1951. During the late 1940s, as a pianist, he

used participant observation to study the perspectives of dance band musicians, this becoming his master's thesis. Written mostly as narratives about the musicians, his work includes many case studies framed by a symbolic interactionist and reflexive theory. The same is true of his *Becoming a Marijuana User*, which details how the user learns to appreciate the special qualities of marijuana from sessions with experienced smokers. Through a career spanning 60 years, Becker sustained and further developed through his creativity the research of the Chicago School. His 1982 *Art Worlds* is about the political economy of the visual art market, rich with detail of the particular woven into a descriptive theory, iterating cases.

Becker took part in a 1975 conference in the United Kingdom on the use of case study in evaluation and educational research (*The Science of the Singular*, 1980) and integrated past and present understanding subsequently through meetings of 1988 and 1989, leading to the book, *What Is a Case?* (1992). Becker's chapter succinctly reiterates the main issues and extends these to related problems of present and future case study research. Having considered the worth of correlational and conjunctural analysis of cases, Becker takes up his position, which elaborates the centrality of developing imagery for research, this being propounded by Blumer. Becker concludes,

Narrative styles of analysis devote a lot of time and energy to developing this imagery, which is another way of talking about the analysis of the dependent variable. Developing imagery is a process in which we try to understand what we want to understand better. We do not search for causes so much as look for stories that explain what it is and how it got that way. When an analyst of causes has done the job well, the result is a large proportion of variance explained. When an analyst of narrative has done the job well, the result is a story that explains why it is inevitable that this process led to this result. (p. 212)

### Critical Summary

In *What Is a Case?*, Andrew Abbott, currently professor at the University of Chicago, reconsiders the influence of Park and his students. For Park, concludes Abbott, causal analysis was secondary

to description, or narrative. Park encouraged the seeking of “universal narratives” such as those that reiterate the stages of development toward, for instance, delinquent behavior, revolution, industrial crisis, and occupational orientation, this latter being by far the dominant area of Chicago case study. Abbott ends his chapter with a plea to policymakers and social scientists to consider narrative case study as much or more than population-variable studies, as the former would disclose more of the causes of organizational perturbation. The innovative work of the Chicago School, exemplified in the work of Becker and of Strauss, continues to stimulate and be emulated by those struggling with case study.

## CHRONOLOGICAL ORDER

---

Chronological order applies to case study research in several ways and refers to the sequencing of events as they successively occur or have occurred. Simple ordering by such measures as date and time of day allows events to be presented and considered in a sequential, systematic, and organized manner.

#### Conceptual Overview and Discussion

Chronological time and, by implication, chronological order are to a large extent culturally dependent. In agrarian or aboriginal cultures and in some belief systems where time (and thus order) is reckoned as seasonal, cyclical, or generational, the chronological construct is less useful for grasping meanings of time as it is experienced by members of that culture. Some indigenous cultures (e.g., Hopi Indians) hold the view that all events are in present time and have no conceptual use for past or future dimensions. In such situations the *what* of an event is of greater importance for that individual or group of individuals than the *when* of the event. Accounting for such conceptions in case study research means acknowledging the representation as one way of providing context that is external to the event and may not fit with individual depictions held by researchers unfamiliar with cultural variations.

Chronological ordering is a device for imposing structure in ways that attend to sequence and duration as might be perceived and measured through inquiry of some sort directed by the topic and issues of interest. Clocks and chronological time are fairly recent developments, used in early days as assistive devices for summoning the religious to worship, workers to industry, and as a navigational aid. The division of time into zones

and yearly units into months, weeks, days, hours, minutes, and seconds has acted in fundamental ways that facilitate communication, commerce, and social cohesion around the globe.

### Application

Consideration of the temporal domain in case study research applies beyond data arrangement and pertains to the researcher and sequencing of materials and methods used to gather data as well as ordering of data presentation in the research report. Chronological order is also known as natural order, as one event must precede or follow another event unless they occur simultaneously. Considering events in order of occurrence is a familiar device for organization such as can be found in stories that have a beginning, middle, and end, such as case studies presented in a narrative format.

Composition of a constructed story line depends on how the author chronologically organizes her or his procedures in order of processes and that guide inquiry. An inductive approach might derive from an existing framework imposing guidelines for the development of specific understandings, assumptions, and questions. A more deductive approach might consider events an issue for discovery of themes or central problematics, which then guide ordering and sequencing of subsequent steps, which may or may not be in chronological order. Order of encounter with issues as presented in research may thus cause different conceptions than issues first encountered in practice.

During initial problem development, the order in which related research is encountered may lead to or away from certain predispositions or attitudes toward the question or issue under examination. For example, a study of reading patterns may take a different turn if the author considers materials addressing matters of race, class, and gender prior to, or following, problem and question formulation. Topic and timing in the sequencing of questions or discovery of materials can predispose patterns of response or analysis visible as meaning-making occurs during data analysis. Interviewer skills also increase over time as familiarity and comfort with procedures grow. Transcripts may show the effects of chronological time and experience as a tenth interview is usually of higher quality and more insightful than a first interview.

Following a chronological order in the elicitation of information, events, and meanings provides a chronicle of events organized by a time line. Temporal arrangement of events creates context from which meaning(s) can be derived depending on other events that occurred before, simultaneously with, or after the event in question. Relationships between events can be considered as cause, consequence, or coincidence based on chronological order or timing. Causal (X caused Y) or logical (X caused Y in ways that cannot be measured) relationships depend on chronological order and assume that X must precede Y, otherwise Y would not have occurred, and if Y did occur anyway, then something else caused it.

Sequence of collection may be different from the sequence imposed on events when arranged for reporting. Unless chronological order is rigorously imposed by an interviewer (which may cause a loss of valuable information), a participant's sequencing of recalled events, opinions, or ideas may show memory paths or an ordering of events in terms of a psychological time frame that draws experiences and perceptions together by like feelings or emotive content rather than the *when* of occurrence. Inventories of events, whether labeled by time or the nature of the episode, can assist the subsequent development of domains, taxonomies, components, and themes for reporting that capture the experience for the reader.

Chronological order is useful if not necessary for coherence when multiple accounts or participants are considered in context. Placement of cases or situations relative to each other in terms of actual occurrence can be used for verification or for purposes of contrast or comparison and can provide a context for simultaneous occurrences in other domains or cases. The conceptual calibration afforded by chronological ordering can assist critical assessment of balance between the beginning and ending of accounts by reversing their order.

Reverse chronological ordering is a technique sometimes used to ensure that history or background, whether of a client or research participant, does not outweigh current status or responses to investigative questions. Reverse ordering may also reveal relational aspects of events less visible when otherwise examined. Planned order may thus be revised as emergent themes cause reordering when contrasted with the order of necessity afforded by

linear representations of time, whether forward or backward.

In collaborative research, more than one researcher and participant are usually involved and need to account for cross-event comparisons based on simultaneity. Chronological time or scenario-based time can facilitate understanding occurrences when viewed forward and backward as more balanced attention is paid across and within the beginning, interactive, and current status of investigative relations to the problems and participants at hand. Annotations of meaning in the form of links that transcend chronological ordering may assist larger understandings. Such approaches involve hermeneutical and phenomenological approaches that identify themes across and within stories and tellers. Data sources such as might be used to provide triangulation may be more robust when linked or associated by chronological ordering.

Chronological order can play a role in research as a long-term or short-term measuring stick. Daniel Levinson's *Seasons of a Man's Life* (1978) and *Seasons of a Woman's Life* (1996) covered significant portions of the life course of selected groups for many years. Studies of shorter duration include Rebecca Reiff's *A Day in the Life of a Student Teacher*.

Chronological ordering is also used for the development of sequence in chapter formulation for research reports. Communication of the process, content, and findings of a research study need to be presented in a systematic way that is intelligible and logical for the reader. Thus in the standard five-chapter format used in many reports (problem statement, related research, methods, findings, and conclusions), steps logically follow each other in both conceptual and temporal frames as each stage is dependent on matters addressed in the previous one.

### Critical Summary

Chronological order and its companions, time, timing, and duration, are research tools that facilitate precision in communication of events. Attention to the expectations of such accounting methods in certain types of research is important for adherence to methodological consistency. However, alternatives to chronological order (e.g.,

psychological or seasonal) that require stepping off a time line may add details and richness to a study and acknowledge cultural and conceptual variations in the representations of events.

## CLASS ANALYSIS

---

Class analysis is a theoretical approach in the social sciences. It explores the determinants and consequences of social phenomena in terms of class and class relations. Class analysis views society as being divided into hierarchical strata that have unequal access to material resources, power, and influence. It is based on the premise that class systematically and significantly impacts the lives of individuals, the dynamics of institutions, or the patterns of social change.

### Conceptual Overview and Discussion

Class analysis can be conducted at either the microlevel or the macrolevel. The microlevel class analysis explores the ways in which individuals' class locations determine their well-being, beliefs,

and behavior (e.g., voting behavior, ideology, and offspring's educational attainment). The macrolevel class analysis focuses on the effects of class structure or class relations on a variety of institutions and trajectories of history (e.g., how variations in class structure across time or space, such as the decline of the industrial working class, affect the type of state or political regime).

Although class analysis has figured prominently in a great deal of social science research, the word *class*, which is pivotal in any class analysis, is one of the most contested concepts in the social sciences. There are varieties of class analysis; and these varieties are grounded in different understandings of what class is and contesting approaches to how best one can identify and/or measure different classes. The main distinction is between the gradational and relational notions of class.

In the gradational notion, class is used to describe a set of layers or strata in a hierarchy. These strata are generally distinguished on the basis of inequalities in material conditions such as income or wealth, as in the terms of upper class, middle class, and lower class. But they do not stand in any systematic social relationship to each other. Thus the gradational class concept does not entail any notion of systematic relations among defined classes. Social science research that is primarily interested in the statistical correlation of income and wealth with various social outcomes mostly uses a gradational definition of class.

In the relational conception of class, classes are defined in relationship to other classes. Given classes are internally related; that is, they are defined on the basis of the social relations that connect them to each other. The interests of a particular class are a function of the relations that bind it to other classes. The relational approach to class is interested in the causal mechanisms that produce socioeconomic inequalities as well as class as a collective actor that pursues its interests.

### Application

There are, however, different traditions of class analysis that adopt a relational notion of class. The two most influential are the Marxian and Weberian traditions. Karl Marx was the first to develop a systematic theory of class, and his theory greatly influenced how the concept of class analysis has

been developed and used. According to Marxist scholars, production relations (who produces what, how, and for whom) are the most important of all social relations. The relations of production form the material basis of classes. Individuals who occupy similar positions in the production relations objectively belong to the same class. Classes are defined by the relationships of exploitation. Therefore, class relations are inherently contradictory and antagonistic, not only in terms of income or wealth distribution but also and more importantly in terms of production relations.

In capitalist societies, the working class and the capitalist class are the fundamental classes; and the key dynamic feature of capitalism is the exploitation of workers by capitalists. Marxist class analysis puts the emphasis on exploitation and antagonistic interests. Class is at the center of social change because of the conflicts antagonistic class interests create. Thus Marxist class analysis embodies a theory of historical change.

Marxist class analysis has three main elements that form the subjective and objective existence of class. The first element is class structure, which is the totality of objective class positions that make up a society. The second and third elements are class formation and class struggle. Class formation refers to the process of an objectively given class becoming aware of itself and its interests in relation to other classes and its organizing into a collective actor. A social class as a collective actor engages in a variety of practices to defend its interests in opposition to other classes, thus creating class struggles. Marxist class analysis has been criticized for its failure to account for the middle class in capitalist societies. Critics argue that professionals and white-collar employees do not easily fit into the Marxist analysis of class because they are neither working class nor capitalists.

Like Marxist theory, the Weberian approach to class analysis—based on the work of Max Weber—also has a relational notion of class. Unlike the Marxist approach, the Weberian notion of class focuses on exchange or market relations rather than production relations. It assumes no inherent, irresolvable conflicts of interest between classes. The hallmark of the Weberian approach is its view of the multidimensionality of social stratification. While class is an important determinant of the social hierarchy in modern society, it is not the

only factor. A variety of other factors, including authority, prestige, and occupation, play an important role in creating social divisions. Modern society is divided into many status groups that are determined by prestige and lifestyles, and that are distinct from social classes.

There are numerous case studies on a wide variety of subjects that employ class analysis. One of the major subjects for such studies is the class character of state institutions and policies in particular countries or political systems. A good example is Leo Panitch and Donald Swartz's study of the Canadian state's trade union policy. Many such studies investigate whether or to what extent the state is independent of the dominant class in society. The most influential of such class analyses of state autonomy include the work of Ralph Miliband, Nicos Poulantzas, Goran Therborn, and Bob Jessop. Gosta Esping-Andersen and Walter Korpi have conducted case studies of the welfare state in industrialized countries from a class analysis perspective. They explain the differences between countries in the historical development and type of the welfare state in terms of the class power of labor relative to other social classes.

During the past two decades, the relevance of the concept of class and of class analysis has been intensely debated. The downfall of communism and the loss of appeal of Marxism as a political project fueled arguments about the failure of class analysis. Although not all class analyses are Marxist, the class concept occupied a significant place in social science research during the 20th century to a significant extent due to the intellectual and political influence of Marxism. The decline of the influence of Marxism has been accompanied by a variety of arguments about the increasingly problematic nature of class-based explanations as well as the declining political relevance of class. Some commentators have argued that as a result of the major changes in employment relations, such as casualization of employment, decline of blue-collar industrial jobs, growth of service sector occupations, and hence increasing individuation in employment relations in recent decades, class no longer forms the bases for identities and collective action. Ethnicity, gender, or value commitment often now provides the referents for identity and political activism that once flowed from class.

Critiques of class analysis have also argued that the important conflicts and cleavages of contemporary society are not class based; they revolve around nonclass issues such as gender inequality, minority rights, and the environment. For some critiques, class analysis is inadequate as an explanatory framework for contemporary society because personal lives are increasingly autonomized as a result of the spread of the culture of consumerism.

### Critical Summary

There have been two broad responses to the criticism of the failure of class analysis. The first response is to abandon the previously influential approaches to class analysis in favor of new approaches. Many of those who made a case for a new approach to class have been influenced by postmodern theory. They reject a single meta-narrative of class and call for a pluralistic approach that reflects the diversity of culture and identity. Some have developed an explanatory framework that emphasizes the interdependence of the different social categories of class, gender, and ethnicity or race without assuming the primacy of class a priori. It is argued that class, gender, and ethnicity are internally linked and that systematic inequalities associated with any of these social categories are systematically related. That is, they can be understood only in relation to one another but without reducing them to any one category. These postmodernist inspired approaches to class and social stratification place more emphasis on ideational and discursive practices than material factors in explaining systematic inequalities and oppression in society.

The second response to the crisis of class analysis is to refine or revise the earlier major theories of class, mostly Marxian and Weberian, in order to address their inadequacies in view of the extensive transformations that have occurred in the spheres of production, market, and consumption on both the domestic and international scales. Unlike the first strategy, the second strategy remains committed to developing a comprehensive framework of concepts and methodology for the analysis of class and stratification. It is based on the conviction that it is possible and desirable analytically to separate class from other social categories while recognizing that they are combined in concrete situations.

Some scholars have recently pursued one of the two strategies in revising existing major approaches to class analysis to better reflect contemporary conditions. One strategy is to extend class analysis to the global or transnational level in recognition of the fact that national societies and economies are increasingly interconnected as a result of globalization. Until recently, class analysis, whether Marxist or non-Marxist, had taken national society as the primary unit of analysis. A growing number of class analysts have started to explore the emergence of classes and class relations that cut across countries. These class analyses have focused mostly on the formation of a transnational capitalist class as a result of the growing weight of transnational corporations and foreign direct investment.

The second strategy is to refine or add class positions within the framework of an existing class theory. Some Marxist class analysts, for example, have tackled the problem of how to accommodate middle-class professionals and new service employees within the Marxist class analysis that designates classes on the basis of exploitation in the production process. These efforts often involved borrowing concepts from the Weberian approach, such as authority, autonomy, and credentials. In conclusion, there have been significant efforts to reformulate and reinvigorate class analysis in response to its recent crisis.

## CLOSURE

---

Closure signifies that an event or series of events have occurred and reached an end or an end stage when planned or anticipated finalization or disengagement has or ought to have occurred. Closure implies resolution of matters associated with an event to the extent that individuals associated with the experience in question can move forward with a sense of conclusion and end.

### Conceptual Overview and Discussion

Closure is a process with conceptual gradients attached to companion terms *duration*, *ending*, and *resolution*. By way of example, sporting events conclude when marked by the bell or whistle that signifies duration limit and the end of the event. Outcomes are determined by such rules or criteria that govern the activity, and resolutions or scores are entered into an official record under the appropriate statistical or outcome category. Once that event has terminated and the factual aspects of it are transformed into a data set, additional aspects of process may occur regarding incidents during the contest and stand as mythologized markers of the event. Depending on whether the contest was carried out with good or poor sportsmanship, fairly refereed or judged, replete with distinguishing behaviors or accomplishments (or lack thereof), and if the event carried large significance, for example, The World Cup of Soccer, resolution may not occur in spite of duration limit and end of contest. Residual markers of feats and follies as might be discussed at the next match would indicate that full closure is no more possible than full objectivity, as related events may invoke memory traces that open the event for reconsideration and reconstruction,

such as new contexts for discussion and meaning-making provide.

Closure in case study research is more complicated than sporting events as the personal stakes of psychological well-being are involved. Research questions developed for use in case studies that take advantage of the variety of available methods are intended to introduce a topic or question for the purposes of eliciting a truthful, meaningful, and significant response that can be used to elaborate or buttress findings later on. Questions about soccer games may evoke a set of responses basically contained within the respondent's constellation of constructs pertaining to soccer. It would make a large difference if the respondent were a fan, or a member of the team primarily responsible for winning (or losing) the contest. Added meaning-value is present dependent on the proximity and level of investment of the participant in questions and issues posed for consideration.

Opinions *of* experiences are different from opinions derived *from* experience as are vantage points of *observers* and *participant observers*. Different forms and depths of psychological motion begin with reflection on experienced events depending on level of impact and potency of derived meaning for the participant. Residual issues arising from questions about a match posed to the fan would likely be transitory and short-lived. The same questions asked of the winning or losing players would carry a greater likelihood of residual effects. The span of intellectual, emotional, physical, and perhaps spiritual connotations and attributions covering the range between victory and defeat is vast and rich with signifiers of meaning and understanding.

### Application

Identifying and isolating a particularly meaningful or loaded event for examination, while compelling from an investigative perspective, carries with it the researcher's responsibility for ensuring closure in ways consistent with the expectations of Ethical Review Boards (Canada) or Institutional Review Boards (United States) and the most reasonable care and consideration for participant welfare. Whether pertaining to losing athletes, victims of violence and abuse, failing students, or burned-out teachers, opening issues with significant impact for

discussion means that additional care, attention, and measures must be in place to ensure adequate closure beyond the duration of the study. While participants do have ownership of their stories and do agree through informed consent to share them through inquiry, safety measures such as termination at any time to facilitate ease of closure must be anticipated when disclosure and discussion of perturbing events is part of, or inadvertently becomes part of the research process. Significant authentic engagement by the participant is an indication that extraordinary opportunities for closure may need to be in place. Closure may also require a physical or symbolic component such as publication and acknowledged co-construction of a meaningful account laden with meaning and learning.

Ross and Wright consider closure as it might be reached in simulations for training purposes and agree that it is a complex and multifaceted area that merits special consideration in that context. Such issues can only be of more vital consideration in real-life research. Equally important are symbolic closures such as destruction of transcripts or story pages as a way of acknowledging catharsis, control, and closure. Engagement with any participant on any question must ensure that appropriate checks are in place to bring about such reasonable closure as is possible in the circumstances of the research. Follow-up as promised (e.g., sharing findings or publication) and follow-up as dictated by respect for participation are essential and may in some cases prove more insightful than initial research findings.

### Critical Summary

Closure, while desirable from a research perspective for both participants and researchers, may not be possible in its fullest sense. Self-declared closure may be the best that can be expected from research participants and must be accepted at face value by the researcher unless other problematic indications arise. Closure may be difficult to reach since requisite conditions may be as complex as the variety of issues of interest to researchers.

## CODIFYING SOCIAL PRACTICES

---

Codifying social practices amounts to embarking on a process of transforming practical knowledge—knowing in action—into a message that can be processed as information. Today the social sciences, especially management, are interested in actors' practices and the progression of those practices. This new kind of research implies new kinds of investigation. Thus, qualitative methodologies have to consider not only how people tell about their practices, but also knowledge that is performed. Those undertaking case study research will inevitably encounter knowledge that is practical (tacit) and will face the task of codifying that knowledge.

After a brief overview of the sense that codifying social practices has acquired in the development of our societies, and its challenges within a knowledge-based economy, this entry then examines it within the framework of two extreme forms taken by knowledge management. It then examines the complex question of the tacit nature of practical knowledge—knowing in action—and finally the spontaneous and scientific methodological approaches designed to explain it.

### Conceptual Overview and Discussion

#### *History and Challenges of Codifying of Social Practices*

The codification of social practices begins with writing. According to Jack Goody, this operation

expresses broadly a society's will to make up for the weaknesses and uncertainties of human memory with the aim of storing knowledge, perceived as a learning program. But writing also has cognitive effects on society, by developing abstraction capacities and the critical function, which play a specific role in encouraging new knowledge production. This operation takes on a particular value today, according to Dominique Foray, in relation to the emergence of a knowledge-based economy. In effect, the key factors for the success of companies and national economies are more than ever dependent on their capacities to produce and use knowledge. Since the main source of this knowledge is tacit, the problem of codification becomes vital in economic terms. In effect, codification makes it possible to detach knowledge from the person who possesses it. It involves a fixed cost—that of expressing the knowledge in a language and recording it on some form of support (e.g., paper, databases)—but then increases the efficiency of a whole series of knowledge management operations: memorization, distribution, learning. Once a formula has been written, which may represent a significant fixed cost, it may then be communicated broadly at a negligible marginal cost. In the management field, Ikujiro Nonaka and Hirotaka Takeuchi have identified a key stage in the spiral of organizational knowledge creation, the spearhead of Japanese company performance: the stage known as externalization. It consists of the passage from tacit knowing to explicit knowledge. The codification of tacit knowing has become a challenge for both economists and managers—even as it is for researchers. It is a complex operation, due to the very nature of tacit knowing, which still seems impossible to reduce to a codification operation. In addition, the codification process can never supply all the knowledge necessary to undertake an action.

In pragmatic terms, companies that have undertaken knowledge management have found this problem a stumbling block at some point in the process. It arises in different ways, depending on the strategy implemented. Morten T. Hansen, Nitin Nohria, and Thomas Tierney have identified two key ways of envisaging knowledge management by organizations: Organizations operate with two different knowledge management strategies, namely a codification strategy where knowledge is

codified and stored in databases, and a personalization strategy where personal interaction is essential. These two forms of knowledge management reflect different visions of the organization—on one side, the paradigm of Herbert Simon’s information processing system; and on the other, the community of practice of Jean Lave and Etienne C. Wenger. On one side there is a cognitivist vision, in information system terms, of knowledge management: It is the image of a physical platform for storage of information; on the other is a communitarist vision, in terms of management of human resources, of knowledge management: It is the image of the social network. The codification operation is as essential to the first strategy as it is negligible or even nonexistent in the second. Rather than completely contrasting these two forms of management, many authors try to combine them. We may well ask whether we are not actually in the presence of two socio-technical configurations, as defined by Bruno Latour, that we must describe effectively: What is a data warehouse without the people who use it? What is a social network that operates without any physical support? The operation of codification takes different forms, depending on the socio-technical pairing modes applied. Subsequently, we can envisage within a community of practice where there is mentoring between an expert and a novice, which is based, at a given moment in time, on the expert’s expression of his practice, taking the form of a written discourse that the novice will use as a support within the framework of his learning. To tackle the question of codification from a methodological point of view, we must examine the nature of tacit knowing.

### *Nature and Foundations of Tacit Knowing*

The universally recognized authority in any discussion of tacit knowing is Michael Polanyi. He puts forward the argument that there are things that we know but cannot tell. This is strikingly true for our knowledge of skills. He takes the example of swimming. We can say that we know how to swim, but this does not mean that we can tell how we manage to keep afloat when swimming, or how we coordinate the complex pattern of muscular acts by which we do our swimming. In the same way, in an everyday situation, we can easily recognize a familiar face, but we are incapable of identifying

how we do so. This shows that a simple action often reveals a far greater skill than we would have believed, and we are generally unable to describe the knowledge revealed by our action. The knowledge that we mobilize in practice is not the result of conscious learning: It is implicit knowledge, or tacit knowing, that is, related to knowing in action. In a similar vein, Donald Schön addresses the knowledge put into practice by professionals (teachers, town planners, managers, etc.) in exercising their activities. These different works converge in their thinking. They show that the practical knowledge mobilized by a subject in a situation is first of great value, and next that it is not directly accessible, meaning that it is implicit and not conscious. A long time before these works were conducted, psychologist Jean Piaget also reached a similar type of conclusion, in the 1970s. In effect, he looked at the question of the consciousness of subjects while conducting practical operations. Straightaway, he identified the fact that action in a situation is autonomous knowledge that remains largely unconscious. We can successfully complete an operation that is the positive sanction of a certain practice, but not understand it. Understanding, which is the literal meaning of conceptualization, supposes an effort of abstraction to a greater or lesser degree, depending on the subjects concerned.

### **Application**

On this basis, psychologists such as Pierre Vermersch have explored the possibilities of articulating lived experience. From a phenomenological psychology point of view, he examines the tacit nature of knowing in action. Lived experience is not immediately accessible, for it is largely implicit in the sense of being prereflective. That is, it has not been made an object of consciousness, although this is possible. In support of his theory, he uses the distinction made by Piaget between reflecting activity, the act consisting of becoming conscious of lived experience, and meta-reflection, the act consisting of analyzing information already brought to consciousness. Vermersch constructed a device, the explicitation interview, to access this source of information on action: that which can be brought into consciousness, corresponding to the stage of reflecting activity and not the stage of reflection on lived experience.

Schön develops another method to access the hidden knowledge underlying professional action: “reflection on the reflection in action.” In this way, he suggests following the process: (a) observation of the action, (b) recording of the action, (c) reflection on recording of the action, (d) description of the action, and (e) reflection on description of the action. Jerome Bruner demonstrated that the spontaneous narrative structure—a story—is essential for the transmission of human experience. This story always begins with a description of a usual setting (arena, actors, what happens . . . ): It introduces normal things. Then, an unexpected event, a *péripétéia*, happens that modifies the course of the story and its ending. There is always a moral, but it is more suggested than formulated. This is a spontaneous way to codify and to hand down social practices.

### Critical Summary

Many devices have been developed, either from practical knowledge or science, in response to this problem of codification of social practices. Vermersch provides the explicitation interview. Bruner demonstrates the value of spontaneous narrative structure. Schön points out the possibilities of reflection on the reflection in action. We must also note organizational practices in terms of feedback, analysis of work centers, implementation of quality standards, and so forth. In scientific terms, work psychologists and ergonomists, in the main, have built tools for the investigation of individual activity, which undeniably provide access to extremely valuable information. Progress has also been made in terms of investigation of collective practices, mainly by anthropologists. But as things stand at present, the question of articulation between these two perspectives, that is, to study at the same time both individual and collective practices, remains unanswered.

## CODING: AXIAL CODING

---

Axial coding is the process of relating categories to their subcategories. Anselm Strauss and Juliet Corbin used this term in *Basics of Qualitative Research* as one of the data analysis techniques by which grounded theory can be performed. The essence of axial coding is to identify some central characteristic or phenomenon (the axis) around which differences in properties or dimensions exist. Axial coding is therefore a process of reassembling or disaggregating data in a way that draws attention to the relationships between and within categories.

### Conceptual Overview and Discussion

Any exploratory research that is interested in developing theory has to deal with the interpretation of data in ways that specify the concepts of interest, causal relationships, the presence and effect of contextual relationships, and outcomes. Exploratory research usually relies heavily on qualitative research methods because they are particularly well suited to the exploration of patterns in data that are not guided by a priori expectations or constrained by the operationalization of complex phenomena. Case study research is often used in an exploratory way, looking at a single individual, organization, phenomenon, or event with the aim of understanding its complexity in as complete a way as possible. Doing so usually involves the collection of many different types of data, all

of which need to be systematically analyzed in a way that identifies the specific concepts that are at play, and how they relate to each other to produce a certain outcome. Axial coding is one technique by which this analysis can be performed.

Strauss and Corbin describe several coding techniques particularly well suited to grounded theory research, that which generates theory derived from data in a systematic and rigorous way. At the heart of any theory is a set of concepts, the presence of which allows for the concepts to be studied in ways that generate propositions or hypotheses concerning the way they are related to each other. “Coding” is the label Strauss and Corbin use to describe qualitative data analysis as it pertains to the discovery of concepts and their relationship to other concepts. “Open coding” describes the process by which concepts are identified and their properties or dimensions discovered. Concepts are therefore the building blocks of theory.

Coding of this type needs to examine data in a conceptual way in order to identify what objects, actions, or events are present and are of theoretical interest. Often the process of open coding produces many concepts that can subsequently be grouped into categories based on something they have in common in a way that is important to what is being studied. Once a category has been identified, it becomes easier to develop in terms of its properties and to break down further into subcategories based on the particulars (when, where, why, and how) that are present in the data.

“Axial coding” is the process of relating categories to their subcategories, the outcomes of open coding. The term *axial* comes from the axis of a category, its properties and dimensions. Strauss and Corbin describe the basic tasks of axial coding as follows:

1. Identifying the properties of a category and their dimensions. This process usually begins during open coding, when categories (something significant to respondents) and subcategories (answers to questions about categories) are first identified.
2. Identifying the conditions, interactions, and consequences associated with a phenomenon. These form a paradigm, or perspective taken toward data. This allows the researcher to code for explanations and to gain understanding of a phenomenon’s complexity.
3. Understanding the relationship between a category and its subcategories. How these relate to each other is the basis for hypotheses or propositions because they link concepts together, explaining the particular manifestations of a phenomenon.
4. Searching data for ways in which categories might relate to each other. This allows for the emergence of novel relationships that may have previously gone unnoticed.

### Application

The case of the Westray mine explosion in Nova Scotia, Canada, was used to study institutional influences on workplace safety. The article “Institutionalized Mindsets of Invulnerability: Differentiated Institutional Fields and the Antecedents of Organizational Crisis” used the techniques of grounded theory to understand how organization crisis occurred in a highly regulated industry with very predictable (albeit serious) safety risks. This study was interested in identifying the antecedents of organizational crisis in an organizational context of heavy regulation and established production technology. It therefore started with an outcome (an underground mine explosion) and examined its institutional antecedents.

The first major category identified in data analysis was institutional influence, established by the literature as an important factor in determining workplace behaviors. This category was later divided into three subcategories based on the different institutional logics in play, each of which took particular forms in the day-to-day work lives of the underground miners. During this process of coding another category was identified—perceptions of risk—that was related to the organizational practices and contextual characteristics present in the organization and its environment. These two categories were shown to be mediated by an attitude referred to as a “mindset of invulnerability” that explained the relationship between the two categories and made sense of an organizational crisis that was entirely preventable.

More specifically, the process of open coding identified micro-institutional processes as a major category. Subcategories were later created as different institutional logics (i.e., instrumentality, appropriateness, and orthodoxy) were identified in the

larger category of institutional influence. For example, a logic of instrumentality was at the root of regulative processes that guided individual behavior in an coercive way. Further specification of this subcategory identified three constructs that were manifestations of this type of institutional influence: (1) the illusion of regulatory protection, (2) peer pressure, and (3) intimidation/harassment.

Axial coding was the process that revealed the centrality of institutional logic in this category, as well as the relationship between it and the emergent category labeled perceptions of risk. The resulting model showed how organizational crisis was due in large part to a mind-set of invulnerability that resulted from a compounding set of institutional pressures, none of which on their own would likely have resulted in crisis.

### Critical Summary

The process of data analysis is central to the reliability and validity of all research. Strauss and Corbin use the term *coding* to refer to data analysis, the process by which labels and meaning are attached to data that are observed. Qualitative research is centrally concerned with providing compelling arguments concerning what is going on and what significance it has for the world around us. The process of coding is a careful examination of data (e.g., interview transcripts, observations, media reports, memos) with the purpose of interpreting them in meaningful ways. Open coding that identifies categories and subcategories, combined with axial coding that identifies the relationship between and within categories, combine to form a rigorous approach to qualitative data analysis that allows the possibility of revealing new concepts and novel relationships that allow for the refinement and development of theory.

## CODING: OPEN CODING

---

Open coding is an essential methodological tool for qualitative data analysis that was introduced in grounded theory research. *Open coding* refers to the initial interpretive process by which raw research data are first systematically analyzed and categorized.

### Conceptual Overview and Discussion

Barney Glaser and Anselm Strauss were among the first to formally introduce the procedure of open coding in their seminal work, *The Discovery of Grounded Theory*. In this study of the behavioral patterns of hospital workers and dying patients, Glaser and Strauss modeled how intuitive and inductive researchers must be personally and actively involved in the coding of field data in aid of theory development. Open coding is the process through which “grounded” researchers initially begin the process of questioning, reflecting upon, and categorizing the actions, perspectives, and words of the actors in their study through their raw research data. Open coding is the initial data work that builds from the ground up, by identifying essential concepts and patterns that emerge in vivo from an initial, yet rigorous open reading and reflection upon raw data.

In grounded theory research, open coding is one of the three types of coding that are used progressively: open, axial, and selective coding. Open coding is the initial intensive interplay of an interpretive or interrogatory and often intuitive process between researcher and data by which the raw data, including words, phrases, events, or actions, are broken down, taken apart, or analyzed for their potential or relevance to the identification and conceptualization of phenomena that emerge from collected data. In open coding, concepts, the most basic unit of analysis, are identified from distinct events, incidents, words, or phrases in the data and are given conceptual labels or identifiers. Events, actions,

and interactions are grouped together to form categories and subcategories. Each category represents a unit of information with properties that can then be examined against the data themselves. Then, following this, axial coding is the process of relating categories to their subcategories and testing against the data. Finally, selective coding is a means of unifying relevant categories into a “core” category that represents the central phenomenon of the study.

Open coding entails a constant process of questioning and comparing that serves to limit researcher subjectivity. Open coding stimulates generative and comparative questions to guide the researcher in future coding and interpretation and in theory development, and may even guide the researcher to return to the field for more data. Open coding is in a sense the initial structured conversation between the researcher/theorist and the data. It has been described as like the first peek at the insides of an egg freshly cracked and poured into a pan.

### Application

Open coding, in contrast to axial and selective coding, is not directed solely toward the whittling down of data into a manageable mix of concepts, perceptions, patterns, and actions. Rather than reducing information, open coding begins to organize it into meaningful categories. In some senses it could be described as a process of critical translation by which the researcher, on a word-by-word basis, identifies and organizes raw data into broad categories of words, actions, and perceptions.

In open coding, the most mundane categorical identification is completed. For example, open coding ensures research subjects are clearly identified, and demographic and other relevant personal and professional information, such as gender and age, occupation, professional relationships, and responsibilities of the participants, is applied. However, this is not to say that open coding takes place only at such a mundane level, since it progresses from this very matter-of-fact level of analysis to entail meaningful theoretical and intuitive sensitivity to multiple perspectives and issues of gender, sexuality, class, and race and other differences and relationships between and among the study sample.

Open coding is the commencement of a long process of working the raw data, through constant comparison, initial conceptual identification, and categorization. As the first and perhaps most important reading of the data, during open coding the researcher is especially interested in identifying and illuminating patterns and concepts but not refining or delineating, which is completed during later stages of the data interpretation process.

Open coding could perhaps best be described as an intense interplay, or perhaps more accurately as an intense and somewhat repetitive argumentative conversation between two people who have been introduced but are not overly familiar with each other, and are focused on constantly comparing their own interpretations of their experiences for the purpose of guiding future, more detailed conversations.

### Critical Summary

Open coding is the initial conversation between researchers and the voices, actions, and events of their raw collected data. It requires a high degree of researcher intuition and theoretical sensitivity. It is by nature a rigorous and painstaking process of analyzing or translating, word for word, raw data into usable theoretical or conceptual chunks or categories. It calls for constant comparison, theoretical questioning, and questioning of data. It is, in short, an intensive process by which data are rigorously analyzed for embedded phenomena, patterns, concepts, and themes. Open coding is often enhanced by data collection from multiple but comparable cases or samples.

## CODING: SELECTIVE CODING

---

*Selective coding* refers to the final stage of data analysis to be completed after core concepts emerging from the coded data categories and subcategories have been identified through open and/or axial coding. During selective coding, previously identified discrete concepts and categories are further defined, developed, and refined and then brought together to tell a larger story. Selective coding is the stage in data analysis where core concepts are identified, and then abstracted, yet empirically grounded theory is generated.

### Conceptual Overview and Discussion

Selective coding, which is also referred to as substantive coding, takes place after initial core categories and concepts have been identified in the data. Selective coding concentrates on theoretical development regarding the nature and relationships of core or essential categories and concepts emerging from the data being worked. The results of selective coding can range broadly from grounded explanations of behavior drawn from core categories, to the creation of broad theoretical abstractions based on these core categories, which serve as the building blocks for grounded theory. Selective coding, although often thought of as the final stage in data coding, can often lead the conscientious researcher back into the raw data for a final search for data related to the core codes developed during open and axial coding stages. While the effect of open and axial coding is the systematic fragmentation of the data into core codes and concepts, selective coding is a heuristic process of reconstruction and reconstitution. It is not uncommon to categories and subcategories.

Although any discussion of the methodology of grounded theory must involve a discussion of the pathbreaking work of Barney Glaser and Anselm Strauss, it is important to note that substantive differences developed over time between these two pioneering sociologists, not least of which was their individual understanding of selective coding. For Strauss, selective coding is a crucial stage in theoretical development that calls for highly developed theoretical sensitivity on the part of the researcher. The process of discovering and abstracting and articulating theory from data that has been coded in a systematic fashion through open and axial coding into a number of categories and subcategories requires significant intellectual finesse and an eye for nuance. In contrast, Glaser constructs selective coding as an almost automatic result of the previous stages of data analysis where relationships between data have been repeatedly compared and contrasted. For Glaser, the coded data are in a sense self-selected through the evolving process of data analysis, and the selective coding stage is essentially about clearly identifying, exploring, and clearly articulating core concepts in theoretical terms. Glaser was concerned that Strauss's almost scripted approach to the methodology of coding might lead to researchers making data fit categories, and therefore, data and categories that fit theory, rather than finding categories and theories that emerge from data.

### Application

In case study research, selective coding is the culmination of an intense process of discovery and exploration of an institution, event, or individual. As the initiating stage for theoretical development, selective coding is in essence about articulating empirically grounded theoretical statements that are designed to explain or understand social behavior or social problems.

Kui-Hee Song explored the issue of resolving child abuse problems in Korean immigrant populations through a grounded theory case study of an American Korean immigrant family. This family was working to resolve abuse through clinical intervention by child protective services. In this highly detailed case study the author attempts, through grounded theory, to explore the possibility of applying theoretical ideas related to postmodernism

and multiculturalism. Song was interested in understanding the therapeutic process and cross-cultural communication involved in resolving child abuse concerns across cultural differences. In order to deal with the inherent difficulties in coding and interpreting data across language, Song developed codes incorporating Korean conceptual understandings. To aid in the reliability of her codes, Song employed another researcher to code much of her data independently.

Open coding began with transcripts of interviews with the family at the focus of the case study. Some preliminary possible codes or categories were identified in advance of the interviews by the researcher as she was utilizing a number of data sources in addition to participant interviews, including documentary report analysis, respondent letter, and participant observation notes. However, the core categories regarding the clinical resolution process emerged from taped transcripts of interviews. Transcripts were read and reread by Song to refine and define the core categories of her research, a process normally defined as axial coding. Song then engaged in the theoretical generation or *selective coding* of her data, where she selected her core categories, explored the inter- and intra-relationships of the categories, and began to generate hypotheses and theories to bring insight into the complex process of cultural communication and negotiation in cross-cultural institutionalized settings.

### Critical Summary

Selective coding is an integral process in grounded theory data analysis and theory development. It is a deductive and creative process. It is the point in the data analysis process where the researcher begins to apply theory to the core categories of the collected and open-coded data, and to generate theory from the data. It demands both intellectual rigor and theoretical sensitivity. Selective coding begins after the identification of core categories. It is a process of both discovery and illumination, which can result in theoretical generation of different levels of abstraction from the data, while still being empirically grounded in the data.

## COGNITIVE BIASES

---

*Cognitive bias* is a general term used to describe a tendency to make a systematic error in thinking or reasoning. Normative systems such as formal logic, probability theory, and choice behavior by formal decision theory have been used by psychologists and economists to evaluate and detect cognitive biases in human reasoning. Unless actively avoided, cognitive biases can influence the manner in which human beings think about planning, executing, and interpreting data collected for research studies, including case study research.

### Conceptual Overview and Discussion

Cognitive biases often occur when people use shortcuts in thinking. In the 1960s, Amos Tversky and Daniel Kahneman began their pioneering research on biases when they discovered that experts were overconfident in the replicability of results from small samples. These shortcuts in thinking, also termed *heuristics*, work reasonably well when people need to make quick decisions. However, heuristics can lead to systematic biases in thinking, especially in situations calling for systematic and logical reasoning.

Leda Cosmides, Gerd Gigerenzer, and Steven Pinker theorize that the ability of human beings to make quick decisions has evolutionary value because in some situations, especially those deemed dangerous and harmful to our survival, quick responses are vital. Furthermore, cognitive scientists such as Jonathan Evans and Steven Sloman

hypothesize that the ability to make quick decisions is part of the brain's dual information-processing system. One part of the system is conscious, slow, and sequential, linked to working memory and measured intelligence, capable of abstract and hypothetical thinking, able to be controlled, and effortful; the other part is unconscious, rapid, associative, pragmatic, efficient in memory resources, independent of general measured intelligence, and relatively effortless. Heuristics arise from this second system and often lead to satisfactory outcomes in vital situations; however, they can also lead to serious errors in thinking that should be avoided in situations that call for more controlled and effortful thought.

Cognitive biases can arise in almost all forms of thinking and reasoning, including quantitative judgment, decision analysis, moral thinking, and social dilemmas. While many examples of cognitive biases exist in the psychological and economic literature, common cognitive biases expected to arise in case study research include those pertaining to hypothesis testing, judgments of probability, and correlation and contingency. Classic examples of cognitive biases in judgments of probability include the hindsight bias and biases arising from the representativeness heuristic and the availability heuristic. In hypothesis testing, commonly illustrated examples of cognitive biases include the congruence or confirmation bias and the information bias. Finally, in judgments of correlation and contingency, pertinent cognitive biases include the attentional bias, and those arising from the effects of prior belief leading to illusory correlations. A brief definition for each of these biases follows.

*Representativeness Heuristic.* Estimating the probability that an event A belongs to (or originates from) a particular class B by evaluating the degree to which A is similar to or typical of B. This heuristic can lead to errors of judgment because it ignores prior probabilities of classes (i.e., the prior probability or base rate of B) and therefore can lead people to categorize events incorrectly into classes.

*Availability Heuristic.* Estimating the probability of event A versus event B by the frequency with which A and B can be brought into memory. This heuristic can lead to errors of judgment because a

memory search for instances of A and B may be governed by what people find salient about A and B and not by a proper sampling of A and B.

*Hindsight Bias.* The tendency for people who know a particular event A has occurred to overestimate the probability with which they would have predicted its occurrence before it took place.

*Congruence or Confirmation Bias.* The tendency for people to confirm their hypotheses or expectations through direct tests (e.g., if you expect event A to be found behind door No. 1 and not door No. 2, checking door No. 1 exclusively) instead of falsifying their hypotheses through indirect tests (e.g., if you expect event A to be found behind door No. 1 and not door No. 2, checking *both* doors No. 1 and No. 2).

*Information Bias.* When deciding among different courses of action, the tendency for people to seek out information for purposes of curiosity that is devoid of value for deciding a course of action.

*Attentional Bias.* The tendency for people to ignore evidence or avoid looking for evidence against an initial hypothesis, in addition to a failure to consider alternative hypotheses.

*Effects of Prior Belief (Illusory Correlation).* Persistent beliefs or expectations about what variables ought to be associated can lead to the perception of a systematic correlation between those variables even when none is present; persistent beliefs can also lead to a failure to detect correlations that are actually present.

## Application

The cognitive biases defined in the previous section can contaminate all forms of research, including case study research. In case study research, an iterative analysis of cases is often undertaken to identify emergent themes (and explanations) to answer a research question. Repeatedly reviewing cases to find common themes and explanations for events lends itself to potentially eliciting cognitive biases. For example, in the process of classifying

case events or occurrences into categories, researchers could unknowingly invoke the representativeness heuristic by neglecting to consider the prior probabilities of the categories being considered. Likewise, the availability heuristic could be invoked by using categories that have been used in past research but that do not apply well to the case events under consideration. The hindsight bias could also contaminate thinking by distorting the perceived likelihood of events in case studies. Cross-checking data analyses by having multiple cases and methods of classifying or sorting data by several investigators can help improve reliability and validity arguments.

Case study research also lends itself to committing the congruence or confirmation bias and the information bias. Because case study research often involves selecting key cases to observe and study, investigators need to avoid selecting only those cases that will confirm their hypotheses and ignoring cases that stand to falsify their hypotheses. Although some cases may appear understandable to include for analysis because of their match or relevance to the research question posed, too much focus on a direct test of a hypothesis may obscure inclusion of indirect tests; that is, including cases that appear to negate the hypothesis being considered. Finally, the information bias can be avoided by continuously recognizing the objective of the analysis and avoiding the temptation to include and/or review cases or case events simply out of curiosity.

The final two biases—attentional bias and illusory correlation—share similarities with the others described previously. Attentional bias can contaminate case study research when a single hypothesis is considered and alternative hypotheses are not. Attentional bias can feed into a confirmation bias when the researcher seeks to confirm a single hypothesis by attending to a narrow set of cases or events (data) that essentially provides positive evidence for the hypothesis under consideration. The final bias can result from the effects of prior beliefs. Although prior beliefs inform the generation of research questions and hypotheses and are therefore needed in conducting scholarly investigations, they have also been shown to influence the interpretation of data. For example, prior beliefs can lead investigators to believe that a relationship exists between

two variables where none actually exists—a bias labeled illusory correlation.

### Critical Summary

Cognitive biases, reflecting systematic errors in thinking or reasoning, arise from the quick, pragmatic, and adaptive nature of one part of our information-processing system. Although cognitive biases may be highly useful in helping us make quick decisions in hazardous environmental conditions, they can lead us astray when making decisions in situations that require controlled, thoughtful, and logical thinking such as in scientific endeavors. There are a variety of cognitive biases that have been identified in the literature, and seven were defined and illustrated here. Investigators conducting case study research can avoid committing these seven cognitive biases by generating empirically grounded rationales for the categories used to evaluate and classify cases, and recognizing the need to seek falsifying evidence for “pet” hypotheses.

## COGNITIVE MAPPING

---

One way we provide meaning to our world is through the development of mental representations. It is through our ability to code, store, recall, and decode information about the locations and attributes of objects in our world that we are able to discriminate and classify phenomena. By developing cognitive maps, it is possible to maintain and retrieve visuals, space, and movement; to manage phenomena; and to illustrate relationships and connections between these entities. Mapping these mental representations allows the brain to guide behaviors and thought processes. How this is achieved is discussed by cognitive researchers, and the application of cognitive maps is evident in the qualitative research and educational environments.

### Conceptual Overview and Discussion

The origin of cognitive mapping is derived from the field of cognition examining the internal mental models constructed by individuals. First introduced in 1945 by John von Neumann, cognitive mapping was used to compare computers and the human brain. The electronic circuits of a computer were described as analogous to a neuron firing in the brain, while computer programs were a metaphor for the way in which information was detected, stored, and recalled by the brain. This comparison was used by Edward Tolman to explain how mice repeatedly navigated their way through mazes. By developing a “map” of sensory information using smell and movement, mice were able to use selective recall to navigate through mazes. These behaviors were fine-tuned over repeated iterations.

During the 1980s, contemporary cognitive psychologists revisited this behavioral approach, arguing that human behavior is purposeful and goal-directed with intended expectancies to meet directed activities. Albert Bandura, for example, proposed that humans used activities to guide themselves and others through the behavioral, cognitive, and social processes of daily life. He illustrated this by arguing that a role of parents is to guide their children over time by articulating information to create boundaries that children can use

to organize and interpret their world. The success or failure of this cognitive mapping is judged by the outcome of a child’s behavior. The parents observe, reward, and/or generate new feedback depending on this outcome.

Cognitive mapping is well suited as a tool in qualitative research studies. It is particularly useful in case study research as it focuses on purposeful behavior in response to a phenomenon. To explore how individuals relate and respond to a given phenomenon, a “map” is created based upon assumptions, guidelines, and practices. By establishing boundaries through a series of geographic, temporal, organizational, institutional, or other defining criteria, a “map” is created that explains how a given phenomenon is realized in a specific context. Research studies are based on the design of structures that gather and analyze information by identifying, observing, and articulating the phenomenon in question. Developing cognitive mapping procedures enables researchers to see the phenomenon and to propose a conceivable research framework that can then produce problem-solving opportunities.

### Application

Cognitive mapping is used by David Ausubel in the development of advanced organizers. He uses this method as a tool to provide a cognitive instructional strategy that promotes learning and retention of new information by students. By displaying phrases of words, students are exposed to a way of thinking about a subject prior to investigating it in detail. Richard Mayer notes this classification system enables learners to cognitively map or organize new information onto existing mental frameworks of categories or schemata. Existing knowledge is housed in expository organizers, while schemata that build connections between existing knowledge and new information are known as comparative organizers. Together, these cognitive maps enable the learner to accept, store, retrieve, and utilize existing with new information, to transfer knowledge, and to follow the process of problem-solving behavior and strategies.

Ausubel indicates this process is frequently used in schools for note-taking, learning new vocabulary, motivating students to read, and learning at higher levels of abstraction, generality, and inclusiveness. In each case, the development of cognitive

maps through advance organizers provides methods that can assist students to learn, to retrieve information previously presented and at the same time, teach and add new concepts. Organizers are therefore cognitive maps designed to conduct and evaluate learning while providing meaningful learning for students.

Reuven Feuerstein applies the concept of cognitive mapping in a different way by exploring the mediated learning experience between parent and child. The parent selects; organizes facts, words, or instructions; and then frames, filters, and organizes these for the child. The youngster analyzes and categorizes this information with a cognitive map composed of at least seven parameters including content, operations, modality (i.e., figurative, numerical, or verbal), phrase, (i.e., input, elaboration, output), complexity, abstraction, and efficiency. The aim is to establish this new information into a cognitive map or a framework that the child has developed, understands, and can utilize. Young children are very quick to process information once they have developed early personal maps to incorporate new information. In fact, parents are often surprised at the speed at which young children can use these internal maps in unexpected or surprising situations.

Building on the work identified by others, Clive Lawless describes a distinctive feature of cognitive mapping within the education field. He notes that mapping is commonly used to emphasize relationships between entities, offering ways to describe and visualize concepts. In this case, the psychological process of cognitive mapping is displayed by the use of concept maps. These physical maps represent a structured process, focusing on a topic or construct of interest involving one or more phenomena that enable participants to visually present concepts and ideas.

Learning is thus represented as the accommodation and assimilation of new ideas incorporated into existing cognitive structures. By drawing nodes to represent concepts and lines to indicate relationships, these hierarchical, spider, and other forms of maps can be visually represented. These diagrams are idiosyncratic, offering visual schemata of meaning that vary with knowledge acquisition, time, and situation. A primary advantage of this visual representation is that viewers are able to “see” the relationships and conceptual approaches more clearly.

The applicability of these diagrams can be particularly useful for students learning about a discipline. For example, Josephine D. Wallace and Joel J. Mintzes studied how science methods were learned by student teachers. The cognitive processing steps used in science were displayed by subjects who presented their understanding using a concept map. Compared to a control group, the teachers showed significant development in their understanding of concepts and propositions, and showed an increased amount of knowledge retained and the way in which this knowledge was organized by these teachers. Joseph Novak and Bob Gowin note that concept maps are conjecture and are visual tools that are limited to reflecting a means rather than initiating the “act” of learning.

Other visual representations are discussed in the literature. Mind maps described by Tony Buzan are diagrams representing words, ideas, tasks, or other items linked to a central or key concept. These may be helpful to generalize, visualize, or structure information or as an aid in the study, organization, problem solving, decision making, or writing related to research work. Novak and Gowin offer many practical applications of concept mapping as an extension to the cognitive mapping process.

### Critical Summary

Cognitive mapping is difficult to distinguish today because it is an internal cognitive process. It is much easier to demonstrate the cognitive process through the myriad supporting devices, including concept maps, mind maps, spiderwebs, concept sorting, fuzzy cognitive mapping, semantic maps, networking, idea maps, or word webbing maps. The value of cognitive processing is the ability to represent the schematic that organizes concepts, knowledge, and the relationships between phenomena. The value of this tool is that it reduces cognitive overload, promotes internal cognitive streamlining, and provides enhanced recall and learning of information. All can be very helpful in research and educational settings. The challenge of cognitive mapping is that it is an internal, hidden process that is difficult to prove without the presence of visual representations.

## COLLECTIVE CASE STUDY

---

Collective case study involves more than one case, which may or may not be physically colocated with other cases. A collective case study may be conducted at one site (e.g., a school, hospital, or university) by examining a number of different departments or other units at that one site. Each unit is studied as part of a collection, regardless of whether the units themselves are located at single or multiple sites. The term *collective case study* is sometimes referred to as *multi-site case study* or *multi-site study*. There seems to be little difference in the definition of these terms. Although 21st-century scholars may struggle to find an appropriate label for this type of research, the method itself is not new.

### Context

Collective case studies first emerged in the 1960s and 1970s as a way to gather qualitative data that went beyond a single case study. Prior to this time, single case studies were often conducted by university researchers. Collective case studies were often done as part of larger projects, funded by governments or

policy research institutes. They typically focused on quantitative research, were at least 2 years in duration, and were expensive to conduct.

While large-scale policy research may be a modern use of collective case study, the method itself appears to have historical roots in 19th-century European sociological research. One documented case of what we would call collective case study was conducted by Frédéric LePlay (1806–1882), a French sociologist who studied cases of working-class families to better understand how each family unit functioned on its own, and from there drew conclusions about how families function within society. LePlay's study was called a *monograph of families*. Although the term *monograph* is rarely used to talk about case studies today, the research methods are essentially the same.

Regardless of the name, the common theme among collective case studies is that they examine the same research question(s) within a number of contexts, using identical methods of data collection and analysis. The researcher wants to understand the individual site and develop a comparison of all the sites. The individual units of study, then, or cases, are examined in situ and can be considered as a collective whole for the analysis phase.

### Conceptual Overview and Discussion

This research design is used to undertake a close study of a number of cases that are linked together, either through a common issue or other similarities. The important point is that the cases must share some link or there is no point in them being studied as a collective.

In a collective case study, a common set of research questions is developed to guide the study of each individual case. Each case is treated as its own individual entity, and researchers take an in-depth approach to each one. A collective case study approach is especially useful in social settings such as schools, where the distinctions between the context and the events being observed are sometimes blurred.

It is important to note that case studies are conceptualized within the qualitative paradigm but may include both quantitative and qualitative data. The context in which the research is conducted is considered important and is usually discussed in the results of the research. Robert Yin

notes that what makes case study different from a quantitative or experimental study is that in case study the phenomenon under study is examined within the context, and not artificially taken outside of the context in which it exists and observed as though it were devoid of context.

One purpose of the large-scale policy projects of the 1960s and 1970s was that they provided the opportunity to integrate quantitative and qualitative data, and allowed for cross-case comparisons. This can make the overall research project quite extensive in scope, and a potentially expensive endeavor.

The notion of cross-case comparisons is important for collective case study because what differentiates this from traditional single case study is that the researcher is interested in, and preoccupied by, commonalities among the cases. The cases are linked and bound by their common characteristics, which are what the researcher is most interested in exploring and understanding. Robert Stake refers to this grouping as a *quintain*. The term *quintain* offers a concise way to refer to the data that are most pertinent to this type of research. Rather than focusing on single events or contexts, in collective case study the researcher is seeking a better understanding of the *quintain* or collection of categorically bounded cases.

It is worth underscoring that even though the *quintain* or collection is the main focus of the research, each case is still studied in an in-depth manner. The careful and thorough examination of each individual case within the *quintain* is essential, and the desire and need to understand each individual case deeply is not sacrificed for the sake of gathering surface data quickly. This means that a collective case study requires a thorough and methodical approach, not to mention significant resources in terms of the researcher's time and funding. This brings us to some of the limitations of this type of work.

### Limitations

Collective case studies, by definition, examine at least three distinct cases. Though there is no limit to the number of cases that could potentially be studied, the scope of the study is often limited by both the timeline of the project and the budget. Although a collection may include all possible

cases, it is more likely that it will include a selection of cases.

Though some argue that because case studies are bounded by time and space, and the very nature of case study involves researching in a current context, it is more likely that budget, rather than space, would limit a collective case study. Cases could be investigated in a variety of locales, provided properly trained researchers could be found. Securing funding for large-scale collective case research in a global context could be a significant challenge or limitation.

In addition to budgeting financial resources, a collective case study must also budget its time carefully. The length of time spent at any given site should be more or less equal to the amount of time spent at other sites. If significantly more time is spent at one site, it may limit the amount of time available to study other sites, which creates the potential to compromise the quality of the data collected.

Due to the scope of the research, it is not always possible for one person alone to collect all the data required for the study. Different researchers may be required at different sites, supervised by one principal investigator. In order to ensure validity, it is essential that all researchers are briefed and trained in similar ways. This helps to ensure as much control as possible not only of the data collected but also of the ways in which they are collected, a process that helps ensure validity for comparative purposes. These are important limitations to acknowledge in a collective case study project. The richness of the data collected and the potential for deeply understanding a phenomenon in its context are the benefits of the results of research that involves complex methodology.

### Application

To conduct a collective case study, the researcher must first identify the research question(s) to be explored. Consideration of those questions then provides an appreciation of the type of research methodology required. If it is apparent that the study poses questions that may be studied effectively in more than three subsets of a common environment, then the next phase of the research requires the identification of the *quintain*.

For example, a researcher exploring the ways in which teachers hinder or facilitate the academic

success of minority culture children may be conducted in several classrooms (the sites) that are categorically bound together (the school). To conduct the study in such a large number of sites requires a team of researchers, each of whom must be trained to ask the same major and probing research questions, observe and record the same observations in the same way, administer the same survey questionnaires, and collect the same examples of written policy documentation.

Cross-site comparison occurs by the research team taking these individual data sets and combining them for quintain analysis. The data are integrated and analyzed as a whole rather than as separate sets. The results are presented as a collective case study.

### Critical Summary

Collective case studies examine at least three cases in any given study. Though some studies involve dozens of cases, the scope of the study is often dictated both by the type of data desired and the timeline and budget for the project. Collective case studies are typically long-term projects of at least a year and may often be expensive to conduct, due to the number of cases involved and the number of researchers who must be trained. Such studies deal with present-day issues and data, and use living subjects to collect data, often through observation, interviews, questionnaires, or other methods. They may collect qualitative or quantitative evidence, or a combination of these. The main reason for conducting a collective case study is to explore cross-case comparisons and draw generalizations from the entire collection to understand the phenomenon deeply from a variety of perspectives.

## COLONIALISM

---

Colonialism is an influential interdisciplinary concept with a long history. It has figured prominently as an analytical framework in the extensive literature in many fields of study, including history, sociology, anthropology, political science, and international relations. The term *colonialism* derives from the Greek word for colony. Originally, a colony referred to the permanent settlement of a place by a group of people who migrated there from their homeland. During the late 19th century, the word began to be used to refer to all distant territories subject to the direct rule of a foreign, usually European, state. It is this meaning that is most commonly used today. Colonialism is the political rule or control of peoples and territories by other states, whether or not this is accompanied by permanent settlement. When there is significant permanent settlement, such colonies are referred to as settler colonies.

### Conceptual Overview and Discussion

Colonial rule is usually long distance; it involves the imposition of political control by one country over another separate territory. Colonialism is closely related to the word *imperialism*, which describes the domination by one people or state (or a group of them) over others in a manner advantageous to the former and usually at the expense of the latter. But the two are to be distinguished. Colonialism is only one form imperialism might

take. Imperialism can take various forms of indirect control or domination without colonies. The concept of imperialism also implies international politics where great powers exert control over weaker states and/or manipulate colonies as part of international power struggles.

Empire-building through colonial expansion has a long history, dating back to ancient times; an example is the Roman Empire. Before the 16th century, the main type of empire was a land-based empire that grew through the acquisition of territories by expansion over land. This kind of empire was created by various people in different parts of the world. Seaborne colonial empires, by contrast, are more recent. They emerged in the 16th century and lasted until the mid-20th century. They are created through the acquisition of colonies overseas, and they span the oceans.

Most of the overseas empires of the past 500 years were European. A number of writers argue that European colonialism was different from the creation of empires in earlier times in terms of motives, main agents, and outcomes. It was connected to the rise of capitalism, which originated in Europe. Some scholars also distinguish different stages of European colonialism and relate these stages to the development of capitalism. The main distinction made is between the last great wave of colonial expansion in the late 19th century and the colonialism of the previous two centuries.

The colonialism of the late 19th century was the child of industrial capitalism and intensified competition between rival industrialized capitalist states. It differed from its precursors in significant ways, including the type and volume of overseas investment, new markets for industrial goods, the kinds of raw materials and infrastructure demanded by industrializing European economies, and the increased intervention of states in their national economies and its impact on the form of colonial rule. The relationship between colonialism and capitalism has been the subject of voluminous research. Some scholars dispute the distinctiveness of the colonialism of the late 19th century, arguing that it was not qualitatively different from the colonialism of previous eras.

The period from the end of the Second World War to the late 1960s saw the rapid decolonization of the overseas European empires. Many colonized territories in Asia and Africa gained their political

independence. However, they were left with the legacies of colonialism that made it very difficult to create stable political systems and self-sustaining economies. Colonialism was not only political and economic but also cultural. It was supported by, and propagated, ideologies of the racial and cultural superiority of the colonizer. Colonialism transformed ideas, images, and representations in both colonized and colonizing societies, although the extent and significance of this transformation has been disputed.

### Application

Research of the European colonies flourished in the late 19th and early 20th centuries. Much of this research was commissioned by the colonial administrations. The objective was to assist colonial policy. Academics also conducted various studies of colonial societies. Case study was one of the major research methods used. An interesting example is the University of London anthropologist Phyllis M. Kaberry's *Women of the Grassfields: A Study of the Economic Position of Women in Bamenda, British Cameroons*. This 1952 study appeared in the British Colonial Office's Colonial Research Publication series.

Scholarly interest in colonialism waned in the period from the 1950s to the 1970s as many former colonies became independent. In the first stage following decolonization, the focus of intellectual attention shifted to the modernization of the new states. Colonialism was no longer an attractive subject. In the second stage, scholars started to pay more attention to the persistent economic and technological dependence of the former colonies on Western industrialized countries despite their political independence. Thus neocolonialism and dependency became a flourishing field of study during the 1960s and 1970s. The underlying question concerned the inability of the former colonies to achieve development and gain their economic independence. According to studies of neocolonial relations and dependency situations, the roots of underdevelopment in Latin America, Africa, and Asia are found in the earlier European colonial domination and exploitation of these regions.

Extensive research has been done on the economic effects of European colonialism for the colonized, and some is based on the case study method. One such case study is Rhoda Howard's

*Colonialism and Underdevelopment in Ghana*, published in 1978. Many studies show that colonial rule transformed local economies into sources of cheap raw materials and labor to feed European industries. In cases where precolonial economies were ripe for an industrial take-off, as in India, the colonial system destroyed local industries. The result was the *underdevelopment* of colonized countries. The colonized countries may have been undeveloped before their colonization, but they became underdeveloped as a result of their colonial exploitation. Not all scholars agree with these negative assessments; they instead highlight the positive economic contributions of colonial rule. They point out that the colonized countries owed their modern infrastructure to colonial administrations. Colonial rule encouraged urbanization and put in place modern education and legal systems.

The term *neocolonialism* first came into use in the 1950s to describe the continuation of the colonial domination of former colonies without direct political rule. The Third All-African People's Conference of 1961 produced an influential list of neocolonial features, including the following: installation of client regimes; inheritance of the same administrative units created by the former colonial powers; economic and financial dependence after political independence; and the use of economic aid and military grants as a substitute for direct colonial rule. Neocolonialism is also used to describe the influence of transnational corporations and international financial institutions in the politics and economics of the less developed countries. In his 1975 book *Underdevelopment in Kenya: The Political Economy of Neo-Colonialism*, Colin Leys offers a comprehensive case study of the mechanisms of neocolonial domination in postindependence Kenya.

The term *neocolonialism* was mostly abandoned in the 1980s, partly because of its polemical use in Cold War politics. However, it can still provide us with a useful explanatory framework for those cases where a foreign power exercises significant control over a less powerful state in a manner that is functionally similar to the system of colonialism but without formal colonial administration.

A group of Marxist-influenced scholars formulated dependency theory during the 1960s and 1970s, the object of which was to explain the underdevelopment of the global South and the gap

between rich and poor countries. Dependency theory encompasses the notion of neocolonialism, but it emphasizes the structure of the world capitalist economy, which is characterized by a divide between the periphery and the core. The founding dependency theorists include Fernando Henrique Cardoso, Enzo Faletto, and André Gunder Frank. Their main concern was to understand why Latin America remained underdeveloped vis-à-vis the advanced capitalist countries despite its political decolonization long time ago. Dependency theory was later applied to Asia and Africa as well. Some dependency analysts conducted case studies of underdeveloped countries or regions. A seminal case study of Africa from the perspective of dependency theory is Walter Rodney's *How Europe Underdeveloped Africa*, published in 1972.

Dependency theory argues that the underdevelopment of periphery countries is due to their involvement with the capitalist countries in the core. Dependency is described by asymmetrical links between countries. But it is not merely a relationship of dependence between countries. It connotes the extent to which the economic and political dynamics in the periphery are conditioned by the world capitalist economy dominated by the core countries. Dependency often involves collaboration of the periphery elites with the ruling elites and transnational corporations of the core. Such collaboration might benefit the elites in the periphery; but it also reinforces the periphery's dependency. Dependency theory was subjected to a barrage of criticism. It was accused of attaching too much importance to international factors and not enough attention to domestic structures in underdeveloped countries. It was also criticized for focusing too much on capitalism and not enough on unequal power among states in explaining dependency. It could not explain the successful development of several East Asian countries in recent decades. Nonetheless, the questions raised by dependency theory remain relevant for many postcolonial states.

Postcolonialism emerged as an influential perspective in the humanities and social sciences over the past couple of decades. The prefix *post* indicates postcolonialism's reliance on postpositivist approaches to knowledge rather than the end of colonial practices. Postcolonial scholars look at how discursive constructions shape our understandings of the world. Their starting point is the

global hierarchies of control. Most postcolonial studies focus on the persistence of colonial forms of power in the contemporary world. They emphasize the intersectionality of race, gender, class, and colonial power. The key thesis is that colonial forms of domination rely on the social production of racial, gender, and class differences. While examining the continuity of colonial forms of power, postcolonial scholars are also interested in diverse forms of resistance by subaltern peoples to colonial domination.

### Critical Summary

Many decades after the end of colonial empires, there is a major revival of scholarly interest in colonialism. This growing stream of research crosses the disciplinary boundaries of anthropology, history, international relations, and literature. The past two decades have seen numerous publications in colonial studies, which examine various aspects of the colonial world. Topics range from indigenous–European settler encounters to the representations of women in colonial literature. This resurgence of scholarship on colonial studies is mainly as a result of the influence of new intellectual approaches that question the earlier, mostly Eurocentric studies of the colonial world. The recent body of research calls into question the narratives that represent the colonized societies as static and backward. However, like postcolonial studies, which are concerned with the legacies of colonialism as well as the different forms of contesting (neo)colonial domination, the recent scholarship on colonial studies mostly takes a cultural perspective and focuses on the cultural aspects of colonial situations. What is usually neglected is colonialism as a system of economic exploitation and political control.

## COMMUNICATIVE ACTION

---

Communicative action, the key to Jürgen Habermas's work, refers to the interaction of at least two people who seek to reach an understanding about something so that they can coordinate their interpretation of a situation and their plans of action by way of mutual agreement. Language is presupposed as the medium through which speakers and hearers, situated in the prior context of their own lifeworld(s), can refer within the communicative relation to the objective, social, and subjective worlds and in the process raise validity claims correlative to these world relations.

### Conceptual Overview and Discussion

The subject–object relation of the philosophy of consciousness (from Descartes through Kant and Hegel to Smith and Marx), according to Habermas, is now exhausted; hence his “linguistic turn” away from individual action to communicative action and a focus on the communicative relation between people as the core building block for philosophical, social theoretical, and empirical analysis.

It is useful initially to distinguish between *The Theory of Communicative Action*, which is Habermas's mature exposition of his critical theory of society and late modernity, and communicative action itself, which is the point of departure for this theory. The two volumes run to more than 1,200 pages and the reader is referred to Thomas

McCarthy's superb translator's introduction to the 1984 edition for probably the clearest synopsis of the sheer breadth and depth of this major 20th-century work.

At a macrolevel, this theory presents a two-level conceptualization of society that (a) integrates both lifeworld and system approaches; (b) maps a philosophical and social theoretical way out of the aporias and limits within the individualistic subject-object relation by providing a groundbreaking conceptualization of communicative rationality (as distinct from individual means-end, instrumental, or strategic conceptions of rationality), that draws on "language-in-use" and speech act theory; and finally, in genuine Frankfurt School tradition, (c) provides a sophisticated means of addressing the pathologies of late modernity in suggesting that the original emancipatory intent of the Enlightenment project is not exhausted but simply unfinished and that this theory identifies the pathways for substantive analysis, explanation, and human intervention to ameliorate or redress such pathologies, thus leading to a more critical redirection of this project.

The first and third points above are briefly addressed here, simply to note the macrolevel of analysis before moving more deeply into discussing the procedural dynamics of communicative action. The financial crisis, as it unfolded during September 2008, may be viewed through the macro lens of the theory of communicative action as it relates to the lifeworld and the steering systems of money and power. In very simple terms, and from a political economy and "critical management studies" perspective, a systemic failure was allowed within the banking system and an alliance quickly formed between the elites of both the money and the power systems on how to save extant economic structures from further collapse. Costs of the various "bailouts" of the money system, facilitated by the governmental agents of the administrative power system, were largely burdened on future citizen taxpayers with consequences for their working and private lives in their own particular lifeworlds. These citizens did not cause the pathology, yet private system losses and risks from the mortgage-based financial system were socialized at the expense of the general public and taxpayers. Many critical research questions may be addressed here by drawing on the entire

theoretical architectonic of the theory of communicative action at both macro- and microlevels of analysis and from both participant and observer methodological perspectives.

Communicative action is central to the healthy functioning of human lifeworlds: Under the functional aspect of reaching understanding, it serves to transmit and renew cultural knowledge; under the aspect of coordinating action, it serves social integration and the establishment of group solidarity; and under the aspect of socialization, it serves the formation of personal identities. At this microlevel of analysis, communicative action is a two-way dynamic process with three clearly identifiable validity claims related to the objective, social, and subjective worlds. When two or more people communicate with each other using face-to-face speech acts, body language, electronically mediated, or other means of communication, each utterance or speech act that *One* makes can be implicitly or explicitly accepted or challenged by *Other* on a simple "Yes" or "No" basis. *One* is seen as making a claim to validity with each utterance, and *Other* can either accept or reject this claim.

Assuming the general claim to comprehensibility, the corresponding validity claims of propositional truth/efficacy related to the objective world, normative rightness related to the social world, and sincerity/authenticity related to the subjective world are available. All speech acts, however implicitly, make these three claims, although one may be emphasized more than the other two in any particular situation. Claims in this instance are not settled by recourse to hierarchical authority or power, which may very often be the case in steering system settings, but by providing reasons for or against in the mutual give-and-take of this rational argumentative discourse. This procedural structure can be shown to be universally valid in a specific or particular sense, thus satisfying social scientific requirements for "objectivity" in a postfoundationalist manner. One must stress that only the procedural aspects of the communicative relation are deemed to be universal; communicative actions are always contextual.

### Application

Communicative action is grounded in language, speech acts, and argumentation; hence it is open to

empirical investigation. It has generated much theoretical debate in the fields of morality, ethics, religion, justice, democracy, globalization, cosmopolitanism, political economy, organization and management theory, communications, politics, and law. Empirical work in some fields is reasonably developed and in others it remains in its infancy, but the range of possible applications in a globalized and more cosmopolitan world is vast.

The problems that caused the September 2008 financial crisis noted above must have emerged, if in part, in the boardrooms of the financial organizations concerned. Within the field of corporate governance there is much that we still do not know about what really goes on within such boardrooms, mainly due to understandable difficulties with gaining entry for research purposes and issues of confidentiality. The external observer, however, has no access to the meanings inherent in the various talk-based actions within such boardrooms; to access meaning one must get into the communicative actions somehow.

In her “talk-based” ethnographic case study of a board of directors and senior management team “in action” in a manufacturing company, Dalvir Samra-Fredericks provides an exemplar of how communicative action can theoretically inform in terms of its interpretive framework, guide a rigorous and systematic methodology, and lead to substantive research findings in a complex and difficult research area. Routine, daylong monthly board meetings were attended for over a year, and field work included observations, interviews, workshadowing, and audio- and video recordings of “naturally occurring events.” Using samples of board dialog from the case study, the validity claims within communicative action are placed at the center of empirical speech-act attention, and provide the tools for a much richer illustration of the skilled nature of the board’s interactive routines and behavioral dynamics to be made more transparent. When one observes “boards-in-action,” what one sees, according to Samra-Fredericks, are managerial elites talking to each other. Whether in boards, or elsewhere, such conversations are the empirical focus of analysis through the lens of communicative action.

Face-to-face communication ranks highest in terms of communication richness. Since the advent of the Internet much communication is now electronically

mediated, and in the developed world, at least, e-mail has now become a taken-for-granted in both systems and lifeworlds. Researchers within the field of information systems were among the first to recognize the potential of, and to apply insights from, the theory of communicative action at both micro- and macrolevels.

Ojelanki K. Ngwenyama and Allen S. Lee’s exploration of communication richness in e-mail is explicitly based on this theory where they address the “how” and “what” of communicative practices in a media-use, as distinct from face-to-face, situation. At the microlevel the validity claims within communicative action, based on intensive exploration of one episode of how managers use e-mail, are again the focus of attention. In the process they demonstrate how the intersubjectivist approach may be drawn on to critique individualist-based information richness theory and through empirical illustration present a more theoretically sophisticated definition of communication richness.

The broad critical intent of the theory of communicative action is also made explicit in that instrumental and strategic actions are differentiated from the more discursive form of communicative action. Where a person recognizes instances of distorted communication, for example, someone being latently strategic or not being genuine or sincere, then emancipation becomes possible. In all cases, identifying the relevant validity claim is the key to further analysis and interpretation.

### Critical Summary

The theory of communicative action is not a metatheory; it is best viewed, according to Habermas himself, as the beginning of a social theory concerned to continuously validate its own critical standards. The future of this theory and its potential remain, by definition, open. From philosophy through information systems, language, critical management studies, organization and management theory, law, morality, discourse ethics, democracy, and political economy, applications of the theory of communicative action have produced substantive findings. The relations and validity claims within the communicative relation, and the constraints under which they stand, are substantive and real social phenomena. They are, therefore, open to further broad empirical

investigations from participant, virtual participant, and observer perspectives in diverse fields.

## COMMUNICATIVE FRAMING ANALYSIS

---

Communicative framing analysis is a procedure that allows researchers to study the framing patterns of multiple stakeholders across different research sites. Following particularly Erving Goffman's work, communicative framing refers to the ways in which stakeholders define what is going on in a given situation by foregrounding specific aspects during their interactions. The procedure was first developed to examine framing within and across a series of intractable environmental conflicts. It allows both a fine-grained analysis of different kinds of framing within a

particular case as well as the investigation of dominant framing patterns across several cases.

### Conceptual Overview and Discussion

There are several reasons for using communicative framing analysis. First, it is a mixed methods approach that enables researchers to build a more holistic picture of the phenomenon under investigation. Employing mixed methods ensures that the results are not methodological artifacts and allows researchers to compensate for the weaknesses of one method with the strengths of another. Second, it is especially useful when comparatively little research has been conducted on the phenomenon of study. Third, following Allen Lee's notion of multilevel interpretations, it provides a means for developing first-, second-, and third-level interpretations of stakeholders' framing patterns within and across different cases, and thus enables comparative case analysis.

The procedure starts with the conduct of qualitative interviews designed to capture first-level interpretations of the phenomenon under study by the research participants themselves. Next, Barney Glaser and Anselm Strauss's “constant comparative method” of grounded data analysis is employed to develop a set of framing categories that apply within and across the different cases. Standardized frequency counts of these framing categories are then computed for each of the stakeholders based on a quantitative content analysis of their interviews. These counts are subsequently used to conduct a cluster analysis. This analysis enables a third-level interpretation of the ways stakeholders group together across the cases based on their framing similarities. Using this quantitative method increases the study's reliability and validity. Finally, the constant comparative analysis of the interviews is used again to gain more insight into the ways stakeholders in each cluster frame the phenomenon that is investigated. Examining stakeholders' first-level interpretations within each cluster generates a more holistic understanding of the phenomenon and lends credence and depth to the study, while at the same time improving the “transferability” of the outcomes to other, similar contexts.

### Application

A study by Boris Brummans, Linda Putnam, Barbara Gray, Ralph Hanke, Roy Lewicki, and

Carolyn Wiethoff provides an example of the use of communicative framing analysis. The authors used this procedure to examine how disputants from different stakeholder groups (e.g., farmers, businesspeople, and activists) involved in one of four different intractable environmental conflicts clustered together because they foregrounded similar aspects in their definitions of their conflict situations. The study details the various steps involved in this kind of analysis, entailing the purposive sampling of research participants from the different cases and their classification into stakeholder groups (e.g., farmers, businesspeople, activists); the conduct of semistructured interviews to elicit stakeholders' accounts; the collection of relevant archival data to gain more in-depth insights into the cases; the transcription of the interviews and their open and axial coding to generate "framing categories" that surface regularly in participants' accounts and reveal the specific aspects highlighted by the research participants in their definitions of the situations (e.g., their own identity, the identity of others, power issues); the checking of these inductively derived categories against extant research literature; the conduct of a formal (quantitative) content analysis of the transcripts based on these framing categories; the use of this analysis's outcomes for the conduct of a cluster analysis to determine how research participants from different stakeholder groups form "natural" clusters across the cases based on their framing similarities as well as to determine the dominant framing patterns within each of the clusters; and, finally, the explication of these dominant patterns based on a re-analysis of the interview transcripts.

As Brummans and colleagues' study shows, communicative framing analysis is particularly useful for researchers who want to understand complex, multi-site phenomena that involve various groups of people who view, experience, and enact the world by highlighting different aspects. In so doing, it offers a sophisticated procedure for examining how different groups of people make sense of large-scale phenomena, such as environmental, national, or international conflicts.

### Critical Summary

By combining multiple methods, communicative framing analysis provides a robust procedure for

studying intricate communicative processes across various groups and research sites. In so doing, it allows insight into the ways people make sense of what is going on in a particular situation and helps explain what joins them together as well as sets them apart. The challenges of this procedure lie especially in finding elegant ways to generate synergy between multiple methods of data collection and analysis, and in the management and interpretation of large volumes of different kinds of data.

## COMMUNITY OF PRACTICE

---

How humans acquire knowledge and skills is a central preoccupation for many sociologists and anthropologists concerned with social learning. The term *community of practice* refers to the social context and broader process of social learning and the shared sociocultural practices that characterize specific forms of learning and knowledge acquisition within social groups. The term originated from the work of a few cognitive anthropologists who were engaged with understanding the process of learning through apprenticeship. Jean Lave and

Etienne Wenger are perhaps two of the most notable theorists in this regard, and they coined the term *community of practice* through the development of their ideas about legitimate peripheral participation. Lave and Wenger focused on five forms of apprenticeship (including midwives, meat cutters, tailors, naval quartermasters, and how people become members of an Alcoholics Anonymous group) and were concerned with how people first enter into situations or environments dominated by communities of practitioners already well versed in the rules, tasks, and skills those communities require of them, and the process by which they eventually become practitioners themselves.

### Conceptual Overview and Discussion

Newcomers to communities of practice initially engage with them as novices (i.e., their participation is peripheral, but legitimate nonetheless as they are accepted initially as newcomers into the group) and they set about engaging in small tasks and peripheral activities, becoming familiar with them and acquiring along the way the skills and knowledge necessary for becoming fully fledged and socially recognized practitioners themselves. This is dependent on observing the activities of experts, and listening to them and learning from them, which is why the examples and case studies of various forms of apprenticeship serve to illustrate Lave and Wenger's arguments well. To be distant from an expert is to be cut off from the knowledge and tools of that expert, and so learning is ineffective. Newcomers must first begin from a position on the periphery of the group—and on the periphery of ideas—and are then gradually drawn into the center of the group as they acquire skills and knowledge and eventually become experts themselves. This form of legitimate peripheral participation is not confined to formal occupations, but to all forms of activity where novices must acquire the skills and vocabulary to participate as effective members; in other words, how they become socialized and accepted into a group as legitimate and effective members. Lave and Wenger argue that we are all involved in communities of practice, whether it is at home or at work, because we engage in processes of situated learning no matter how formal or informal they may be, or how much commitment is required of us. Thus,

learning to play a sport is also about participating in a community of practice where rules and specific skills, as well as the formal language and vocabulary that also define the activity, mean as much as physical ability if one is to learn a sport and to play and participate in it well.

Central to Lave and Wenger's idea of the community of practice is the concept of situated learning where learning is by practice and doing, or in other words, through active participation where the newcomer, novice, or apprentice learns by being situated within the social context of the activity and its expression. Wenger went on to develop the idea of learning as being central to human identity, and it is only through effective participation in a community, and through engaging in the social practices of the community, that shared identities are continually produced and reproduced. Our engagement with the world and our understanding of it, Wenger argues, is a "negotiation of meaning" that requires active and vigorous participation in social processes.

### Application

Lave and Wenger's ideas articulate and develop further theories in sociology and anthropology that have a long history, perhaps beginning with van Gennep's *Rites de Passage*, and which can be traced through various ethnographic and theoretical writings about the acquisition of personhood and acceptance into various social groups—in short, how people become social and become accepted as members of groups through social learning. Anthropologist Gisli Pálsson draws on the community of practice idea in his writings about the process of enskilment in the Icelandic fishing industry. Pálsson argues that becoming a fisher entails a process of situated learning in that it takes place on the sea, by being out on boats, finding one's sea legs. Yet he also argues that the highly technical (and also business dimensions) of modern fishing mean that the acquisition of skill cannot be just a matter of being on a boat and watching what seasoned fishers do. It also involves formalized learning in fisheries colleges with formalized accreditation. However, being in a warm classroom on land and being on a boat on a stormy sea are both situations where the apprentice fisher is becoming immersed in a community of practice.

Both are examples of systems of apprenticeship through which novices participate in hands-on activities with seasoned and knowledgeable practitioners. What is important, as Lave and Wenger intimate in their writings, is that these relationships are also reproduced through being essential components of a community of practice. A community of practice is a community within which skilled interaction takes place—learning takes place within the context of relationships with people and with people’s engagement with the world around them.

In *The Perception of the Environment*, Tim Ingold’s work on the dwelling perspective (itself influenced by the philosophy of Martin Heidegger), draws parallels to Lave and Wenger’s arguments in terms of how Ingold sees the person as being inescapably immersed in an environment or lifeworld. Rather than assume that people enter a culture or society to which form and meaning have already been attached, Ingold argues that people continually bring the world into being around them through participation in social and cultural practices. Meaning, argues Ingold, is inherent in the ways in which people engage pragmatically with the constituents of the world. This echoes nicely—and resoundingly—Lave’s own arguments in *Cognition in Practice* that suggest cognition is not something that goes on in people’s heads, but is a social activity firmly grounded in a complex of social relations between people as social beings and the world around them.

### Critical Summary

Lave and Wenger’s ideas have found currency beyond academic concern with learning, knowledge, and skill, and have become particularly attractive to those involved with knowledge management and problem solving in organizations, as well as in education and lifelong learning contexts.

## COMPARATIVE CASE STUDY

---

The comparative case study examines in rich detail the context and features of two or more instances of specific phenomena. This form of case study still strives for the “thick description” common in single case studies; however, the goal of comparative case studies is to discover contrasts, similarities, or patterns across the cases. These discoveries may in turn contribute to the development or the confirmation of theory.

### Conceptual Overview and Discussion

The comparative case study can achieve any of the principal goals of the general case study approach and is not limited in terms of descriptive, exploratory, or explanatory goals. Within this broad context, the comparative aspect of the case study can have either a qualitative or quantitative focus. Comparative case studies tend toward an examination of the typical rather than the outlier or extreme case. Generally, research into the unusual, rare, or revelatory has not been appropriate for multiple-case designs, simply because selected cases must demonstrate enough commonality to allow for comparison.

Robert Yin, who has written extensively on case study research, states that comparative case studies are multiple experiments and not instances of multiple subjects across a single experiment. In case comparison, several cases serve as replication sites for extension or surfacing of theory. Cases may also be viewed as a replication of the instance or phenomenon, similar to an experiment in a quantitative undertaking. These comparisons can be structured as either between-case or within-case studies. Within-case studies, for example, might include several organizations within a specific

industry, cohorts from a particular educational institution, or negotiations between a single country and several allies.

The comparative case approach uses an iterative analysis of each case with final comparison of emergent themes and explanations. The results of each analysis are not pooled, as the strategy is that of multiple experiments, not multiple sampling. Comparison of cases is post hoc in nature, and may be independent of the level of analysis of the case. A longitudinal design is also possible, with one or more instances or sites serving as separate case studies over time. One variation of this is a pilot study, which Robert Yin has used to define an analytical framework and to refine instruments and research tactics.

The case survey is a variant of the comparative case study that views cases chosen for research as a series of data points from which comparison and analysis will be possible. The case survey produces a sample size of hundreds of cases, from which researchers draw out of the detail of their analysis the critical components or factors that are interesting enough to warrant the study. To find comparable sites for this type of research is challenging in any context, and the depth of detail generated through the case survey produces two complicating effects in this form of the case study: increased effort (translating into costs) and the risk of noncomparability due to variations in significant contextual factors. The case survey represents the worst of a quantitative–qualitative mixed approach, particularly when the factor of interest is unduly simplified in order to make volumes of data more manageable.

### Application

The flexibility inherent in between-sites or within-site designs, and longitudinal or cross-dimension designs that presents multiple occurrences is offset by the nearly impossible challenge of finding perfectly matched cases. The use of multiple instances within one organization greatly reduces the confounding effects of different organization cultures and contexts. Cynthia Hardy, Nelson Phillips, and Thomas Lawrence's study of *Mère et Enfant* in Palestine (a small, nongovernmental organization [NGO] that provides nutritional services to women and children in Palestine) is an example of a single organization with several, varying collaborative

partnerships. The examination of each case highlighted particular theoretical categories (e.g., strategic, knowledge creation, and influence effects) that were then drawn together through comparison to define a framework and then extend a tripartite theory of interorganization collaboration.

Special characteristics of a specific case are sometimes obvious only in comparison with others, particularly when cases derive from different contexts. Selection of cases based on population characteristics, dependant or independent variables, and measurement levels is an effective point of departure, depending on whether the researcher is pursuing a most-similar or least-similar design. Notwithstanding the qualitative nature of comparative case studies, history, maturation, and instrumentation effects are all dangers in the case study comparison, particularly in time-lagged, cross-case comparisons. Strategies to overcome these include selecting cases from the same organization, same year, same study, or same context.

Comparative case studies are particularly useful for studying organizational change over time. The longitudinal study by Aimin Yan and Barbara Gray that investigates bargaining power in joint ventures illustrates a number of key aspects of this research strategy discussed above. The authors use various forms of data collection, including interviews and archival data, as well as analytic induction in the analysis of each joint venture case sequentially, making incremental comparisons as coding categories appeared in their data. The study limits cases to manufacturing ventures that are widely representative for the sector and that are comparable in terms of duration and access to informants.

### Critical Summary

Comparative case studies extend the value of the case study approach through iterative model-building and comparison. The case's rich description on a limited number of variables enables a depth of analysis by providing an opportunity to determine patterns in the data that add or extend the theory application, or enrich and refine the theoretical framework. The challenge is to return to the comparative level for final conclusions and to ensure that the framework for comparison is theoretically sound.

## COMPARING THE CASE STUDY WITH OTHER METHODOLOGIES

---

Comparing the case study with the experiment in psychology and the survey in sociology reveals three characteristics of qualitative research: research in natural settings, the development of concepts, and a focus on social process. But compared to other qualitative traditions, the design underlying most case studies is quite structured.

### Conceptual Overview and Discussion

The experiment lends itself to determining the causal effect of a stimulus or treatment; for instance, the effect of a commercial on opinion, attitude, or behavior. The researcher must be certain the experimental factor is present during the experiment and that other factors do not occur during the experiment. Therefore a research setting is artificially created in which a single factor can be manipulated while other factors are excluded. This is mostly realized by matching subjects into pairs and randomly assigning one to the treatment group and the other to the control group. By collecting data from both groups on behavioral and attitudinal variables before and after the treatment, and by

comparing the results, the researcher determines indications of a causal effect of the stimulus on the dependent variable (attitude, behavior).

An experiment is characterized by a large amount of control by the researcher on the research setting (laboratory situation, exclusion of other factors, and induction of a stimulus), the composition of the research groups, and the activity in the research situation (administration of questionnaires, looking at films).

The survey is the most widely used standardized form of sociological research, especially in the domain of public opinion research. The aim of the survey is to obtain information about individual attitudes, values, opinions, circumstances, and behaviors in large populations by using questionnaires. Instead of questioning a population as a whole, a relatively large random sample of the population is drawn as representative, from which inferences are made about the larger population.

The first aim of a survey is a statistical description of the characteristics of a population. Survey data enable researchers to present an overview of the incidence or prevalence of certain opinions or attitudes and to establish relationships with other characteristics or variables such as income, sex, or age. Besides a general overview, following from the distribution of research topics and a statistical elaboration of existing relationships, a more detailed description of specific relationships in segments or subgroups of the larger population may follow. Such a cross-sectional survey representing a population at one certain point in time has limitations for conclusions about change or the causes of differences between subgroups of populations.

The case study is a research design with a long history in the social sciences, especially in those traditions that hold a participative view on social life and organization. Well-known examples are *Street Corner Society* by William Foote Whyte and *When Prophecy Fails* by Leon Festinger, Henry Riecken, and Stanley Schachter. The case study is the basic design for anthropological field work in non-Western cultures, as it represents an extended examination of the culture, or way of life, of a particular group of people.

A case study is an in-depth qualitative research strategy used for a single instance or event, although comparison of several or multiple cases is not uncommon. The case as unit is investigated by

participation in its natural context, for instance a street gang in one neighborhood (Whyte), or one particular sect (Festinger). Participant observation of the natural course of events enhances doing justice to the complexity of the phenomenon under study, that is, the entanglement of distinct elements in the situation. Although many case studies require an extensive exploration of the research setting, most case studies, like all qualitative research strategies, are informed by elaborated substantive and theoretical ideas or concepts.

Based on these global descriptions of three research designs, more specific characteristics of the case study will now be clarified.

### *Naturalness*

Compared to the designs of the experiment and survey, case studies are conducted in the context of real life. Typical of experiments is an artificial approximation of a behavioral setting, which accounts for the main weakness of this design with respect to the external validity of the results. It may be hard to generalize or even translate conclusions beyond the laboratory. Survey designs also do not coincide with everyday life in which people discuss circumstances, exchange opinions, and react to significant others. The interview is an exceptional situation shaped by a stranger (the researcher) by means of a questionnaire. As a design, both experiment and survey concentrate on exact measurement under controlled conditions, as a result of which the contextual meaning of these measurements is secondary.

Choosing the case study design is a choice for maintaining the naturalness of the research situation and the natural course of events. The point of departure is the specific case: Data are collected and analyzed in a way that respects the integrity of the situation under study. As a result, the boundaries of case, phenomena, and context are not clearly evident and must be elaborated within the inquiry itself. Reconstruction of social processes and the elaboration of an analytical framework are two other distinctive characteristics of the case study.

### *Social Process*

The case study design enables close investigation of dynamic social processes as they evolve in

the research setting. A static perspective, on the other hand, is typical of the survey design, in which data collection takes place in a short period of time and it is assumed that changes in social reality did not occur between the first and last interviews. Because processes relate only to the opinions of respondents about changes in their own life, the collected data are perceived as the condition of a population as a whole at one moment in time. The experiment also pays little attention to processes. Although causal effects are the main focus—that is, changes in opinion, attitude, or behavior—controlled laboratory experiments only simulate the social processes involved.

Case studies concentrate on the description of social processes and the explanation of their dynamics. Doing justice to the dynamic character of everyday life is essential when conducting a case study. This can be achieved by participating in the ongoing process and reconstructing the perspectives of the actors involved. The complexity of the situation requires a triangulation of viewpoints and observations. A single perspective is brought together with observations made by the researcher and linked up with perspectives of others participating in the situation or in the background to enable different layers of the situation to emerge.

This causes data collection generally to be longitudinal and mostly extended over several months, and in some cases even longer.

### *Analytical Elaboration*

At the start of the inquiry, the case study researcher lacks a clear vision of the processes involved in the research situation. This makes the point of departure of a case study different from that of experiment and survey. Typical for those designs is a theoretically and empirically elaborated framework based on detailed knowledge from previous research.

To be meaningful, a survey must be founded on prior knowledge of the population to enable sampling, and upon knowledge of existing variations of the phenomena to enable an adequate construction of measurements, and lastly upon knowledge of relevant circumstances and background information.

The experiment is also based on prior knowledge of the population, the stimuli, and other factors influencing the phenomena under study and

how to measure them. Without such knowledge there is no way to know how to match groups or which influences should be eliminated. Apart from theoretical elaboration and derivation of hypotheses, both research designs need grounding in extended empirical knowledge before research is actually conducted.

Case studies start from the opposite direction. First, the researcher must get acquainted with the case, the context and significant processes, to be able to define appropriate procedures and ordering categories. This means that the case study approach consists of several phases of field inquiry and exploration aiming to complement analytical lacunae and to develop methodological procedures. Both this explorative attitude as well as the dynamic character of the phenomenon under study stress the necessity of employing different methods to be able to gain a meaningful and detailed picture of it. The researcher participates in the situation, takes field notes, talks informally with informants, conducts interviews, consults experts in the field, uses archives, and makes inventories of what is going on in the situation. These different data not only allow for different perspectives on the daily course of life, but the data can also correct and supplement each other. By deliberately using different types of information (triangulation), researchers improve the quality of their observations.

### Application

Prototypical case studies are to be found in organization research. Many of these studies have a practical background: a problem that is assumed to be related to the (inter)actions of the stakeholders in the organization. Analytically speaking, the research is focused on the perspectives that guide the actions of all participants on the work floor.

This type of diagnostic organizational research applies a rather structured research design using concurrent explanations of the problematic situation. After a short and intensive exploration phase to produce an inventory of the main units and groups and their perspectives on the problem, observations and analyses subsequently focus on assessing the relevance of the provisory explanations (causes and conditions). Progress in this kind of practical research is stimulated by the use of a research group to speed up observations and

facilitate analytical developments through brainstorming sessions. Many data are produced by using standard instruments. In the course of analysis, comparisons between and within subunits clarify the roles of conditions and elaborate a case-specific theory.

Many case studies have a diagnostic or evaluative objective, mostly related to specific situations in organizations. Others, for instance the study by Leon Festinger, start with an explorative objective to find out what happens to a group when a prophecy, such as of the end of the world, fails. Case studies may also have the objective of testing a hypothesis, as in William Foote Whyte's study of the social structure of a slum. In studies with a more theoretical objective, the case-specific analysis is supplemented by a comparative analysis of strategically selected cases, known as multiple case study, to test the general relevance of the conditions that were found.

Some authors use the term *case study* to refer to all forms of qualitative research. Although all qualitative research subscribes to naturalness, social processes, and analytical elaboration, not all qualitative research aims at developing case-specific explanations. Qualitative research comes in many different forms, three of which are often mentioned as a variety of the case study approach: ethnographic study, life history and biographical research, and grounded theory research.

### The Ethnographic Study

Ethnography aims at reconstruction and description of (an element of) the culture of a social group or society. It is sometimes qualified as an extended case study because of the need for extensive and long-standing participation in everyday routines to master the language and cultural meaning system. Compared to the practical prototype of the case study, the design of ethnographic research is more open as it misses the focus on a specific problematic situation.

The ethnologist tries to gain an insider's view and is free to use every opportunity to discover the principles behind everyday routines. This may be qualified as a process of socialization, making the ethnography a rather personal undertaking. The main research strategy is participation in all kinds of situations, making observations, taking notes

and talking to members, reading documents, or taking photographs. During field work, the researcher mainly writes reflections on the increasing data; the abundance of observations will later be analyzed systematically from different angles defined by the researcher.

### *Life History and Biographical Research*

Case studies of (mostly professional) people aim to illustrate relevant perspectives from participants in problematic situations. The life history approach has its roots in the Chicago School investigations of community life and deviant behavior. A perfect example is the study by William Thomas and Florian Znaniecki of letters that immigrants in Chicago wrote to their families in Poland. The objective of life history research is to illustrate the effects (e.g., changes in values) of general societal processes (e.g., immigration) on the daily lives of participants. Apart from extensive interviewing, data can be drawn from letters, documents, and self-reports as these are produced in their everyday context; they all contribute to the versatility of biographical research.

By supplementing the perspective of the central case with those from participants in the immediate social context and comparing these with other cases and their contexts, these subjective views can be reformulated in terms of a general theory of the problematic situation under study.

### *Grounded Theory Research*

The grounded theory approach aims at formulating theory by extensive study, comparing a relatively large number of cases of a certain phenomena. Grounded theory research starts in an exploratory way with sensitizing concepts that direct the initial observation and analysis. Theory is developed through an iterative process of alternating phases of observation, analysis (coding), and reflection on analytical categories. Core methodological principles are theoretical sampling of new instances of and constant comparison of all situations within a relevant category to test, correct, or redefine the developing theory.

Because the research objective expresses an analytical focus on the development of *general* concepts and substantive theories, grounded theory

research deviates from the case study design that aims at description and explanations that are specific for the case in relation to its context.

### **Critical Summary**

Typical for case study methodology is that research is conducted in a real-life context and that investigations produce a case-specific theory of the natural development of the processes involved. Although case study research may start with the objective to test specified hypotheses, the greater part of these studies focus on diagnosis or evaluation of situations in a specific organizational context. They are informed by elaborated theoretical concepts and substantive ideas, and use standard instruments for quantitative measurement as well as qualitative data gathering methods.

The case study can therefore be considered one of the most structured qualitative research strategies: essential exploration followed by focused data collection and analysis.

---

## COMPLEXITY

---

*Complexity* refers to the level of social organization of a particular integrated system under investigation. Complexity means more than just a “complicated” organization or pattern of endeavor. Complex phenomena cannot be understood by examining their constituent parts using simplistic reductions. Complex cases are “alive,” purposeful, dynamic, evolving, spontaneous, adaptable, unpredictable, and self-organized. Dennis Sumara and Brent Davis describe complex cases as having an integrity that transcends their components.

### Conceptual Overview and Discussion

To be understood in any profound way, a case must be examined organically, taking into account the complex systems in which it is nested. A “complicated” case, in contrast, can be disassembled, understood with sufficient knowledge of its components, and then reassembled without disturbing its functioning. A strength of the case study approach is its ability to holistically investigate complex social events and to examine broadly based complex systemic sets of causes and effects. Reality is complex, and the case method has the ability to deal with the full variety of evidence that a researcher may collect in order to peek into an intricate and unique social system.

Complexity is also a set of concepts that attempts to describe this intricate and particular level of organization, integrating biological, cognitive, and social dimensions of examination. It is a theoretical perspective and methodological approach to vibrant, complex, and unstable systems, their conditions, interrelationships, and spaces.

Complexity theory contributes several useful theoretical perspectives that can assist researchers employing a case approach. As Robert Stake argues, “issues as conceptual structures” can shape primary research questions in order to direct attention to a case’s complexity and contextuality.

- Groups, communities, and organizations are complex adaptive systems: Complex adaptive systems contain “agents,” which can be people, processes, or computer systems. Agents are able to exchange information with their environment and,

through this exchange, learn, adapt, and change their behavior. Agents interact on a local level, but such patterns are nonlinear, in that small “causes” may have large effects and large “causes” may have small effects. This theoretical lens encourages researchers to focus on the ongoing evolution of people interacting with elements within their environment.

- Systems are composed of a series of complex responsive processes: This refers to the actions of human bodies as they interact with one another so that a person interacts both with the social and, at the same time, with the self. Because these two interactive dimensions happen at once, individual minds/selves form the social while being formed by the social at the same time. Therefore, the social and the individual are the same phenomenon. This concept calls the researcher’s attention to the patterns of relationships and the further patterns of interaction these relationships produce.

- Agents and systems are *co-emergent* and have *co-implicating relationships*: Since individuals and the systems they create are continually learning and adapting, and since the social and the self are formed at the same time through complex responsive processes, individuals and systems are intimately connected and coevolve, mutually influencing their growth and development. Though cases are, as Stake suggests, generally bounded systems, this theoretical perspective highlights the unique reciprocal, interactive exchanges between active agents and the environments in which they are embedded, and the difficulty of definitively stating where the case ends and the environment or context begins.

### Application

Complexity theory contends that only a partial view of any system can be captured. A researcher using a case approach must attend to the conditions in which the system emerges and make sense of the living experiences of interaction. Systems do have elements, but it is the interdependencies and interactions among the elements that create the unique and particular whole. So the researcher using complexity needs to examine and illuminate the interrelationships and interdependencies among the elements, including individuals, processes, and forms of communication, as well as the unity of the system itself.

The following are additional dimensions to consider when systematically investigating a complex case.

*The Importance of Context and History.* Robert Yin states that a case study is an empirical inquiry involving a phenomenon embedded within its real-life context. Complex systems have a history. They evolve through time, and their past is co-responsible for their present. Patterns of human interaction produce further patterns of interaction. Past history and experiences are added on and therefore potentially shape future trajectory. History includes practices incorporated into a system's patterns of relating, embodied knowledge within networks and nodes, and a sequencing of the system's structural changes. In describing a case's history and context, significant events are important, but understanding also requires paying attention to the configuration of relationships over time as well as the environment in which the system lives.

*Permeable or Open Boundaries.* Complex adaptive systems are open systems. Individuals interact with others in the environment, extending interaction and communication beyond the boundaries of the system. Both the system and the environment in which it is embedded change through these interactions. These changes ripple out, spilling into other systems. Though a case is defined with certain, clear boundaries, researchers should keep in mind that these boundaries are not rigid and static, but porous and bidirectional, and, in a sense, arbitrarily set.

*Nonlinear Dynamics.* Nonlinearity refers to the principle that the whole is not necessarily equal to the sum of its parts, and that a relatively small change can lead to significantly different system states. Since small changes are amplified by feedback loops (input–output circular processes that allow complex systems to change their structure through their own activity), this produces complex patterns of unanticipated consequences that make it impossible to predict long-term behavior. Positive feedback amplifies itself by strengthening the processes that gave rise to it; negative feedback weakens them. For the case researcher this may mean the use of process tracing, proposed by Alexander George and Andrew Bennett, in an effort to examine nonlinear complexity in detail.

*Emergence.* Emergence is the arising of new coherent properties, patterns, and structures when systems undergo a process of reorganization. This bottom-up phenomenon comes from patterns of behavior enacted by agents in an informal network of relationships that continually grows, changes, and adapts to new situations. Agents residing in one level produce behaviors that lay a level above them. Making sense of the dynamic processes that give rise to and sustain evolving complex systems requires going beyond the notion of cause and effect. In emergent systems, global patterns cannot be reduced to individual behavior.

*Spaces of Possibility.* Systems interact in ways that change each of them, resulting in the growth of complexity from relatively simple beginnings. The enlargement of the space of possibility arises from moving toward such complexity. When the case system approaches a far-from-equilibrium state, it is subject to spontaneous and dramatic reorganizations. These points of instability, or bifurcation points, allow the system to branch off into an entirely new state where new forms of order may emerge. For the researcher, this means examining, in depth, the various transitional points within a system's evolution.

*Nodes and Networks.* These are the formal or informal subgroups of individuals that act as interconnections and function as centers of activity. Nodes rapidly come together, separate, and reform in different permutations according to need; networks tend to maintain long-term relationships throughout the rest of the system. Case researchers illuminate the connectivity and the configuration of relationships within these nodes and networks in an effort to map complex responsive processes.

*Webs of Significance.* This phrase, coined by Clifford Geertz, refers to the influence of culture on human behavior and the construction of social systems. Not only do human beings create and modify their culture, but culture also serves to define the social world. We cannot escape our cultures. We create and are suspended in them. The case researcher using complexity theory, therefore, focuses the analysis on an interpretive search for meaning within the relational nodes and webs of complex responsive processes.

### Critical Summary

A complex social phenomenon cannot be understood by reducing it to its parts. Rather, a more holistic approach is called for. Complexity is a theoretical perspective that attempts to respond to this understanding. Case studies viewed through this lens pose a challenge to researchers since cases are dynamic and constantly responding to the influences of culture and environment. Researchers must be mindful of these influences since they are integral to understanding the cases.

## COMPUTER-BASED ANALYSIS OF QUALITATIVE DATA: ATLAS.TI

---

ATLAS.ti, which runs on Microsoft Windows, is a software program designed to support the researcher in the interpretation and analysis of a variety of data sources, including text, audio, and images. Data can be coded, searched, retrieved, codes defined, related codes or documents grouped together, conceptual diagrams of the emerging understanding of the data created, memos written, and tables of numerical data

abstracted and exported to statistical software such as SPSS.

### Conceptual Overview and Discussion

A case study project is created in ATLAS.ti as a hermeneutic unit (HU) that bundles together all relevant data sources, codes, conceptual linkages, memos, and comments. The data included in case study research (e.g., text, audio, video, photographs, diagrams, and maps) are imported into the software and organized, managed, coded, and analyzed in the HU. Data files are referred to as primary documents (PDs). Each PD is numbered in the order in which it is imported into ATLAS.ti—for example, P1, P2. In case study research, where a number of PDs may constitute a case, the numerical ordering of PDs has an important data management function. The PDs for a specific case can be grouped together by importing them concurrently. If all PDs for a specific case are not imported concurrently but are scattered among other PDs, the numerical position of the PDs can be easily changed to group them as cases.

PDs may also be organized by cases using a function called “families.” A family is a cluster of documents or codes or memos. Within-case and across-case clusters of PDs can also be created. For example, in a case study focused on one or more schools, each school may constitute a case. All data related to a specific school can be clustered into a family tagged with the name of the school. The PDs of within-case variables such as teachers and students can be clustered in PD families labeled “Teachers” and “Students,” respectively, separating the PDs according to cases and variables within cases. Across-case groupings can be similarly clustered. Grouping PDs in families facilitates a focus on a specific case and/or a specific variable set, unencumbered by the presence of PDs that do not belong to that case or variable.

In ATLAS.ti, data must be coded to access further functions of the software. Coding refers to the assigning of a PD to one or more codes. A code is a tag or label that best describes the data to which it is assigned. A margin display alongside a text- or image-based PD provides a visual cue of coding as it occurs. There is no margin display for video or audio PDs.

There are at least two types of codes that organize the data: data management codes are mutually exclusive, and describe the characteristics of a PD; for example, “adolescent” or “female.” Characteristics of a PD are often sociodemographic variables. The whole PD is assigned to the relevant data management codes. Conceptual codes assign meaning drawn from the data (inductive) or from theory (deductive), and are generally not mutually exclusive. Segments of a PD (e.g., lines of text, portions of a photograph, seconds of an audio file, or frames of a video) are assigned to multiple conceptual codes.

Codes are organized in a code pane. The “groundedness” of a code refers to the amount of data coded to a specific code. How grounded a code is in the data is indicated by a number immediately next to the code in the code pane, indicating how many times the code has been assigned in the data. A table for all codes illustrating their groundedness can be exported from the software to Excel or SPSS. A definition for each code, to increase coder reliability, can be inserted in the blank comment space beneath the code in the code pane.

Searching for words in text PDs can assist the coding process by quickly finding specific words that may signify a code. Automatic coding makes use of the word search function to assign words-in-context to one or more codes automatically. The context (a word, sentence, paragraph, multiple paragraphs, or the whole document) can be selected when “scoping” the search. Word search and automatic coding functions cannot be used with nontext PDs such as photographs, maps, audio, and video files.

As coding progresses, relationships among the codes may become apparent. Codes that are related may be grouped together in code families, with each family designating a theme or category. By selecting a specific code family, access is provided to only the codes in that theme or category. Attention can be focused on the codes that constitute the code family without being distracted by other codes. An in-depth, focused analysis of a case by a theme can be facilitated by selecting the PD family that represents the case (excluding all other PDs) and the code family representing a theme (excluding all other codes and themes).

Code and PD families can be used to delimit or scope a search using the query tool in ATLAS.ti. To make the best use of the query tool for searches,

the PDs must be coded. Assigning PDs to both data management and conceptual codes facilitates the retrieval of data. The clustering of PDs into families allows searches to be limited to a case, as well as to within- and across-case searches. The results of a search are reliant on the quality of coding of PDs. Boolean searches combine, intersect, and subtract coded data. Proximity searches show relationships between coded data such as whether data overlap, enclose, or are near to other coded data. Search and retrieval enables further in-depth exploration of the data.

Writing is an important aspect of case study analysis, and within ATLAS.ti, comments and notes may be written in the form of memos, providing a chronological trail of developing thoughts and concepts. By writing within the software, new comparisons, insights, themes, and relationships between codes may emerge, deepening initial understandings and explanations.

Two types of display in ATLAS.ti that are useful for case study research are matrices or tables, and semantic networks. Matrices of codes, showing coding as number of words or number of times a section of a PD has been assigned to a code, can be exported from ATLAS.ti to a statistical package. The network view tool allows the researcher to assign relationships between codes. Codes and memos are easily imported or created in the network view. Causal, associative, and other relationships between codes can be assigned. New relationship types can be created in the Relationship Editor. An iterative and interactive process of working between network views and the analytic text of memos can lead to the discovery of further relationships, understandings, and explanations.

A hypertext function links selected sections of one PD to selected sections of the same PD and/or other PDs. These links can be traversed by following the symbols denoting hypertext links in the display margin, or can be visually displayed in the network view. Causal, associative, and other relationships between hyperlinked segments can be assigned.

Data can be exported from ATLAS.ti. Output including the text assigned to one or more codes, references to nontext data, PD lists, codes and their definitions, and memos can be brought to screen, sent to file, or printed.

### Application

Vaishali Patel and Anne Riley used ATLAS.ti to organize, manage, and analyze data in a multiple case study examining use of Outcomes Management System (OMS) data in decision making by staff in out-of-home childcare programs. Type of staff and service setting were defined as cases, and cross-case comparison of OMS data usage was undertaken. PDs were grouped according to case and, following coding in the software, reports displaying selections of text assigned to specific codes were generated and read to further the fragmenting of codes. Memos documented emerging patterns, meanings, and understandings. Additional reports of text coded to two or more codes were generated and patterns in the data identified, compared, integrated, and summarized. The authors' reported an iterative and cyclical process of coding, memo development, reports, and further reading of PDs to deepen the case study analysis.

### Critical Summary

ATLAS.ti is a storage, organizational, management, and analysis tool for case study research. A variety of data types can be imported into ATLAS.ti, enriching the study. PDs can be grouped together in cases, and memos and codes grouped thematically, facilitating within- and across-case analysis. Codes are not linked to any other code until the researcher specifically creates the relationship, differing from many software where hierarchical relationships between codes are encouraged. Codes and themes can be easily interrogated in ATLAS.ti, enhancing analysis and the construction of theory.

## COMPUTER-BASED ANALYSIS OF QUALITATIVE DATA: CAITA (COMPUTER-ASSISTED INTERPRETIVE TEXTUAL ANALYSIS)

---

Computer-assisted qualitative data analysis uses computer hardware and software to support qualitative data analysis tasks, including search and recovery of data, representation of data, summarizing and interpretation of themes, and exploration of meanings and patterns found in data. Qualitative data are primarily textual data, for example, newspaper articles, organizational documents, interview transcripts, and narratives. Computer-based analysis of qualitative data can involve two forms of analysis: Quantitative analysis of qualitative data uses computers to count key words or codes and is called computer-based content analysis. Qualitative analysis of qualitative data uses nonmathematical processes to explore data. One specific approach to qualitative analysis of qualitative data is computer-assisted interpretive textual analysis, which explores members' meanings in qualitative data through theoretical sampling, computer software, and expansion analysis of data displays.

### Conceptual Overview and Discussion

Quantitative analysis of qualitative data uses computer technology to quantify qualitative data and to perform content analysis. Computer-based content analysis of qualitative data involves breaking textual data down into segments, then coding or classifying each segment. Researchers then use computer technology to count key words or codes and to compose operational indicators of variables. The quantitative measures are used to test or evaluate hypotheses. This reflects a positivistic paradigm where quantitative variables are created and relations among variables are used in a deductive manner to test or confirm theory.

The second form of computer-based analysis of qualitative data uses qualitative analysis involving nonmathematical processes of interpretation to understand the meanings or patterns in qualitative data. The central task of qualitative analysis is to understand the meaning of the text (i.e., qualitative

data). The process is often inductive and not well structured. Computer technology cannot “do” qualitative analysis of data for researchers because the process is not algorithmic or mechanical and cannot be computerized. Computers do routine, clerical tasks and assist in data storage, searching, and display of patterns in data. But the researcher must interpret data.

Computer technology can assist in qualitative analysis of qualitative data by facilitating basic tasks of qualitative research, including making notes, editing notes and data, coding data, storing data, searching and retrieving particular segments of data, linking data, creating memos about data, and linking these memos to data segments. Software can generate data displays that place selected or retrieved data in condensed or organized formats, and it can help map data graphically. Software can also help researchers draw conclusions, build theory, and write reports. This assistance is done by simplification of routine tasks of data management and creation of data displays to help reveal or confirm patterns in data.

Computer-assisted interpretive textual analysis (CAITA) is a specific form of computer-based qualitative analysis that seeks to understand the meaning qualitative data hold for social actors and to develop “second-order” theory that builds on or subsumes members’ “first-order” theories. The focus is thus on induction or theory building from data. Second-order theory development involves recovering themes and meanings from data, providing thick descriptions of how concepts operate in data, and grounding theory in data.

CAITA uses computers to create textual databases, to do mechanical and clerical tasks related to data coding and retrieval, to support theoretical sampling, and to create data displays for expansion analysis. These processes are elaborated below.

A first task in CAITA is to select data that provide a meaningful corpus or body of information about a phenomenon. Such data may be constituted by an interview or set of interviews, a document such as an organizational report, a series of newspaper articles on a particular topic or incident, the transcript of a public hearing, or a combination of such data. The next task is to create a textual database of the data. This simply means creating a machine-readable electronic data file, one often formatted for specialized software, that

can be subjected to qualitative analysis processes including search and retrieval processes and coding processes.

A more explicit focus for research is then developed. Through reflection, induction, coding of data, or grounded theory the researcher surfaces important themes and issues found in data that are conceptually meaningful. Generally, qualitative data are “coded” by adding tags or labels that can be electronically linked to particular segments of the textual data base. In CAITA, the researcher focuses on locating key words that occur naturally in the text and act as naturally occurring “tags” or codes that indicate themes present in data. Once data are coded, or key words noted, key data passages can be located and interpreted in detail. Data can also be used to ensure that emerging themes and concepts are accurately represented by data.

Data displays are then created using computer software to produce organized, formatted tables that assemble all examples of key concepts at work in the database. These data displays or tables are interpreted using expansion analysis—a fine-grained, hermeneutic process for writing descriptions of how contextual and conceptual features of interest operate in data segments. This analysis links members’ discourse, theories, and concepts to more abstract discourse, theories, and concepts of scholars and thereby inductively creates second-order understandings of members’ first-order discourse or text.

### Application

An example of CAITA is provided by a case study done by Robert P. Gephart, Jr., that explored sensemaking during a public hearing into a fatal accident. The accident involved a leak from an oil and gas pipeline that unexpectedly caught fire and burned five men, two of whom subsequently died.

The researcher was familiar with industry operations and attended a public hearing concerning the accident. Sensemaking became the general focus for the case study since inquiry documents and testimony by organizational stakeholders sought to understand and interpret the causes and implications of the event, that is, to “make sense” of the accident.

The researcher obtained a detailed record of all testimony at the hearing, made field notes of

inquiry events, and obtained inquiry board policies and reports, company documents, and newspaper articles concerning the accident and the inquiry. A textual database was created for these data with particular focus on the 1,765-page record of hearing testimony. The database software provided an index of all words used and offered search, retrieval, and data display functions for all words used. In addition, structural reference codes entered into the database allowed search, retrieval, and display of text in terms of speaker, position, organization, and other important issues.

Careful reflection on the data revealed themes including a focus on why the company failed to “flare” or voluntarily ignite the leak to prevent an unplanned fire. *Flaring* became a key word. A theoretically meaningful sample of testimony was developed by search and retrieval of all discussions of flaring for key groups at the inquiry: management, workers, and the hearing board. Key issues related to flaring were sensemaking, risk, responsibility, and blame for the decision to avoid flaring.

Two types of data display were created. Textual exhibits were detailed segments of data that narrate the disaster and inquiry and focus on flaring. Textual tables were developed containing each line in which a key word occurred in relation to key themes of risk, responsibility, and blame for flaring.

Expansion analysis was written for each data display to show how theoretical concepts operated in data. Sensemaking concepts were employed to understand how risk, responsibility, and blame were used to explain organizational actions. Propositions concerning sensemaking during public inquiries were inductively developed to reflect patterns in data and generalize the case to other settings.

### Critical Summary

Computer technology does not enact qualitative analysis of qualitative data but it can greatly aid such analysis. The common expectation that computers can do qualitative analysis can foster three problems. First, researchers may be so focused on software they fail to learn or use basic qualitative research practices. Second, the ease of computer processes such as search and display or counting of key words may distract researchers from careful interpretation of data. Third, conceptual assumptions and operations of software may constrain the

kinds of analysis performed on data. Alternatively, qualitative researchers may avoid using computers in analysis since they believe computers distort data and interpretations. CAITA can support routine and clerical tasks all qualitative researchers employ. It can also help exhaustively analyze case study data and display significant variations within data. Awareness of the limitations and strengths of qualitative computing can help researchers realize the significant advantages of the approach.

---

## COMPUTER-BASED ANALYSIS OF QUALITATIVE DATA: KWALITAN

---

The computer program Kwalitan, which runs on PC/Windows, originated in the late 1980s, when it was designed at the University of Nijmegen, the Netherlands, as a support tool for students and researchers who were engaged in doing qualitative analyses in the tradition of the grounded theory approach. In the past years Kwalitan has undergone several metamorphoses that have resulted in a new version of the program in which user requests have been incorporated as much as possible. While Kwalitan was developed from the perspective of the grounded theory approach, most of the functions in Kwalitan are so basic and

generic that Kwalitan can also be used when analyzing qualitative material using other approaches.

### Conceptual Overview and Discussion

It is becoming inconceivable to perform a qualitative analysis without the use of a computer, especially when having to deal with qualitative material from various sources, as in many case studies. Doing a qualitative analysis implies that a researcher discovers relevant aspects in the material, processes these aspects on a conceptual level, checks the results of this conceptualization against the original material, and makes comparisons between documents/cases. And this process is iterated many times before the researcher is convinced that he or she has captured the content of the empirical material sufficiently on the conceptual level.

In other words, the researcher must constantly switch between the empirical level of the (raw) material and the conceptual level. During this process several techniques are applied, such as several types of coding, summarizing, rephrasing, clustering, categorizing, searching for underlying dimensions, and pattern recognition. These activities can be compared to quantitative techniques such as cluster analysis, factor analysis, or regression analysis, but at a conceptual level, without statistics to help the researcher in interpreting and making decisions. Most researchers would not consider doing these quantitative techniques without the use of appropriate computer support. In the same way, in the case of qualitative analysis, where these analytical processes take place in the minds of the researcher, computer support is indispensable.

Several computer programs have been developed to support the researcher in doing these types of qualitative procedures. Some of these programs are described and illustrated in this encyclopedia. This contribution focuses on one of these computer programs, Kwalitan.

### *The Organization of the Data in Kwalitan*

All original data that have to be analyzed (interviews, documents, observation protocols) and all data that are generated by the researcher during the analysis process (e.g., memos, codes, word lists) are stored in one single file, referred to as the project.

Inside the project, the data are ordered in work files (for different groups of respondents or for different types of data), documents (the interviews or the observation protocols), and segments.

The text of documents is divided into segments (before or during the analysis) by the researcher. A segment is a part of the text that logically belongs together, like a question and its answer, or a paragraph in a document. These segments have several functions during the analysis. To mention two of them: They help the researcher to focus on specific parts in the text, and they function as the coding context—that is, during the coding process they provide the context for interpreting a specific text fragment.

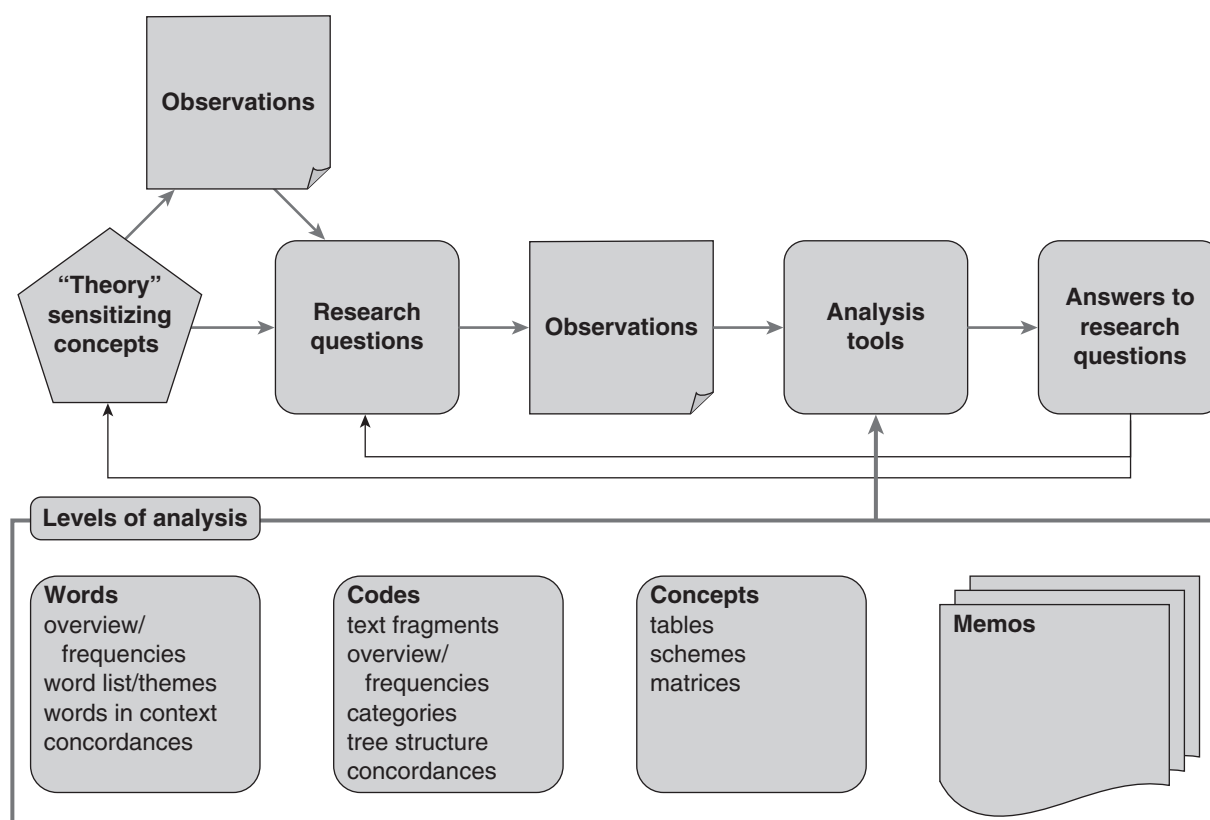

Above it was mentioned that Kwalitan deals with text-based data. In addition, it is also possible to have graphic input (e.g., pictures, political cartoons, art objects) and (short) audio or video fragments as material to be analyzed.

This entry describes some of the features and functions of Kwalitan. It relates them to some of the basic characteristics of qualitative analysis. For a more extended description of Kwalitan, for details about its functions, and for the technical details, readers are referred to the Kwalitan Web site: [www.kwalitan.nl](http://www.kwalitan.nl) (Dutch) or [www.kwalitan.nl/engels/index.html](http://www.kwalitan.nl/engels/index.html) (English).

### *Levels of Analysis in Qualitative Analysis*

Qualitative analysis is about making inferences on the conceptual level, based on empirical data. This process is steered by research questions. In order to answer the research questions, the researcher may use data and information at different levels:

- The words as spoken in the interview or written in the documents; these data coincide with the empirical level
- The codes devised and applied by the researcher and indicating his or her interpretation of the raw data
- The concepts developed by the researcher based on the codes and capturing central themes and concepts
- The reflections of the researcher on the material, the codes, the concepts, and the process, as written down in memos

**Figure 1** Four levels of data in the qualitative analysis process

Source: Peters, V., & Wester, F. (2007). How qualitative software may support the qualitative analysis process. *Quality & Quantity*, 41, 635–659. With kind permission of Springer Science and Business Media.

At each of these levels, specific tools and functions are required to support the researcher. Figure 1 summarizes the broad outline of a qualitative analysis, shows the four levels of data to be used in the analysis, and indicates a few of the tools.

Kwalitan offers support at all four levels of analysis. These functions are briefly discussed in the next section.

### *Functions of Kwalitan*

#### The Level of Words

Analyzing material at the level of words stays very close by the empirical level, since it deals with raw, noninterpreted material. Content analysis focuses on this level, but also for other types of qualitative analysis investigating the original data may help the researcher to become familiar with the material, identify the specific terms that the respondents use; in addition, it may reveal differences between several documents. This investigation may help the researcher to formulate new research questions.

Kwalitan supports the analysis at this level by providing overviews of the words used, composing lists of important words to be used to compare documents, computing concordances between words, and displaying specific words in their (direct) context (key word in context).

#### The Level of Codes

Codes are the basic elements for many analyses. Codes (also referred to as key words) capture the researcher's interpretation of the text. They come in many types, depending on the phase of the analysis: they may refer directly to elements in the texts, to underlying concepts or dimensions, or to patterns. Codes make a connection between the conceptual level and the empirical level. Their function is on the one hand that they help the researcher in conceptualizing, and on the other hand they provide a means for retrieving data that are related to a specific concept.

Kwalitan has several functions that help in analyzing at the level of words:

- Overviews of codes, indicating which codes occur and in what frequency
- Overviews of text fragments that are linked to specific codes
- Matrices of codes, displaying which codes occur in which segments or documents
- Matrices of concordance, indicating which codes occur in the same segment

Both types of matrices can be exported to an Excel spreadsheet or an SPSS data file for further analysis.

### The Level of Concepts

In the process of conceptualizing, the researcher tries to create a conceptual model of the object under study. This implies discovering the relevant concepts and investigating the relation between these concepts by identifying relevant themes, dimensions, or categories that underlie the individual codes, and the relationships between the categories and concepts. To support these actions Kwalitan has three tools:

- Categories: codes that refer to the same underlying concept or theme are brought together in categories
- Hierarchic tree structure: codes, words, and other terms are ordered in a hierarchic tree, unveiling the complex structure of concepts
- Tables: to summarize what is said in specific documents about a selection of relevant themes to help clarify the concepts further

These tools can be used in either a bottom-up or a top-down way.

### The Level of Memos

The use of memos is stressed by practically all method books on qualitative analysis. Kwalitan supports the use of memos. It offers the possibility to create several types of memos (default types are the concept memos, profile memos, theory memos, and method memos). These memos are easily accessible from all parts of the program, so that the researcher has them always at hand and can always add new information.

Memos are important for storing information, but they may also be considered as the object of analysis. The researcher used memos for writing the results of his or her reflection on the steps and procedures in the analysis; memos are reflections on interpretations and actions. Analyzing one's own memos and their reconceptualization may be very helpful in gaining insight into the data and the results of the analysis. Kwalitan supports the analysis of memos.

In addition to the functions mentioned, Kwalitan has many functions that support the researcher in setting up projects, maintaining the data, making backups, and other features that are necessary to run a qualitative research project.

### Critical Summary

Computer programs like Kwalitan are indispensable for qualitative analysis. The complexity of this type of analysis requires support by a specialized set of tools, provided by, among others, Kwalitan. However, Kwalitan and other computer programs remain only tools. Of paramount importance in addition to computer support is a thorough knowledge of qualitative methodology and its procedures. What good is a tool if you do not know what to use the tool for?

The fundamental problems encountered by qualitative researchers are not in the realm of dealing with computer programs (most are very user friendly), but rather in the methodological background of the analyses. Devising powerful codes, transforming one's initial codes to a more abstract level, using categories properly, and writing good accounts in one's memos requires much more thought and effort than questions like where to find and how to deal with codes, categories, or memos in the program. Practice shows, however, that many (beginning) researchers are concerned about whether they should use a computer program for support, and which program will be the best (or the easiest to handle, or the cheapest). Kwalitan is designed as a supportive program; it is not prescriptive concerning the steps to follow. In fact, that is one of the strengths of Kwalitan (and comparable programs), since it can be applied in a variety of research traditions. But this also implies that the user should have clear ideas about how to conduct the analysis, and that is why methodological knowledge is even more

indispensable than a program for computer-based analysis of qualitative data.

## COMPUTER-BASED ANALYSIS OF QUALITATIVE DATA: MAXQDA 2007

---

Computer-assisted qualitative data analysis (CAQDAS) software has become more common in recent years, with various programs available. Such software programs differ in ways such as the types of data that can be analyzed, how data are coded and managed, and how results are presented visually. Because each program has distinctive features, some researchers have argued it is difficult to declare any one software program superior to others. Rather, what software to use will depend on researchers' specific needs and goals. MAXQDA 2007 is the most recent version of a program called MAXQDA ("MAX" named after Max Weber, the famous German sociologist; "QDA" stands for qualitative data analysis). This software program is for PC/Windows computers and is appropriate for textually based case study research. It provides a means of organizing multiple data sources into

one file and offers multiple ways to analyze and manage data. This entry focuses on describing the main features of the program. Various screen shots of the program can be seen at MAXQDA's Web site ([www.maxqda.com/screenshots](http://www.maxqda.com/screenshots)).

### Conceptual Overview and Discussion

MAXQDA 2007 saves all study documents into a file called a "project." In a project, all files are combined into one data file with the file extension ".mx3." To begin a project, a file name is entered and saved in the desired location, and then all relevant study documents are imported into the project. This system design is described as an "internal database" because all documents are kept together within the program, as compared to an "external database" in which a program connects to data files located outside of its software.

Documents imported into MAXQDA are text based and must be saved in rich text format (file extension of ".rtf"). If an object such as a bitmap picture is embedded in a text file, it will be seen only if a specific option in the software is chosen prior to importing the file. However, MAXQDA's coding capabilities of non-text-based objects is limited (ATLAS.ti can analyze data in graphic or pictorial format).

Once a project's name is saved, the MAXQDA screen appears, with four windows on the screen. The four windows are the program's default interface; however, any window can be closed and reopened when desired. The upper left quadrant is called the *document system*. This window shows the files that have been imported into a project. Given that case study research can involve multiple data sources to analyze a unit of analysis, this system may be particularly helpful because different categories of files, called *text groups*, can be created. For example, there may be a section or text group for in-depth interviews, another text group for newspaper archives, and a third text group for an organization's internal documents.

The upper right-hand quadrant is called the *text browser*. The text browser shows one text file or document (e.g., a transcript) at a time. In this window, codes and memos are attached to segments of text. The text can also be edited if necessary (note: changes made anywhere in the program are automatically saved). A text file is opened by going to the document system window and right-clicking on

its name. Right-clicking opens up a new window, and choosing “open text” results in the text appearing in the text browser window. Within this window, two empty columns will appear to the left of the text. One column is for assigning codes to text segments; the other column is for creating memos.

MAXQDA provides several ways to create and assign codes, which are strings up to 64 characters long (e.g., for a study on caregiving, initial codes might be “withdrawing from friends,” “having difficulty sleeping,” or “leaving work early”). Such codes form the basis for eventual categorization and conceptualization. The assigning of codes to segments takes place in the text browser window, but codes may be created in both the text browser window and/or the *code system* window, which is located in the bottom left quadrant of the screen.

A benefit of MAXQDA is that the coding system and text currently being coded can be viewed at the same time. All codes are listed and maintained in the code system window. As with any software program, it is important to note that codes are created by the researcher rather than automatically created by the software. Coding can be hierarchical; MAXQDA allows for up to 10 levels to be created, thus codes can have subcodes within them. In addition, once developed, codes can be deleted, changed, and moved around within the code system window.

Different colors can be assigned to codes. Colors are chosen in ways that are meaningful to the study. For example, if data have been collected in focus group interviews, different colors can identify different people speaking. Similarly, assorted colored codes may represent diverse emotions or actions. Patterns of colored coding may be analyzed later with MAXQDA’s visual tools, such as *TextPortraits* or the *Code Sequence Viewer*.

As previously mentioned, a column in the text browser window is available for creating memos, which are attached to coded segments. Memos can also be created in the document system window (attached to a document) and code system window (attached to a code). The development of a researcher’s thoughts about issues such as method, categorization, and theorization can be captured in these memos, which form the basis for formal research reports. Right-clicking in a memo column where the memo is to be placed opens up a window in which the memo is then written. Memos can be up to 32 pages long, and options include giving it a

specific name, identifying the author of the memo, linking the memo to specific codes, and dating the memo. In addition, coded segments can be copied and pasted into the memo. Memos are identified in the project by small yellow “Post-it note” symbols. After a memo is created, it can be revised or developed further by right-clicking to reopen it. Simply holding the computer’s mouse over a memo symbol also brings up the memo’s information.

The final window, located in the bottom right quadrant, is the *retrieved segments* window. In this window, coded segments can be compared to each other. To view coded segments, a simple procedure of *activation* is followed. Activation tells the program what codes to examine and from which text files. This process occurs by right-clicking on a text file(s) and a code(s) and choosing “activate” for each one. After activation, all coded segments for the specified codes and text files appear in the retrieved segments window. This window is instrumental for the constant comparison technique, in which multiple indicators of a code are compared to each other to make sure they represent the same concept. Coding consistency can also be checked by comparing coded segments from one code to coded segments for another code.

Additional features assist with descriptive coding, content analysis, data management, printing, visual data representation, and teamwork. For example, with the *attributes* function, descriptive coding is entered in a matrix, and then text files can be activated and analyzed on the basis of certain attributes (e.g., gender, geographical location). The attributes matrix can also be exported into SPSS (Statistical Package for the Social Sciences). Content analysis is performed with the *lexical search* function. Memos are managed in the *memo manager* and can be exported out of the program. Coded transcripts can be printed with their coding identified to the left of the text. Graphical model building occurs with *MAXMAPS*. Finally, a recent advancement is *MAXQDA Reader*, a free software program that allows researchers who do not have the software program to view a project (but not edit it). This is particularly helpful when only some members of a research team have access to the software.

### Critical Summary

Advancements in CAQDAS software have changed how case study analysis can be conducted, and

multiple options are available in a variety of software programs. MAXQDA 2007's user interface results in easy organization of and access to multiple textually based data sources. This program also has numerous options for finely tuned coding, data management, visual data analysis, and visual presentation of findings.

## COMPUTER-BASED ANALYSIS OF QUALITATIVE DATA: NVIVO

---

NVIVO is one of a number of software programs available for the organization, management, and analysis of text, image, and audio data. Data can be transcribed, coded, searched, and retrieved in the software. Memos, cases, attributes, matrices, charts, and models of data can be created during the analysis process, providing a number of useful functions for case study research. It works on a PC/Windows platform.

### Conceptual Overview and Discussion

The NVIVO workspace is organized into three *views*. The *navigation view* allows access to all components of the project. The *list view* provides a list of folders obtained by clicking on a specific button in navigation view. Clicking on a folder provides a list of items within that folder. Clicking on an item within a folder presents the item content in *detail view*, where it can be explored and analyzed.

NVIVO facilitates the use of a variety of data sources including text documents, portable document format (.pdf), and audio, video, and image files. Upon import, a wave file is assigned to each audio and video file. Audio and video can be transcribed after import or an existing transcript can be imported and assigned to the audio or video source. Time codes corresponding to the wave file may be applied to the transcript.

Data sources are coded to *nodes*. A node represents and bears the label of a code, category, or concept, and includes the relevant references to the document source(s). A number of different node options exist in NVIVO. *Free nodes* stand alone; *tree nodes* are hierarchically linked codes, concepts, and categories; *case nodes* group data by specific entities or cases such as individuals or organizations; and *relationships* connect items in the case study. Free and tree nodes may include *in vivo* nodes where the label applied to the node(s) is derived from the words of case study participants. Relevant characteristics or *attributes* such as age, gender, and income can be assigned to case nodes for comparison and contrast within and/or across cases.

Data are assigned to nodes by *coding* conceptually similar selections of text together. Coding can be done manually, by highlighting text, or by framing an image or a time segment of an audio/video wave file and assigning it to a node. Coding can be automated using paragraph numbers in text documents, time codes of audio files, the log rows of a photograph, and/or Microsoft Word heading styles in text documents. A further coding method, *text search*, automatically retrieves and codes specific strings of characters in text documents.

“Scribbles in the margin” and comments on emerging concepts are captured in *annotations* and *memos*. Specific text selections in a document can be annotated. Blue highlight in the document

denotes the annotated text selection. Intended as brief notes, annotations may be read, edited, deleted, and/or reviewed. Memos can be created in the software, or in a word processor and imported into NVIVO. Larger than annotations, memos may capture emerging thoughts about concepts and theories, comment on specific documents or cases, and explain or comment on the use of the software or research methods. Memos stand alone or can be linked to the data and nodes to which they apply.

Within- and across-case analyses are facilitated in NVIVO with a variety of search and retrieval tools called *queries*, enabling the researcher to ask questions, or to test hunches or emerging theory. Queries include Boolean (and, or, not) and proximity (near, preceding, surrounding) searches. They can be previewed to scope the retrieval prior to saving the results, or can be retrieved as a node that, except for matrix queries, can be further coded and/or searched. *Coding queries* search and retrieve all coding at a node or all data assigned to a specific attribute. A more complex coding query will retrieve data coded to multiple nodes and/or by multiple attributes. A *matrix coding query* provides a paired comparison of multiple nodes and/or attributes as a numeric table. Clicking on any cell in the table retrieves the text, visual, and/or audio data from which the numeral was derived. Visual cues to patterns in the data may emerge in a matrix coding query table. A *compound query* retrieves a specific string of characters (words, phrases) and coding to nodes, combining two types of search and retrieval, text search and coding queries. The *coder comparison* query measures the consistency of multiple team members' coding by paired comparison across some or all nodes and/or source data. A Kappa coefficient and/or percentage agreement score between pairs of coders is derived.

Visually displayed data in case study analysis encourage reflection and focus on specific aspects of one or more cases. A check of hunches and theories, clarification of the analysis, pattern identification, and presentation of the study to an audience are also facilitated by visual displays. Data display tools in NVIVO include models, charts, and coding stripes that can be printed and/or exported. A *model* is a semantic map of all or part of the case study. Items such as nodes and documents from the project can be imported into the

modeling tool, and/or new items created by dragging and dropping shapes into the model and labeling them. Models may be static or dynamic, the latter changing with any related change in the analysis. Links between items are constructed in the analysis process, for example, hierarchically linked nodes or relationship links. The *chart* tool provides a visual overview of the analysis in bar graphs and pie, bubble, and radar charts. Coding, nodes, cases, attributes, and matrix queries can be charted. *Coding stripes* display coded source data, useful for tracking coding as it is done and for sharing and discussing coding among team members. Stripes of solid color represent different nodes and provide an overview of the intensity of coding at any selection in the data source. Where two data sources occur side by side in detail view, such as an audio wave file and its transcript, both a solid and a shadow coding display are provided. Solid colored coding stripes denote coding in the specific data source, such as the wave file, while shaded coding stripes denote coding in the second data source, for example, the transcript. A further stripe for coding density sits adjacent to the data source. Gradations from white to gray to black indicate none through to large amounts of coding at any point in the data source. Coding stripes can be shared in hard copy among team members.

NVIVO provides an audit trail of the case study project with the use of summaries that can be exported and/or printed from the software. A *project summary* provides a numerical count of all folders and items in the project, as well as when each item was created and modified, and by whom. A *source summary* gives a numerical coding count from each source document, and the size of the document in words, paragraphs, time segments, or dimensions. A *node summary* provides definitions of nodes written by the researcher, and for each node, a table with type of source, percentage of source document, duration (audio), rows (images), and words and paragraphs (text documents) coded. Summaries of relationships, attributes, and coding can also be derived from the software. Regular use of such summaries provides an audit trail of the case study project.

### Application

Christine Jakobsen and William McLaughlin use an early version of NVIVO software to organize,

manage, and code interview transcripts from their single case study examining cross-disciplinary integration processes in the Interior Columbia Basin Ecosystem Management Project. Although video data collected by the researchers could not be included in the version of NVIVO they used, with the recent update of the software, video can now be coded alongside other data sources. The researchers applied an iterative and inductive coding process. Pattern coding followed descriptive coding to thematically cluster codes. Codes were defined to increase coder consistency. Peer debriefing and member checking increased analytic reliability. Memos were used to reflect on emerging concepts and research processes. All facets of the analysis could be traced back from queries, memos, and nodes to data sources in the software.

### Critical Summary

NVIVO is an organizational and analysis tool for case study research. Hierarchical tree nodes group related codes; free nodes encourage exploration of stand-alone codes. Case nodes reference case data, and attributes describe case characteristics. Case nodes and attributes facilitate within- and cross-case comparisons using the query tools, and visual displays such as matrices and models provide an overview, as well as potential analytic directions.

## CONCATENATED THEORY

---

Concatenation is, at once, a longitudinal research process and the resulting set of field studies that are linked together, as it were, in a chain, leading to cumulative, often formal, grounded theory. Studies near the beginning of the chain are wholly or dominantly exploratory in scope. Each study, or link, in the chain examines or at times reexamines a related group, activity, or social process or aspect of a broader category of groups or social processes.

### Conceptual Overview and Discussion

An enduring criticism of the case study as a social scientific method is its limited capacity for generalizing findings. It is argued that, in a single case, insufficient variety exists from which to form valid generalizations. True, some case studies are not intended to be generalized. An analysis of an important author, politician, community, environmental disaster, or scientific advance, for example, could be mounted for no other reason than to understand the subject of investigation. Here, generalizing beyond the case is of little interest.

Meanwhile, other case studies are conceived of as vehicles for generalization. A main goal of these studies is, through well-designed, in-depth analysis, either to discover a set of tentative generalizations about heretofore unstudied phenomena or to help validate tentative generalizations established in earlier exploratory research. Whichever goal, the problem remains the same: Concatenated research is required to fully validate emergent generalizations and their coalescence into grounded theory.

Where this metaphor of a chain of studies becomes inadequate is in its failure to suggest the accretive nature of properly executed, concatenated exploration. In the metaphor of the chain, each link is equally important. Whereas in scientific concatenation the studies in the chain are not only linked, they are also predicated on one another. That is, later studies are guided, in significant measure, by what was found in earlier research in the same area as well as by the methods used and the samples examined there. Thus each link plays a somewhat different part in the growing body of research and in the emerging grounded theory. Furthermore, the earlier studies only *guide* later

exploration; they do not control it to the point where discovery is constrained by preconceptions.

A long-standing problem in case study research, which it shares with other exploratory methods designed to beget generalizations, is that concatenation only rarely occurs, or if it occurs, the process stops long before completion. There are several reasons for this failure, one of the most important being that neither the idea of concatenation nor its necessity is well understood among exploratory researchers. The term itself, by which awareness of the process and its importance might be raised, is of relatively recent origin, dating to a 1992 paper by Robert A. Stebbins.

It may be said for case studies, as well as other discovery methodologies, that enthusiasm among social scientists for concatenated exploration remains as weak today as it was in 1976 when John Lofland wrote that qualitative researchers have published relatively little about how their inquiries might cumulate or be consolidated into larger wholes. Instead, each of their studies tends to be an individual picture standing more or less alone. He noted that each is informed by a shared perspective, but not by any strict sense of specific contribution to a developing, clearly articulated theory. Part of the problem, Lofland concluded, was a dearth of studies that could be consolidated in this manner. Over 30 years later this lack is still evident.

Exceptions to this indictment do nonetheless exist and should be acknowledged to demonstrate that concatenated exploration is not only desirable but also possible. A collection of experiences in the field, edited by William B. Shaffir and Robert A. Stebbins, contains a small number of examples, each consisting of a short description with bibliographic references. Included here is Steven J. Taylor's concatenated work on persons with mental retardation, which rests, in part, on case studies.

### Application

Retaining the open-endedness of inquiry as it evolves through the concatenation process is a central consideration, especially as the emergent grounded theory becomes, with each passing study, more refined, complex, and conceptually valid. For, in a way, that theory comes to act as a paradigm in itself, albeit one highly reflective of the samples

studied to date. The trick is to ensure that the emerging concepts and generalizations are not, as long as the research approach is exploratory, treated as "givens," as truths no longer needing empirical revision and validation. That is, researchers working toward the goal of concatenation in a particular area will still treat the generalizations that have come down to them from previous studies as tentative, as something they would expect to find given certain conditions (these seem often to be demographic), while remaining on the watch for new or contradictory findings from the present study.

The same goes for the use of generic, or overarching, concepts, which also gain clarity, breadth, and validity as concatenation continues. In fact, for both concepts and generalizations, this is the most effective way to ensure validity of exploratory work, efforts to do so in individual studies being much less convincing. The concepts and generalizations must be embraced tentatively; always considered subject to revision in the face of possible observations warranting such change.

### Critical Summary

Concatenation is a research process and the resulting set of field studies that are linked together in a chain leading to cumulative, often formal, grounded theory. To the extent case studies are conceived of as vehicles for generalization, concatenated research is required to fully validate emergent generalizations and their coalescence into grounded theory. Unfortunately, concatenation only rarely occurs, or if it occurs, the process stops long before completion.

---

## CONCEPT MAPPING

---

Concept mapping is a technique for representing a set of concept meanings that are unique to a specific subject. These concept meanings are pictorially arranged on a map that consists of a network of nodes and links. The concept meanings are placed in the nodes while words to describe the relationship between nodes are placed on the links. Joseph Novak defines a *concept* as a perceived regularity in events or objects designated by a label. A concept is a word, phrase, or term used to express an idea.

### Conceptual Overview and Discussion

The concept map is a tool that was developed in the 1970s by Cornell University professor Joseph Novak in his research course for organizing and representing knowledge. Concept maps allow their creators to identify visually what they know about a concept and how the ideas related to the concept are connected. The theoretical underpinnings for the tool are based on David Ausubel's assimilation of learning theory. This theory is based on the proposition that meaningful learning and recall take place through the assimilation of new concepts and ideas into what is already known by a learner, that is, into the conceptual framework that the learner already holds. Ausubel refers to this process as meaningful learning; new ideas or concepts are linked with previously acquired knowledge. One of the goals in the development of concept maps is to promote meaningful learning.

Either an individual or a group of people can produce a concept map. Concept mapping can be done for several purposes: to generate ideas, to design a complex structure, to communicate

complex ideas, to aid learning by explicitly integrating new and old knowledge, and to assess understanding or diagnose misunderstanding. The holistic visual representation of a concept and the fact that information can be presented in a quick and easy manner on one page are two of the advantages to concept mapping. Concept mapping is also a visual tool that can be used to explain and present a complex concept in fewer words than if text were used.

Concept map construction requires a series of steps that lead to a visual representation of a person's knowledge and comprehension of a subject or concept. The process of developing a concept map has been compared to brainstorming. The "mapper" begins with a specific topic and then identifies all the key concepts that are related to the subject. The next step in the process is to place the concepts on the map. The concepts are portrayed in text boxes, often referred to as nodes. The text boxes are linked together using lines. The lines can be labeled with words, propositions on the links that identify the relationship between two text boxes. Usually arrows are used to demonstrate the direction of the link. The mapmaker may find, as the map progresses, that not all of the concepts that were originally identified are relevant or connected to the subject matter. Concept maps can be drawn by hand or completed using a computer software program.

Prior to developing a concept map, a choice must be made as to which type of map best matches the subject matter. Concept maps have been categorized and described in various ways in the literature. There are four basic types of concept maps. *Hierarchical* concept maps start with the most important information on the top and present information in a descending order of importance. *Spider* maps start with the central theme in the center with subthemes and concepts shown as radiating outward from this center. These maps may depict both the hierarchy and the interrelatedness of the concepts. *Flowchart* concept maps organize information in a linear fashion that represents cause and effect. The *systems* concept map, the last basic type of concept map, organizes information linearly, and has inputs and outputs that differentiate it from a flowchart. There are also three specialized concept maps: pictorial or landscape, multidimensional/3-D, and Mandala/

Mandala. In the latter, information is presented within a series of interlocking geometric shapes.

Sometimes concept maps are referred to as mind maps. The main difference between a concept map and mind map is that a mind map involves one main concept while a concept map may involve several concepts.

### Application

A concept map is a visual tool that is used to design and communicate complex ideas and structures. It is used for a brainstorming session wherein the creator writes down whatever he or she thinks is connected to the main idea. Concept maps also can be used as meaningful teaching and learning aids. Christina DeSimone, in a 2007 article, identified three major uses of concept maps in postsecondary learning: the linking and organizing of ideas on paper, the mental construction of concepts, and the electronic construction and exchange of concept maps between students. Concept maps have been used in higher education since the 1980s; they are now becoming an important teaching tool in other disciplines, such as medicine, science, and nursing. In addition, researchers find the concept map a helpful tool to assist with data management, and businesses and governments find that it is a valuable tool for schematically representing conceptual or procedural knowledge.

In 2005, Ian Kinchin, Frans De-Leij, and David Hay investigated the use of concept mapping by undergraduate microbiology students to integrate course material and how the map could be used to evaluate course material. In a similar study in 2008, Dario Torre, Barbara Daley, Tracy Stark-Schwetzer, Singh Siddartha, Jenny Petkova, and Monica Ziebert did a qualitative evaluation of medical students' learning when concept maps were used. Both sets of researchers found that there was support for using concept maps to assist in knowledge integration and critical thinking.

In 2007, Simone Conceição and Linda Taylor performed a review of nursing literature and found that there were three ways that concept mapping was being discussed in relation to nursing. There were articles that focused on research, those that focused on the process of creating concept maps, and those that discussed the use of concept maps in nursing education. They also found that concept

maps were being applied in skills laboratories, classrooms, clinical practice, curriculum development, and research.

Researchers have used concept maps in the planning of a research project, to develop a conceptual framework that will link identified concepts to the actual research. In 2002, Barbara Daley used concept maps to plan a research study investigating how the use of concept maps impacted the learning of adult students in higher education. She charted the eight principles of the scholarship of teaching and learning on a concept map. The actual research was then linked to the eight principles as they appeared on the concept map.

Concept maps also have been used to address the challenges of analyzing qualitative research. Concept maps allow researchers to reduce the data in qualitative research in a meaningful way. They provide the researcher with visual identification of themes and patterns, a strategy for categorizing or coding the data in qualitative research, and a way to present findings. In a 2004 study, Jason Brown and Lisa Bednar used concept mapping to describe the themes identified by parents of children living with fetal alcohol spectrum disorder. In 2004, Patricia O'Campo, Jessica Burke, Geri Lynn Peak, Karen McDonnell, and Andrea Gielen used concept maps to illustrate the neighborhood domains that affect the prevalence, perpetration, severity, and cessation of partner violence. The major disadvantage in using concept maps in research, identified by Barbara Daley, is the complexity of the maps. The format of the concept map can create a challenge for the reader when trying to determine which concepts are of lesser or greater importance.

In nursing, concept maps have been used to develop, individualize, and organize a patient's plan for care. In a 2000 article, Patricia Schuster reported that when nursing students used concept maps to develop patient care plans, the students described the map as a holistic picture of the patient's problems that changed and evolved over time. For the students, the map presented the inter-relatedness of the patient's problems, interventions, and expected outcomes.

Nursing educators have used concept maps as an effective tool to promote meaningful and effective learning and to help students develop abstract and critical thinking and problem-solving skills. Knowledge gains meaning when it can be related

to a framework of existing knowledge. Concept maps can help facilitate the transition from theory to practice. Li Ling Hsu advises that learning is more likely to occur when information is presented in a meaningful way that promotes linking the old and new information or concepts. In contrast to relying on rote memory, the creation of a concept map involves an understanding of the concepts, a connection between the concepts, and a grasp of the entire situation. Novak reports that when concept maps have been used to promote assimilation of new knowledge, students' test scores have increased and there has been a decrease in students' test-taking anxiety.

In a 2005 study, Willie Abel and Martha Freeze evaluated the use of concept maps as a clinical teaching-learning activity. She found that as students progressed through the curriculum, their ability to use nonlinear thinking to identify relationships among concepts increased. Two years later Melanie MacNeil did a similar study, which demonstrated that when concept maps were used to evaluate students' knowledge of course material, students provided a clearer understanding of the material than when traditional course survey methods were used. MacNeil advised that future research is needed to refine evaluation criteria for concept mapping so that it can be used as an effective teaching strategy.

In a 2006 study, Laura Clayton conducted a literature review to identify research studies that used concept mapping as a teaching-learning tool. Her goal was to find evidence for the use of concept mapping as a teaching-learning method. Clayton identified seven research studies upon which to base her findings and recommendations. She concluded that concept mapping usually has positive effects on academic performance and fosters students' critical thinking ability. It also appears that concept mapping may be an appropriate teaching method but, like MacNeil, Clayton warns that the existing studies are limited for drawing generalizations. In a 2007 study, David Hay developed criteria for three types of student learning: deep learning, surface learning, and non-learning. In a master's level research course, Hay used a concept map to assess the quality of learning using these criteria. He found that deep, surface, and non-learning can be directly observed by using the concept map. Hay concluded that concept maps

have considerable potential for tracking student learning but warns that future research is needed to validate the learning criterion.

In 2006, John Nesbit and Olusola Adesope completed a meta-analysis of experimental and quasi-experimental studies that examined students from elementary to university, and from domains such as science, psychology, statistics, and nursing, that learned by constructing, modifying, or viewing node-linked maps. The authors found concept mapping was "somewhat more effective for retaining knowledge than studying text passages, lists and outlines" (p. 434) across a broad range of educational levels, subject areas, and settings. Like MacNeil and Hay, these authors identified the need for additional concept map research.

Concept maps have been used in curriculum planning as they can provide an explanation of why a particular concept is worth knowing and how it relates to theoretical and practical issues both within the discipline and without. Concept maps present, in a highly concise manner, the concepts and principles that need to be taught and the desired outcomes. The mapping process can help faculty members identify key concepts that are to be developed and integrated into the curriculum. At the course level, the instructor can construct a map that incorporates the key concepts and content, teaching strategies, and task allocations for the course. Concept maps can help teachers design units of study that are meaningful, relevant, pedagogically sound, and interesting to students. Using a concept map, faculty, administration, and staff can visually depict the conceptual relationships used for intended program and course outcomes. Overall, concept maps support a holistic style of learning.

Organizations and governments have used concept maps in different aspects of program development, planning, and evaluation. In 2004, the Hawaii Department of Health used concept mapping techniques to identify factors that affect individuals' behaviors related to tobacco, nutrition, and physical activity and to assess patient satisfaction. The Centers for Disease Control and Prevention used concept mapping to develop a logic model for their research program. Tamara Davis in 2007 used concept mapping to conceptualize and assess cultural competence for children's mental health services. Concept mapping

also has been used in engineering as a communication tool and by a newly formed community foundation to facilitate the development of transparent governance.

### Critical Summary

There are a variety of uses for concept maps, but to date their most frequent use is by educators to increase a student's conceptual and critical thinking skills. Research is providing support for the use of concept maps in teaching and learning environments. The fact that concept maps are based on an established body of theory provides additional support for the tool in academic settings.

## CONCEPTUAL ARGUMENT

---

Because case studies generate very rich qualitative and quantitative data, they can be one of the best ways to develop conceptual arguments that result in theory development or extension, as long as sufficient attention is paid to research design. One of the approaches used to develop theory from case studies is called inductivism. Although theoretical propositions can be generated from a single case study, a much stronger conceptual argument can be made with a multiple-case study research design.

### Overview and Discussion

A case can be considered an experiment, capable of producing theoretical propositions that allow predictions to be made about the circumstances under which similar or contrary findings might be expected. Case studies excel at answering “how” or “why” questions about contemporary real-life phenomena, where the researcher has no control over events and the relationships are complex and unfold over time. Case studies are frequently used to generate theory when little is known about a phenomenon, or findings are contradictory or in conflict with common sense, but they can also reveal limitations of, or extend, existing theories, and can provide insight about typical, extreme, or deviant phenomena.

According to Robert Yin, who has written extensively on case study research methodology, ruling out threats to internal and external validity to produce credible findings requires rigorous case study research design. The research design establishes the roadmap for how the study will be conducted, so that causal inferences can be made. It covers what questions to study, what data to collect, and how to analyze results. To make a convincing conceptual argument using a case study, the case(s) must be selected purposely to generate maximum insight into the phenomenon of interest. Data collection should be guided from the outset by tentative hypotheses or propositions that identify plausible, potentially significant relationships and constructs.

To enhance the reliability of the study findings, a research protocol must be established in advance

that sets out, for each of the questions to be addressed, what procedures will be followed for data collection, analysis, and record-keeping. It must be flexible enough to permit the investigation of unexpected findings. The procedures outlined must be followed throughout the study. A database of researcher notes, documents, tables, and transcripts should be created. As well, to make replication possible, a separate evidentiary base that links the study questions and conclusions should be maintained. Evidence must be kept separate from interpretations.

To collect high-quality data, it is imperative that data collection be guided by preliminary theory or, if no theory exists, by a clear explanation of what is to be explored and why, and how the success of the study will be demonstrated. Data should be collected from multiple theoretical perspectives and data sources, using a variety of methods, and, where possible, multiple researchers. This approach to data collection is known as triangulation. Robert Yin states that triangulation provides “between methods” validation, which increases internal validity because measures are independent, and “within methods” validation, which increases reliability by providing assurances of consistency. Obtaining converging evidence via triangulation aids in theory development. Collecting both qualitative and quantitative data can help clarify relationships between variables, overcome researcher biases and blind spots, and prevent unsubstantiated theorizing. Data collection should continue until new data yield few additional insights.

One unique aspect of case study research is that data collection and analysis occur simultaneously. Although data collection is initially guided by tentative theories, as the data are collected continuous comparisons are made between the data and the guiding theory that may reveal anomalies and unexpected findings. Researchers must be attentive to all data collected and must consider all possible explanations for any anomalous findings, including validity threats, researcher biases, competing theories, and changes in the internal or external environment that could have an effect on the phenomenon of interest. They must be prepared to modify their data collection procedures, add data sources or additional cases, and even alter the research question as required by the emergent data.

The possibility that rival explanations might account for study findings poses a serious threat to the credibility of any conceptual argument being advanced. Therefore analytic strategies that minimize threats to internal and external validity are necessary. Robert Yin identifies a number of these. The first is pattern-matching, also called process tracing, where emerging patterns in the data are compared with those predicted by theory, to see if they match. The second is explanation building, where causal linkages to the phenomenon of interest are established over time, as plausible explanations are successively rejected until a credible pattern emerges. A third method is time-series analysis, where changes in a single or in multiple variables over time are noted and compared to trends predicted by theory or rival explanations. Multiple cause-effect chains can also be established and compared to those predicted by theory.

It is highly recommended that at least two case studies are used to build conceptual arguments, because the findings of the initial case can be stated as hypotheses or propositions, and tested in successive cases. The successive cases are purposely chosen to replicate or not replicate findings, as predicted by theory. Each case should be analyzed separately before findings are compared across cases. Each case can be considered an experiment, capable of verifying the theoretical linkages proposed. The use of a multiple-case research design strategy alleviates many of the concerns that might otherwise exist about the nongeneralizability or lack of internal validity of case study findings.

Case study findings must be clearly written and carefully presented to ensure that the conceptual arguments made are credible. The stringency of the design and research protocols, if followed, should ensure credibility, but the case study report itself must be persuasive. Evidence should be supplied in an unbiased way, allowing readers to draw their own conclusions. When writing up single case studies, each theoretical proposition must be clearly presented, with sufficient evidence supplied to support conclusions reached. When writing up multiple case studies, the extent to which theoretical predictions were upheld must be stated, with all instances of nonreplication theoretically justified. In either instance, examining the evidence from different perspectives and demonstrating how rival explanations were ruled out strengthens the report.

## Application

Good examples of how to make credible arguments using case studies can be found in books or doctoral dissertations, where relatively unrestricted page length permits detailed descriptions of the research methodology and the evidence supporting theoretical claims. One example of each is referenced below. There is also a growing body of literature available that pertains to case study methodology. Researchers should find both the Eisenhardt and Graebner and the Yin references helpful. The remainder of this entry describes two recently published journal articles, one a single case study and the other a multiple case study, that made useful theoretical contributions and illustrate some of the ways conceptual arguments can be made.

Darja Peljhan's article describes an in-depth explanatory case study undertaken to examine the relationship between the use of management control systems and strategy implementation in one Slovenian company. Embedding the case study within existing theory, Peljhan collects data from interviews, participant observation, and internal and external documents covering the period 1992–2004. The study illustrates how the two constructs are related, and extends theory by showing how the relationship impacts organizational performance. Her doctoral dissertation is referenced below so interested researchers can access detailed information about methodology and how her data support her conclusions.

In the second article, Elizabeth Hamilton seeks to fill a gap in the literature to arrive at an understanding of how an organization's loss of legitimacy might be connected to its sudden death. By extrapolating from related literatures, an initial explanatory model is created that identifies three possible moderators of the relationship. After stating the tentative relationships as a series of propositions, the propositions are tested by examining archival data collected from company Web sites, business magazines, and newspapers on three purposely selected American companies that suffered sudden death. Each case is analyzed separately, then findings are compared across cases. The conclusion reached is that the model needs revision, but this study makes a theoretical contribution nonetheless by establishing a preliminary model to guide future research and by identifying some of the additional relationships that need to be explored.

### Critical Summary

Proper research design enables researchers to make credible conceptual arguments via the use of single or multiple case studies. Remaining attentive to threats to reliability and to internal and external validity throughout the research process is critical to avoiding the most commonly cited problems regarding case study research. Because case study data are collected holistically and in real-life contexts, and the analytic strategies employed ensure that conclusions reached are tightly linked to empirical data, case studies can produce interesting, empirically valid theory. Situating a case study within the extant literature can strengthen its theory-building capacity.

## CONCEPTUAL MODEL: CAUSAL MODEL

---

A conceptual model is a simplification of reality. It is a schematic representation of the core concepts

(the variables) of a research project and of the assumed causal relationships between these core concepts. A conceptual model might prove very useful when using it in a deductive case study approach, in which the researcher develops the assumptions concerning the relationships between the core concepts by basing assumptions on a theory. A conceptual model can also be obtained as a result of an inductive case study approach.

### Conceptual Overview and Discussion

A conceptual model consists of relationships between core concepts. Although a core concept sometimes corresponds to an observable constant, such as “nature” or “organization,” in a conceptual model core concepts refer only to phenomena that can occur in different variations. For example, leadership style is a phenomenon that has different variations, such as “a participatory leadership style” or “an authoritarian leadership style.” Because of this variation, researchers often use the term *variables* to indicate the core concepts of their research. Some variables, such as “sex,” are *nominal* variables, and can be presented only in terms of distinct categories, such as “man,” “woman.” *Ordinal* variables, such as “level of commitment,” can be presented in terms of “more” or “less,” whereas *interval* variables, for example, “age,” have a variation in which the numeric distance between two ranking points can be fixed.

When we consider the *relationship* between core concepts, we refer to a *causal* relationship, in which we differentiate between cause and effect. We recognize a causal relationship in phrases such as “X causes Y,” “X leads to Y,” “the consequence of X is . . .,” “X influences . . .,” and so on. Generally speaking, we define a relationship between two variables X and Y as a causal one if we assume that, as a result of a change in X, a change will occur in Y. For example, we expect a causal relationship between a leadership style and the business’s profits when we assume that a change from an authoritarian style to a participatory style will cause a change in the volume of the profit.

Labeled according to the nature of the assumed effects, three different types of a conceptual model can be distinguished (Figure 1).

A *direct effect* conceptual model suggests that we study the immediate influence of the *independent*

**Figure 1** Types of conceptual models

variable  $X$  (cause) on the *dependent* variable  $Y$  (effect). For example, we expect that intensive smoking ( $X$ ) causes an increase of lung cancer mortality ( $Y$ ).

It is possible that the independent variable ( $X$ ) affects the dependent variable ( $Y$ ) indirectly, via a *mediating* variable  $Z$ . For example, an increase in the level of economic activity ( $X$ ) will lead to a higher quality in the healthcare system ( $Z$ ), and that the latter will increase the population's general state of well-being ( $Y$ ).

It can also occur that there is a direct effect of variable  $X$  on variable  $Y$ , but only under particular circumstances. In this case we speak of a *moderating* effect, because we expect that a third variable  $Z$  modifies the direction or the strength of the direct relationship between variable  $X$  and variable  $Y$ . For example, the level of financial reward ( $X$ ) will have a direct effect on the level of performance ( $Y$ ). However, we expect that this relationship will be stronger for young people than for those who are older. Hence, we expect a moderating influence of age ( $Z$ ). Please note that the moderating variable  $Z$  does not have an effect on either  $X$  or  $Y$ , but only on the relationship between the two variables.

### Application

In the majority of case study research projects, researchers gather information while using a rather inductive research approach, in which they collect data corresponding to a set of loosely connected sensitizing concepts. Nevertheless, well-established conceptual models are used in a growing number of cases studies, particularly in practice-oriented research. A recent example of the use of a conceptual model in case study research was presented by

Melinda Karp and Katherine Hughes, who studied the influence of the so-called credit-based transitions programs (CBTPs) on students' progress in postsecondary educations. A CBTP is a program that allows high school students to take college classes and to earn college credits while still in high school.

Karp and Hughes developed an initial conceptual model depicting the influence of CBTPs on student access to and success in postsecondary education. The core of the conceptual model represents two independent variables (College Course Work and Support Services) that affect two dependent variables (College Acceptance and Matriculation and College Persistence), via three mediating variables (Academic Skills, Success and Motivation, and Social and Procedural Skills). They conducted five in-depth qualitative case studies. Their study demonstrated that the initial conceptual model oversimplified the reality of college preparation. Hence, they refined the model, thus taking into account additional variables, such as High School Coursework and Student Motivation. Future research should be done to test this model empirically.

### Critical Summary

In a deductive case study approach, a well-designed conceptual model helps the researcher to demarcate his or her research subject clearly and to formulate correctly the assumptions made concerning the relationships between the core concepts. However, the majority of case study projects is based on a rather inductive approach. In those cases, it would be more appropriate to use a set of sensitizing concepts.

---

## CONCEPTUAL MODEL: OPERATIONALIZATION

---

To conduct successfully a deductive case study project that has been based upon the construction of a conceptual model, the researcher needs to operationalize the variables of this conceptual model. Operationalization is the development of specific operational definitions of these variables. According to Earl Babbie, the operational definitions will result in empirical observations representing the conceptual model in the real world. Each conceptual model requires adequate operationalization, regardless of its use in qualitative or quantitative research.

### Conceptual Overview and Discussion

Operationalization requires three steps. First, the researcher needs to specify the core concepts of the conceptual model. Second, the researcher needs to determine a set of indicators or topics. Third, the researcher has to formulate an appropriate set of so-called data elicitors.

The *specification* of the conceptual model starts with defining a generic conceptual model. In the generic conceptual model the researcher defines the core concepts of the research project and decides which of these concepts are the dependent,

the independent, and—when appropriate—the mediating or moderating variables.

For example, in a practice-oriented qualitative case study, the researcher aims at giving a clear insight into the influence of job characteristics on the employees' capacity to change. The generic conceptual model (direct effect) consists of the independent variable Job Design and the dependent variable Capacity to Change.

Because the core concepts as such are often too complex, too comprehensive, and too abstract, they need further specification. Based upon a profound study of the relevant literature, the researcher further decomposes each of these concepts into elements that are more unambiguous, less all-inclusive, and more concrete. The researcher unravels each of the core concepts into its dimensions, aspects, or subspects. Subsequently, the researcher selects the dimensions, aspects, or subspects that will be the constituting elements of the research.

The further analysis of the concept Job Design is based upon the five dimensions of the classic *job characteristics model* of J. Richard Hackman and Greg R. Oldham. The researcher focuses on the aspect Work Quantity Autonomy of the dimension Task autonomy. One of the dimensions of the concept Capacity to Change is Commitment. Commitment is decomposed according to Natalie J. Allen and John P. Meyers's model of organizational commitment. The researcher selects the aspect Affective Commitment from the dimension Commitment. Hence, the specified conceptual model consists of the independent variable Work Quantity Autonomy and the dependent variable Affective Commitment.

The final conceptual model includes the formulation of the assumed relationships to be studied. These assumptions, whether expectations or hypotheses, are based on the results of previous research. If previous research shows that the selected independent variable often has the same effect on the dependent variable, the researcher will be inclined to expect the same relationship in this research project. The researcher formulates assumptions for each of the relationships. This set of assumptions finalizes the conceptual model.

The researcher assumes that Work Quantity Autonomy will have a positive effect on Affective Commitment. The expectation or hypothesis reads as follows: An increase in the level of Work

Quantity Autonomy will lead to a higher level of Affective Commitment.

Second, the researcher needs to determine the *indicators* or *topics* of his or her research. Within the context of quantitative research, the researcher will determine a *measurable indicator* (e.g., number of cigarettes smoked a day) for a specified concept (e.g., level of intensive smoking). Qualitative research needs *recordable and not necessarily measurable* topics (e.g., the respondent's self-report regarding the perception of satisfaction after having smoked a cigarette). Based on further reading of scientific literature and a deeper analysis of the research context, the researcher determines indicators for each of the selected dimensions, aspects, or subspects.

The researcher determines the following topics for the aspect Work Quantity Autonomy: the perceived autonomy regarding the Beginning and Ending of the Working Hours, the Work Pace, and Delivery Time. Organizational Pride, Selflessness, and Loyalty should indicate the aspect Affective Commitment.

Third, the researcher needs to formulate a *data elicitor* per indicator or topic that evokes the data and information in regard to the indicators or topics. In quantitative research, a data elicitor is often a question concerning measurable data, such as people's age, or an organization's turnover. It also could take the form of a Likert item in which the respondent is asked to indicate to what extent he or she agrees with a particular statement. In qualitative research, a data elicitor is a set of questions concerning both the selected topics and the relationship between the different topics.

The researcher formulates a set of questions in regard to both sets of topics concerning Work Quantity Autonomy and Affective Commitment as well as concerning the perceived relationship between the two sets of topics.

### Critical Summary

Operationalization of the conceptual model is a vital step that must be taken when designing a deductive case study project, in both quantitative and qualitative research. Without a clear and well-documented operationalization procedure, the researcher's interpretation of the data of his or her research remains in a black box, thus decreasing the necessary reliability of the research results.

## CONCEPTUAL MODEL IN A QUALITATIVE RESEARCH PROJECT

---

When using a deductive case study approach, researchers often choose a qualitative research design in which they develop a conceptual model. The aim of the qualitative research project is to carry out an in-depth analysis of the relationships between the concepts of this conceptual model.

### Conceptual Overview and Discussion

There are major differences between the elaboration of a conceptual model in quantitative and qualitative research projects. These differences concern both the process of *operationalization*, which is the specification of core concepts into indicators or topics, and the selection of the methods of *data collection* and *data analysis*. In a qualitative research project, the set of decisions that a researcher needs to make in the process of operationalization will lead to a set of *recordable but not necessarily measurable* topics.

For example, in a practice-oriented research project the researcher aims at clarifying the effects of two topics, Career Perspective and Sense of Responsibility, of the independent variable Personal

Characteristics on two topics, Illness Awareness and Perceived Impact on Personal Well-Being of the dependent variable People's Illness. The researcher formulates a set of expectations about the relationship between the two sets of topics. For example, in regard to the relationship between Career Perspective and Illness Awareness the researcher expects to find support for the following hypothesis: "People who have a high career perspective possess a lower illness awareness than those with a low career perspective."

Note that none of the topics are directly measurable. The information required in a qualitative research project often concerns complex research topics that are composed of a number of simple and complex, abstract and concrete characteristics. In this case, by reducing the information to numerical scores, as required in a quantitative research project, the quality of the information is also reduced. The researcher needs to gather so-called *thick* data.

The researchers will seek appropriate methods for data collection, such as a face-to-face open interview, participatory observation, or the narrative approach. Whereas a questionnaire is used in quantitative research, in qualitative research the researcher develops a research topic list with data collection guidelines, to be used during the actual data collection activity. These data collection guidelines include an appropriate set of data elicitors to evoke the thick data and information needed. In qualitative research, a data elicitor consists of a set of questions concerning the research topics. In contrast with the data collection method used in quantitative research, the researcher also develops data elicitors pertaining to the *relationship* between the different topics. Data elicitors in qualitative research indicate the topic label, and the question that needs to be answered. They also include examples of clues or probes (e.g., facts, events, and statements) that indicate the occurrence and intensity of a particular topic.

For example, in order to investigate the expectation that "People who have a high career perspective possess a lower illness awareness than those with a low career perspective," the researcher chooses to interview the respondents and develops three sets of data collection guidelines in regard to Career Perspective, Illness Awareness, and the relationship between these two variables.

*Topic:* Career Perspective

*Question:* Does the respondent have a high or a low career perspective?

*Clues:* For example, when the respondent during the interview states that he or she

- sees possibilities for getting a better job in the near future (high)
- wants to stay in this company because he or she does not want to hinder further career opportunities in the long run (high/low)
- is at the end of his or her career path (low)

*Topic:* Illness Awareness

*Question:* Does the respondent have a high or low illness awareness?

*Clues:* For example, when the respondent during the interview states that he or she

- seeks treatment, such as sick leave and medical consultation whenever the first symptoms of illness occur (high)
- waits a few days before seeking medical help in order to find out whether the symptoms will disappear (high/low)
- postpones seeking medical assistance as long as possible (low)

*Topic:* Relationship between Career Perspective and Illness Awareness

*Question:* Does the respondent indicate that there is a relationship between his or her career perspective and his or her illness awareness?

*Clues:* For example, when the respondent during the interview states that he or she

- hardly ever reports to work sick because it might harm his or her career (high)
- hesitates to report to work sick because it might harm his or her career, but not too long (high/low)
- reports to work sick or not, regardless of the possible consequences for his or her career perspective (low)

The application of the selected data collection instruments results in a set of qualitative data that will be analyzed by making use of qualitative data

analysis techniques. When a conceptual model is used, the collected data are prestructured according to the assumed relationships between the concepts of this model. In this case, the data analysis techniques focus on the analysis of the similarities and dissimilarities between the prestructured data.

### Critical Summary

In a deductive case study approach, researchers often carry out a qualitative research project in which they make use of a conceptual model. In a case study, qualitative research is often preferable to quantitative research, since the required information often concerns complex research topics that themselves are composed of a number of simple and complex, abstract and concrete characteristics. However, as in quantitative research, the researcher must operationalize the conceptual model in a transparent and replicable way. He or she should also develop a topic list consisting of adequate data collection guidelines. Both activities are essential to enhance the reliability and validity of the research project.

---

## CONCEPTUAL MODEL IN A QUANTITATIVE RESEARCH PROJECT

---

When using a deductive case study approach, researchers often combine quantitative and qualitative research, and in both types they use a conceptual model. The aim of the quantitative

research project is to produce general information about the relevant issues of the research object. Subsequently, a qualitative research project is often carried out, focusing on an in-depth analysis of these relevant research topics.

### Conceptual Overview and Discussion

In both quantitative and qualitative deductive case study projects, researchers need to formulate their expectations of the assumed relationships between the variables that are presented in the conceptual model. In both cases, they will gather data and information in order to discover the extent to which the assumed relationships might be found in reality.

Of course, there are major differences between the detailed elaboration of a conceptual model in a quantitative and a qualitative research project. These differences concern both the process of *operationalization*, which is the specification of core concepts into indicators, and the selection of the methods of *data collection and data analysis*.

As Earl Babbie and others have argued, in a quantitative research project the decisions a researcher makes during the process of operationalization will lead to a set of *measurable* indicators: a set of indicators that can be converted into quantifiable data.

For example, in a practice-oriented research project the researcher aims at clarifying the effects of two indicators Age and Sex of the independent variable Personal Characteristics on two indicators Duration and Perceived Impact on Personal Well-Being of the dependent variable People's Illness. The researcher formulates a set of hypotheses about the relationship between the two sets of indicators. For example, in regard to the relationship between Age and Duration, the researcher expects to find support for the following hypothesis (in the words of Piet Verschuren and Hans Doorewaard): "Older people are ill longer than younger people."

Please notice that the indicators Age, Sex, and Duration are directly measurable. The indicator Perceived Impact on Personal Well-Being can be measured only indirectly, by means of a transformation into a set of codes.

The researcher selects or develops an appropriate set of data collection instruments. These instruments are designed to gather quantifiable data in the form

of numerical scores in order to allow the researcher to carry out a statistical data analysis. One of the most common data collection instruments in quantitative research is a questionnaire. The set of data elicitors in a questionnaire consists of a series of closed questions with standardized answers; they are meant to evoke relevant information from respondents. Some of these questions directly ask the respondents for numerical data.

For example, the numerical data of the indicator Age can be asked directly (“What is your age?”). The same goes for the indicators Duration (“How many days have you been ill?”). Other indicators need to be transformed into codes. Sometimes, the researcher simply ascribes a numerical code to a particular variation. Another frequently used technique is the Likert item. A Likert item is a statement which the respondent is asked to assess. The respondent indicates his or her preferred answer after having selected one out of a set of fixed answer categories. A set of coherent Likert items forms a so-called Likert scale.

For example, in regard to Sex, the researcher ascribes code 1 to male and code 2 to female. The indicator Perceived Impact on Personal Well-Being is measured by means of a set of Likert items, such as “When I am ill, I feel downhearted and blue,” with the following respondent’s instruction: Please select one of the following five options: I strongly agree, I agree, I am neutral, I disagree, I strongly disagree.

Take note that in quantitative research the researcher does not include in the questionnaire data elicitors in regard to the formulated hypotheses. Whether or not support is found for the hypotheses depends on the results of the data analysis.

The application of the selected data collection instruments results in a set of quantitative data that will be analyzed by making use of statistical techniques. First, data analysis consists of a well-elaborated set of statistical techniques for data diagnosis, such as data preparation, data description, and scale analysis in order to improve the reliability and validity of the research project. Second, the statistical techniques of data analysis focus on testing the formulated hypotheses.

### Critical Summary

From time to time, researchers carry out a quantitative research project in a deductive case study

approach, in combination with a qualitative research. Since in a case study the required information often concerns complex research topics that are composed of a number of simple and complex, abstract and concrete characteristics, a quantitative research project often has a limited scope. The purpose of this research project is to explore the relevant issues of the research project. On many occasions, the quantitative research project is restricted to a descriptive analysis of the occurrence and variation of each of the variables of the conceptual model. Only on rare occasions does the research focus on an explanatory data analysis, which seeks to analyze the correlation between the different variables, in order to test the set of hypotheses.

## CONFIGURATIVE-IDEOGRAPHIC CASE STUDY

---

Configurative-ideographic case study, also commonly known as an atheoretical case study, is one of the five types of case studies delineated by Harry Eckstein. It is a method that selects cases for analysis with the intent to understand the idiosyncratic dynamics of the case under investigation. In its endeavor to understand the dynamics of a specific case rather than to predict the antecedents of a general phenomenon, its focus remains outside the methodological purview to confirm, infirm, or build theory. Instead it seeks to proffer, as Colin Elman and Miriam Fendius Elman suggest, a highly nuanced and detailed narrative of the phenomenon

that does not draw on, in any substantive manner, theory or theory-related variables.

### Conceptual Overview and Discussion

Configurative-ideographic case study tends to be wholly descriptive and entirely bereft of theoretical considerations. Indeed, as Arend Lijphart observes, such case studies are neither determined by established or hypothesized premises nor are they motivated to advance theory in the field through the generation of hypotheses. As such, its contribution to direct theory development—that is, the construction of generalizations—remains absent. It is, as Alexander George and Andrew Bennett describe, thus ontologically opposite of case methods that revolve around theory testing, that is, case methods that attempt to decipher the validity and the scope conditions of various theories.

Scholars adopting a configurative-ideographic case method endeavor to capture a holistic perspective on a given event or phenomenon. Juliet Kaarbo and Ryan K. Beasley note that while this case method requires the evocation of some level of a priori ideas—as do all examples of empirical research—which could be perceived as recourse to theoretical arguments, studies utilizing configurative-ideographic cases are not explicitly grounded in preconceived notions. The data emerging from this method provide the sole basis for describing the phenomenon under study. Thus, there is little, if any, consideration of how one phenomenon relates to another. This has led some scholars to conclude that configurative-ideographic case studies present few benefits beyond their contribution to conceptualizing historical events. Not surprisingly, then, it is historical studies that rely upon primary evidence to construct particular narratives that have most often utilized this specific case method.

As configurative-ideographic case studies do not directly engage with theory-related elements—and, hence, do not epistemologically cohere with the scientific method—they have been much criticized by scholars. Specifically, criticism has been deployed against its lack of methodological sophistication and the reliability and validity of the data that emerge from these studies. However, for the configurative-ideographic case scholar, this line of criticism remains moot. Indeed, the primary aim of such

case studies is exclusively to provide a substantive descriptive analysis, which is viewed as the end itself rather than a means from which to ascertain broader theoretical objectives. It is precisely this fact that differentiates the configurative-ideographic case study from the disciplined-configurative case study that tests theory or invokes extant theory to explain an outcome, or the heuristic case study that, through induction, develops new theoretical variables and hypotheses.

### Application

Due to the fact that they refrain from generalizing and, therefore, do not engage with theory development, social science researchers have largely refused to employ configurative-ideographic cases as a method for ascertaining empirical results. This might be explained, at least in part, as being due to the difficulties associated with publishing articles in scholarly journals that do not overtly provide theoretical advancements to the field. The utilization of such cases should not be dismissed imprudently, however. Configurative-ideographic cases elucidate, in the most detailed and nuanced of ways, the dynamics of a particular phenomenon. In this way, such studies can potentially offer rich description, which can then serve as an analytical site for theory building in future research.

An excellent example of this is found in Karl Weick's pathbreaking work on sensemaking. Weick uses Norman MacLean's comprehensive case study on the Mann Gulch disaster of 1949 to develop and advance theory on organizational behavior. His research illuminates the possibilities for social researchers to draw upon historical accounts of a single atheoretical case to develop or extend theory. Indeed, writing almost half a century after the event occurred, Weick uses the Mann Gulch case to map a new terrain of academic inquiry for the field of organization studies. In sum, while configurative-ideographic cases are not widely used by scholars, they do, at minimum, provide a platform for conceptual enrichment.

### Critical Summary

Configurative-ideographic cases have been obstinately avoided and, at times, denigrated by social

researchers for their failure to develop theoretical insights. Nevertheless, such cases provide rich data for subsequent theory development. To borrow the vernacular of anthropological methods, configurative-ideographic cases offer a source of thick description—they allow researchers to delve into the details pertaining to the “localized” lived realities, social discourses, and the cultural contexts that manifest in a given phenomenon. Accordingly, critical engagement between data emerging from configurative-ideographic cases and conscious endeavors to expand the case study’s conceptual purview can not only develop an alternative methodological trajectory for conducting empirical work, but also can equally impart novel insights to various social research inquiries.

## CONGRUENCE ANALYSIS

---

Congruence analysis focuses on drawing inferences to the relevance of theories from the (non-) congruence of concrete observations with predictions deduced from these theories. In order to be able to draw inferences about the relevance of the theories, it is necessary that the researcher deduce predictions about what he or she can observe according to these theories. This is not, however, to state that congruence analysis starts with theory. The recommendation that the researcher should derive predictions about observations before the empirical work is conducted is justified only as a means to enhance reliability and objectivity. Such a purely deductive approach is necessary if one is interested in evaluating the predictive power of theories with the help of statistical tools for which standardized observations are needed. A qualitative approach would allow for iterative interactions between theoretical implications and empirical indications, thus leveraging the full richness of information present in the empirical case to draw inferences about the relevance of theoretical concepts.

### Conceptual Overview and Discussion

#### *Epistemological Relativism and Theoretical Pluralism*

Practitioners of congruence analysis indicate that empirical findings are strongly influenced by the theoretical lenses employed. Therefore, congruence analysis has a clear affinity for relativist epistemologies, which results in the conviction that empirical research cannot be used to verify or falsify theories but just to provide evidence for the relative strength of a theory by providing understandings and explanations. Congruence analysis is compatible with a broad epistemological spectrum, from radical epistemological constructivism, which accepts no external reality but uses empirical observations as material to demonstrate the power of a theory to create meaningful interpretations, to positivism, which perceives theories as more or less powerful instruments to shed light on an objectively existing reality. A possible consequence for all of these epistemological starting points is to apply a plurality of theoretical lenses in studying empirical cases. This

plurality of theoretical lenses will provide a more comprehensive understanding and/or explanation of a specific case.

### *“Prediction” More Broadly Understood*

Congruence analysis differs from congruence method on the basis of a broader meaning of “predictions.” In congruence analysis, predictions are not limited to the expected covariation between dependent and independent variables. Instead, the predictions derived from theory should be as diverse as possible and should include not only data-set observations (values of independent and dependent variables) and causal process observations (e.g., sequences of events) but also predictions about the most important actors, their perceptions, and their motivations (traces of micro-foundational causal mechanisms) or other fundamental elements of the theory. In order to be able to deduce these kinds of predictions, theories must be conceptually rich. They must go beyond a hypothesis, which just predicts a specific causal relationship between a factor and an outcome.

We can distinguish among three different approaches in respect to the question of how to weight the various predictions/observations when the researcher draws conclusions for the theories from the (non)congruence of predictions and empirical observations. A quantitative approach would count and weigh every match and every mismatch between prediction and observation equally. More qualitatively oriented scholars would argue that some predictions are more important than others. Those who lean toward a positivist understanding of congruence analysis would point to the predicted covariation between dependent and independent variables. It seems, however, that the most consistent approach within congruence analysis would be to give most importance to the conceptual core of a theoretical approach rather than the necessary outcome, given specific values of the causal factors.

### *Semiotics as a Guiding Tool*

Linking abstract concepts to observations is at the very core of congruence analysis. Researchers applying congruence analysis have to invest much more time and intellectual energy (resulting in

explicit and extensive justifications) on this element of the research process in comparison to what is usually done during the operationalization phase in covariance-oriented studies. In covariance-oriented case studies (e.g., large-*N* studies) the focus of reflection lies on the metric qualities of the indicators. In contrast, the only relevant criterion for predictions or indicators within a congruence analysis approach is the concept validity of these predictions, that is, the question of whether the predicted observation really expresses the meaning of the abstract conceptualization correctly. Similar to how mathematical logic helps to guide the drawing of inferences from covariations of factors to the existence of a causal relationship between these factors, linguistics/semiotics can serve as a guide for drawing inferences from concrete observations to abstract concepts (or vice versa). Theory-oriented case study research should be much more reflective on the relationship between concrete observations and the plurality of abstract meanings that can be associated with these observations.

The following studies can be considered examples of congruence analysis, even though they do not use this wording.

### **Application**

Elizabeth Wilson and Arch Woodside undertook a study using an approach they call “degrees of freedom analysis” because they ground their approach on the famous article by Donald Campbell, in which he showed that case studies can overcome the problem of degrees of freedom because they embody a large set of different observations. This can be considered an application of congruence analysis since the study generates a prediction matrix prior to relating it to observations. More important, the study does not aim to verify or falsify a theory, but rather aims to illustrate the strength of specific theories to explain group decision making. Wilson and Woodside develop their analytical technique, which in essence is pattern matching, in order to compare the extent to which four theories of group decision making are manifest in organizations. They start with deducing predictions from four theories of organizational decision making (i.e., rational, bounded rational, political, garbage can) within nine basic decision phases (i.e., problem definition, solution search, data collection,

analysis, use, information exchange, individual preference formation, evaluation criteria, and final choice between alternatives). For every decision phase they formulate two questions and the answers, which would be in accordance with the four theories. For example, in the second phase (search for alternative solutions) they ask the question: Are potential solutions considered simultaneously and are they compared with each other? Whereas the rational model would be confirmed if the empirical observation provides a “yes” to this question, the political model and the garbage can model would be confirmed if the empirical data indicate a “no.” For the bounded rational model the authors deduce an in-between category; they would confirm the theory if the empirical observations indicate that such a simultaneous consideration of solution occurs “partially.” Over all, their prediction matrix consists of 56 predictions. Once this prediction matrix was established, in-depth interviews were held with two or three members of four different buying centers across a university. The qualitative interviews focused on the same decisions (office copiers) but were semistructured and included open questions. In addition to the transcripts of these interviews, the researchers collected other documents with relevant information for the decision-making process. Three “judges” extracted information out of the acquired data that was seen as relevant to the specific cells of the prescription matrix. Next, this information was coded as hits and misses of each theory. Finally, Wilson and Woodside analyzed the results of the congruence analysis of all three judges with the help of statistical tests (chi-square and  $z$ -test). This means the quality of each theoretical model was tested by the fit of its predictions with the empirical observations.

As a next step, the authors compared the strength of the theories in terms of their ability to generate correct predictions. This means that no theory is falsified or verified. This approach indicates that case studies are able to shed light on the relative strength of specific theories. Another specific quality of this approach is that it combines a strictly deductive approach for generating the predictions and the use of well-defined statistical tools for analyzing the congruence between observations and predictions with a qualitative approach for generating and coding the observations/statements.

Furthermore, the authors reflect upon how to improve the “interpretative” part of the research technique because they realize that in comparison to their sophisticated statistical means to analyze the coded data they have not yet used similar sophisticated methods to generate questions. This, if done, would ensure that there is no bias in the tested theories.

An even stronger example of congruence analysis is the well-known work by Graham Allison and Philip Zelikow on the Cuban missile crisis. The authors differentiate three theoretical approaches for decision making in international politics: the rational actor model, the organizational behavior paradigm, and the governmental politics model. For every approach, they discuss the relevant theoretical literature and formulate a “paradigm” that includes the (a) basic unit of analysis, (b) organizing concepts (including microfoundations like the rational choice theory for the first model), (c) dominant inference pattern, (d) general propositions, and (e) typical evidence used within such a paradigm. After each theoretical chapter follows a chapter in which Allison and Zelikow tell the story in a narrative form guided by the theoretical lens developed in the foregoing chapter. As a result, we get three different “cuts” of the Cuban missile crises. With the respective theoretical framework in mind, they focus within their empirical chapters on three research questions: (1) Why did the Soviet Union decide to place offensive missiles in Cuba? (2) Why did the United States respond to the missile deployment with a blockade? (3) Why did the Soviet Union withdraw the missiles? Each narrative reveals a different interpretation of these research questions in the Cuban missile crisis: the rational version focuses on the key interests of the two superpowers behind each decision; the organizational version describes routines and organizational processes that influenced and delayed decisions; and the politics version showed that power and influence struggles within both groups of advisors and subordinates also influenced the course of events. While the link between theory and empirical information is less strict and stringent as compared to the Wilson and Woodside study, the main goal of Allison and Zelikow is not the testing of the (relative) empirical adequacy of theories, but to show the capacity of the organizational behavior paradigm and the governmental politics model to

reveal factors of influence that would not have come to light by the use of rational actor model. In their methodological reflections about their findings, they acknowledge that the apparent explanatory contradictions between the three different cuts are a consequence of using multiple approaches. In other words, the Cuban case study is neither aiming to reveal which theory is right and which one is wrong (falsification/verification) nor does it try to reveal their relative explanatory strength (as does the Wilson–Woodside approach). It tries to reveal the additional insights that one obtains by using complementary theoretical lenses.

### Critical Summary

One of the strengths of case study research is the potential for coming out with novel findings. At the same time, it is important to ensure the validity of the findings from such studies. Congruence analysis helps in sustaining the validity of a study through a process of analytical generalization. Theoretical pluralism helps in obtaining additional insights from the richness of the case study. A key issue to watch for while using congruence analysis is the appropriateness of relevant theories to the concepts being studied. While a technique such as process tracing helps to trace events to unearth causal and microcausal relationships to the eventual outcome, congruence analysis helps to analyze those relationships using the explanatory power of various theoretical lenses. In a way, congruence analysis helps to bridge the gap between the normative predictions and the positive observations.

## CONSCIOUSNESS RAISING

---

Consciousness raising is a critical tool for raising awareness of social inequities. The process centers on elucidating and elevating individual experiences of oppression to public and political spheres. It is the practice of people with a common concern or orienting issue coming together to share their experiences. In these narrative accounts, they empathize with one another's situations, provide support to each other, and identify and codiscover their commonalities. In consciousness raising, the commonalities are connected to the broader societal structures with a view to how these social dynamics perpetuate injustices. In this process, people become empowered. This empowerment may animate them to make changes not only in their own lives but also to organize with others to develop a broader plan to create change in the civic sphere.

### Conceptual Overview and Discussion

Oppressions and our struggles for social justice give rise to consciousness raising. Consciousness raising is a group process whereby sharing one's

experience inspires group members to see their stories as part of a larger societal problem. The awareness process is one of discovery and empowerment. Working from their own personal lived experience, people in the group see beyond an individualistic approach to their issues to understand how their lives are connected through social practices. These social practices are critical in that they continually create individuals' experiences of oppression. Making these analytical connections to the political nature of social injustice and oppression is formative in creating social change.

Consciousness raising is both a concept and a practice with roots most clearly embedded within the feminisms of the 1960s. Consciousness raising has also been central to liberation education espoused by Paulo Freire. Within feminisms, consciousness raising is intimately linked to the theoretical slogan that the "personal is political." What this means is that what one person experiences is a reflection of the social structural order.

The reason that consciousness raising is such a powerful tool against oppressive dynamics is that it decenters the authority of internalized oppression. Once people gain perspective on how they are both a participant in and a resister to their own oppression, they can connect choice or the lack of choice to their experiences. In such a process of exposing and analyzing their oppression, people are able to gain alternative perspectives. It becomes possible to imagine ulterior patterns and other forms for their life. When these insights are organized and mobilized to create social justice in the public sphere, they have a resonance among the populace that has tremendous political power.

Consciousness raising in the context of case studies has several facets that are connected to the type of case study: intrinsic, instrumental, or multiple case study. Intrinsic case studies, as the name implies, are explored for their own merit. Instrumental case studies are examined in the service of an ulterior motive for their potential to enhance understanding of an issue or phenomenon. The case per se is less emphasized than the theoretical insight it might afford. Several cases selected to accomplish such instrumental goals constitute the multiple case study approach.

Consciousness raising may be a primary objective or a secondary outcome of the process in the

intrinsic type of case study. In these projects, it would most likely be part of an interactive research framework using any one of a number of models, including participatory action research, collaborative inquiry, emancipatory research, action learning, contextual action, or any variation on the concept of grassroots, community-based research. The participants are studying themselves or some aspect of their community with the purpose of creating and exchanging knowledge. They may not be focused explicitly on consciousness raising, but it will often be a subsidiary effect of their collective work.

In instrumental case studies, consciousness raising might form part of the knowledge exchange phase of the project, wherein a particular case was selected to illustrate a point or issue. Communication about the project with the community might animate others to see how their own issues are connected to the case. Exchanging knowledge about their situations might inspire the community to mobilize around their shared issues. Translating knowledge into public action would be part of how the instrumental case study illustrates its role in consciousness raising. Consciousness raising does not always inspire civic sphere action, but it has the potential to do so.

### Application

Consciousness raising in the context of case study research means that the participants develop a greater understanding of their lives. They develop a perspective of being able to see their own lives as influenced by the wider societal structures. They also see how they are located within the research question and in turn how this question illuminates the broader social context. In this they develop an analysis of how they are affected by the material conditions in their lives. They may see how the results of the research could be used to change those material conditions and bring about a shift in the experience of others like them. They may see what they might be able to do to change their situation.

To actually accomplish consciousness raising, the participants have to be involved in the research. Ideally, participants would form part of the research team as in any community-based action research paradigm. In these paradigms, they would

be integral in helping frame the research question. They would participate in the design and the approaches to data collection. They may be informants themselves or they may collect some empirical materials. Participants would inform the approaches to analysis and the interpretation of the multiple streams of evidence in a collaborative process. In sharing their understandings with others through a knowledge exchange type of dissemination, consciousness raising among participants can be expanded to a broader community audience. The knowledge exchange format often has an action element built into the purpose of the project. That is, the dissemination to others might envision an extension of the analysis into the community with a goal of a call to action.

Consciousness raising is a process whereby individuals and communities recognize how their individual struggles may not be about only them. They make the analytical connections that there may be systemic reasons for their struggles. For example: the idea of literacy and blindness. The visual sign system creates literacy problems for blind people that the Braille system does not. Even the biological limitation, blindness, does not necessarily cause literacy problems. Rather, it is the way humans have structured literacy that has become problematic.

Similarly, extending this analysis of other forms of ableism, racism, sexism, ageism, and so on, shows how what one person may indeed experience as a barrier is likely exacerbated or even created by how we humans have designed or structured our interactions.

Consciousness raising implies a set of theoretical assumptions about the nature of personal knowledge and how that can be harnessed for social change. The political motive underlying the research may not be discernible or clear at the outset of the project, but it becomes clarified through the research process. This clarification emerges as personal narratives intersect and combine in ways to bring social processes into bas relief. Bas relief is the artistic process by which the figure emerges slightly from its background. In similar process, the personal stories overlap in ways that give rise to a bas relief of social analysis.

To study the development of consciousness raising as a case study, the research team could use a variety of input pathways including individual interviews,

focus group discussions, and document analyses that might include formal and informal documents. Such projects might include a longitudinal study of the participants in a collective or a retrospective account of the process. While longitudinal approaches would have the value of seeing transitions as they occur and of providing a rich empirical base for the work, they are also resource intensive. The retrospective approach has the advantage of being at the end of a process and looking back. Because of the tendency to recall the past in light of the present, some interesting and important areas would likely be missed. A retrospective study would be less costly but also not as likely to deliver the depth of empirical materials that a longitudinal study would.

### Critical Summary

Consciousness raising is a social practice of emancipation from oppressive power dynamics. The collective works through a collaborative and supportive process to learn about and from each other. The awareness process proceeds through identification of the problem or set of problems, location of the contexts of the problems, analysis of the surrounding or enabling conditions for the problem, and group discussion and analysis of ways that things could be changed. Consciousness raising is based on the idea that collective wisdom can inspire and empower people to change social practices.

## CONSENT, OBTAINING PARTICIPANT

---

Researchers are typically required to obtain the prior consent of those people whom they observe or interact with in the course of generating data. Although it may seem to be a mere self-evident practicality, obtaining consent raises complex issues. It can be seen as methodologically problematic in naturalistic studies (i.e., research on quotidian realities), given the Hawthorne Effect, that is, behavioral changes due to awareness of scrutiny. There is also some concern about its impact on participation rates. Beyond methodological pragmatics, however, there are important ethical considerations. In deference to human dignity and integrity, and except in certain special circumstances (see below), research “subjects” must consciously agree to participate in research, and they must do so *freely*. Moreover, for consent to be meaningful, it must be *informed*: Essentially, participants must be told about the nature of the research and its consequences.

### Conceptual Overview and Discussion

Informed-consent prescriptions are outlined in state-sanctioned ethics codes that regulate biomedical and behavioral research. In the United States, a Code of Federal Regulations applies to research undertaken by federal departments and agencies and to all federally funded research. In Canada, institutions must comply with a Tri-Council Policy if their researchers receive grants from one of the three federal funding agencies. Various professional associations, also, have established voluntary guidelines on the subject.

### Core Principles

Despite differences among the various codes, there are core principles that can be summarized here: Potential participants must be told about the research purposes and procedures, including the nature of the involvement being requested of them. These people must also be apprised of any reasonably foreseeable ill effects of that involvement (risks or discomforts), as well as the benefits to themselves or others that will likely accrue. They

may not be pressured to take part in a project or any component of it; they must be allowed, at any time and without reprisal, to withdraw themselves and/or the data they provided. Further, any limits on confidentiality must be made explicit. Finally, participants must be allowed to raise questions and concerns, and be given contact information to facilitate their doing so.

Putting principle into practice is a complicated undertaking that involves many judgment calls. Questions abound. For example, just what information should be conveyed, how much, and by what means? What is the extent of risk, and who should assess it? What constitutes pressure? Conflict-of-interest concerns suggest that matters like these cannot be left to the researcher, and they are not. Federally mandated Institutional Review Boards (IRBs) in the United States, Research Ethics Boards (REBs) in Canada, and similar committees in other jurisdictions are charged with the responsibility of overseeing the process. The ethics-review applications that researchers are obliged to submit to their review committees must cover the topic of informed consent.

In practice, the standard procedure for acquiring participant agreement makes use of the *written consent form*: a prepared statement that participants are given to read and sign prior to becoming involved in a project. Boards tend to favor this consent procedure. Besides the obvious advantage of standardization, the written consent form presents a specific, detailed description that committee members can scrutinize (and, if need be, return for revision). Since signatures testify concretely to knowledgeable agreement, these forms also offer the institution some protection against lawsuits, especially where (as in biomedical research) there is real potential for significant harm.

Written consent forms have, however, been subject to at least two major criticisms. First, critics have argued that they promote goal displacement. Focusing upon forms can lead wary committees to prioritize institutional protection over participant rights. Institutional protectionism fosters language that satisfies legal advisors but is ethically counterproductive. That is, if informed consent is to be more than an expedient formality, researchers must communicate effectively and respectfully, and “legalese” hardly contributes to that end. Likewise, a focus upon consent forms per se can deflect atten-

tion from other consent issues—such as the timing or setting within which the consent process takes place—that can exert undue pressure on participants. Second, insofar as *written* consent affects rapport, it can stifle some kinds of research. Qualitative researchers, particularly those who work with populations outside the Western mainstream, depend on personal relationships with participants for which rapport is essential. Rapport entails feelings of camaraderie based on trust and mutual respect. By introducing a contractual relationship, written consent can undermine these feelings and provoke suspicion. In fact, a request for written consent can signify disrespect and create discomfort, embarrassing those with limited literacy or threatening those whose experience of officials and authorities has been exploitative. In sensitive circumstances, too, written consent can compromise anonymity and assurances of confidentiality.

Although review board tolerance for alternatives varies, in these circumstances researchers have succeeded in making a case for obtaining *oral consent*. Clearly, verbal agreements carry their own mix of advantages and disadvantages. They can, as the saying goes, be said to be worth the paper on which they are printed, though the currency in this instance is legal protection of the institution and its researchers. However, oral consent need not make a mockery of the ethics review process, nor compromise participant rights. Researchers can prepare statements that are substantively comparable to a written consent form. These can be submitted for review, and offered (or read) to potential participants who then respond verbally. (Such documents are also used by others who opt for *passive consent*, where consent is assumed in the absence of explicit objections.)

The route from ideal to practice is fraught with further twists, turns, and pitfalls. There are other important considerations, such as the status of participants. Age and health affect people's capacity to understand, assess, and act upon information. In research with children and legally incompetent adults, consent must be obtained from an authorized third party; and the U.S. Federal Code and Canada's Tri-Council Policy each lists additional stipulations to safeguard participant wishes. Similarly, both codes warn researchers to take special care to ensure comprehension when seeking consent from members of

vulnerable populations (e.g., the mentally ill). The Tri-Council specifically discusses dependency as another relevant factor: Power relations can compromise free choice in some populations (e.g., prison inmates, military personnel, even employees or students). It directs researchers to exercise caution in these circumstances.

### Case Studies

Some difficulties are especially pertinent to case study research. When case studies entail long-term involvement in a field setting, consent can become awkward and cumbersome. For example, a participant observer in an informal group, or even a more formally organized body, may find that members come and go over time. Further, case study research is well suited to an iterative approach, where new inquiries or lines of investigation are allowed to emerge as data are generated and analyzed. This can put researchers at loggerheads with assiduous review boards that demand comprehensive design details (e.g., "the" questionnaire). More generally, there is some concern among qualitative researchers that review board standards, unduly influenced by quantitative and biomedical models, make unrealistic demands on them.

Where obtaining consent is not a reasonable goal, exceptions and exemptions are available. Acquiring consent would be thoroughly impracticable in some settings: where large numbers of people congregate (e.g., a rally) or move through an area (e.g., a shopping mall). Naturalistic observation (participant or not) without informed consent is allowable in such venues, where privacy cannot be realistically expected and the research is inherently nondisruptive or unintrusive. It exposes participants to no more than minimal risk (i.e., comparable to that encountered in the course of everyday life).

Review boards may waive the informed-consent requirement under other conditions as well, so long as participation neither impinges on rights nor threatens well-being. These involve scientific necessity and societal good. First, the researcher must demonstrate that deception is an integral part of the project design—that the research *requires* participant naiveté, and there is no reasonable alternative. For example, a study of how group norms affect individual attitudes would be unworkable if

the participant were told that the consensus of other “members” was contrived to disagree with his. When subjects know they have been party to research, prior erroneous information can and must be corrected through debriefing. Waivers may be given to projects involving more complete deception, where researchers go under cover. This “covert” research must be justifiable in terms of the significant social benefit accruing to it. But since legitimation entails values, covert research can be controversial. For example, while few would contest the practice in studies of racial discrimination, covert research on soft-drug usage might be provocative.

### Critical Summary

The scientific, ethical, and legal implications of informed consent can be intricate and controversial. Researchers would be wise to consult pertinent federal codes and professional guidelines, as well as their institution’s review board policy and practices.

## CONSTANT CAUSAL EFFECTS ASSUMPTION

---

The constant causal effects assumption holds that a causal effect will be the same across units or across time within a unit. In other words, the magnitude of some causal effect does not depend on the characteristics of a unit or of the period in which it receives the treatment. Rather, every unit that receives a treatment will react in the same manner. While the constant causal effects assumption is convenient for the analysis of some cases, it rarely if ever exists in the world. Accordingly, researchers should be very careful to make sure that the effects they attribute to some cause are as precise as possible and only as generalized as can be proven. Three examples below illustrate how a constant causal effects assumption could be violated. It is then explained how constant causal effects assumptions are another method of thinking about external validity or generalizability.

### Examples

Consider the following example. Assume we want to understand the effect of 4 years of university education versus 0 years of university education on future annual earnings. Suppose further that we were able to conduct a randomized experiment in which some individuals were randomly assigned to receive this education (Group 1) and others were randomized not to receive it (Group 2). If we assumed that the causal effects of education were

constant, then we could calculate the effects of a university education by merely comparing the average income of those in Group 1 with those in Group 2. While there may be variance around the mean (i.e., some people within each group make a little more and some a little less), we could calculate some average effect that we would assume to be constant. We could thus make a statement like, “A university education causes an individual’s annual income to increase by \$40,000 per year, on average.” Problematically, this constant causal effects assumption can be very easily violated. For example, assume that within groups 1 and 2 there are two further evenly sized subgroups (Groups A and B). We now have four subgroups (1A, 1B, 2A, 2B). Now, suppose that the observed annual incomes for each group were as follows. Those in Group 1A earn \$100,000 per year. Those in Group 1B earn \$40,000 per year. Group 2A and 2B members earn \$30,000 per year. The causal effect of a university education appears *conditional* on whether an individual is a member of Group A or Group B. While the average causal effect of university education still appears to be \$40,000 per year, it is in fact quite different for those in Group A and those in Group B. After a more precise measurement of outcomes we would say that a constant causal effects assumption does not hold.

A real-life example of such a finding is that of Joanne Katz, Parul Christian, Francesca Dominici, and Scott Zeger. Katz and colleagues examine the effects of an antenatal micronutrient supplement on the birth weight of infants in rural Nepal. Comparing the average birth weight of those infants that received the nutrients and those that did not, they concluded that prenatal nutrients increase birth weight by 40–70 grams. However, they go a step further to determine whether this treatment effect is constant across infants. Instead, they find that the prenatal nutrients have the most beneficial effects for infants that are the most vulnerable. By looking only at average effects, Katz and colleagues would not have revealed the most beneficial causal effects of this treatment.

The constant causal effects assumption is not violated only by assuming that causal effects are constant across units. The assumption can also be violated if causal effects vary over time. For

example, assume that a case study researcher wants to evaluate the relationship between levels of agrarian organization and the potential for democratic revolution in a society. The researcher may first look at the case of a 19th-century revolution and conclude that agrarian organization played a significant causal role in a democratic revolution; that is, a state requires organized agricultural interests in order to make a transition to democracy. It is possible, however, that such an effect would not occur in the 20th century, as media technology, increased levels of general wealth, and increased levels of education dictate that an organized agricultural sector is not necessary for democratic revolution. The researcher who assumed that the causal effect of such an organization was constant could be potentially mistaken in predicting a country would not make a democratic transition because of the absence of such a sector. Alternatively, the researcher could be mistaken by attributing a successful transition to the presence of such a sector. A constant causal effects assumption can often lead to incorrect inferences about the outcome of a future event, or the cause of some past event.

### External Validity and Generalizability

Constant causal effects can also be conceptualized as questions of external validity or generalizable results. A causal effect that is externally valid is not merely one that exists outside of a laboratory, but one that exists when a treatment is administered on subjects who differ substantially in context from the original subjects. The causal effect of organized agrarian interests would thus be said to be externally valid if it explained cases other than the case from which it was inducted. Constant causal effects can similarly be said to be generalizable. A causal effect that is constant can be *generalized* to all similar cases in any time period. If this is not the case, then an effect cannot be said to be generalized, and cannot be said to be constant. Constant causal effects, then, are unconditional. They are therefore quite rare, especially in case study research.

## CONSTRUCTIVISM

---

Constructivism encompasses a variety of intellectual traditions concerned with the social, subjective, cognitive, technological, and linguistic processes involved in the construction of lay and scientific knowledge. These encompass contributions in psychology, psychiatry, anthropology, and education challenging traditional approaches to learning, communication, and change, and traditions in philosophy and social studies of science questioning objectivism. *Constructivism* and *constructionism* as terms are often used interchangeably in the literature, the first term being preferred in psychology and educational studies, the second in sociology. Over the past 40 years, constructivism/constructionism has also been of continuing interest in qualitative social research, alongside increased recognition of the subjective, social, and discursive texture of human experience, practice, and artifacts.

Despite differences, several common themes outline the contours of constructivist traditions. These traditions tend to be skeptical of empiricist foundations of knowledge and of claims of the objectivity and value neutrality of scientific methods. They particularly question the existence of an external and already determined world and social reality, independent of any human knowledge, action, or activity (*ontological realism*). Although focusing on interactions and communication practices, most constructivist traditions question the distinction between (and independences of) a knowing subject and an object to be known. This has been argued on the one hand to conflate

ontology and epistemology, or on the other to subsume ontology into epistemology, as a result. Factual and scientific knowledge are seen as problematic constructions that, depending on perspectives, are viewed as the product of mental processes, technology, and linguistic and social practices or repertoires. The purpose of both lay and scientific knowledge construction is to provide useful, adequate, coherent, stable, or meaningful representations of the world in accordance with particular sets of systemic or sociolinguistic rules and constraints in given contexts.

### Conceptual Overview and Discussion

Two different traditions are distinguishable in constructivist/constructionist thought: the *biological-systemic* approach (including the *French School* of constructivism, the work of the *Palo Alto School*, and *radical constructivism*) and the *sociocultural* approach (including *strong constructivism* and *social constructionism*).

The *biological-systemic* approach draws on Kant's questioning of the sources of knowledge and his argument that a priori categories of thought shape the impressions formed of experience (sense-data). It resonates with early 20th-century concerns of philosophers of science, historians, and ethnologists with the workings of the Mind and materializes the strong influence of evolutionary theory until the beginning of the cybernetic revolution. The biological-systemic approach is accordingly concerned with the mental operations involved in knowing and thinking that contribute to the construction of knowledge and reality in interactive situations between subjects, or subjects and objects.

Jean Piaget and Gaston Bachelard made the earliest constructivist contributions and are regarded as the founders of the French constructivist school. Piaget's *genetic epistemology* is an isomorph of Piaget's earlier psychological work from structures of individual thought to structures of scientific knowledge, which he considers "constructions of the human mind." Piaget's landmark developmental approach to intelligence (*psychogenesis*) from the 1920s onward is a biofunctional answer to the evolutionary problem of the generation of new structures in living systems. It conceptualizes how human intelligence develops, auto-organizes, and

structures itself through the increased differentiation and complexification of individual structures of thought (*schemas*). This is embedded in an adaptive and systemic view of relations of exchange between individual subjects and an ambient environment (what can be known). Knowledge is part of a system of adaptive transformations resulting from the need by individual subjects both to auto-regulate and develop, that is, explore, expand, act upon, and eventually master their environment. The gradual development of more complex, inclusive, and integrative schemes of thought (progress) results from an increased ability by the knowing subject to balance two conflicting dynamics: *assimilation* (a conservative tendency to preserve existing knowledge structures and shape perceptual inputs accordingly) and *accommodation* (which facilitates the transformation of interpretative schemes to take into account constraints of the environment). Such dynamic equilibrium (*equilibration* or *adaptation*) evolves as human thinking and intelligence progressively structure in simultaneous moves of *exteriorization* (through action and sensory-motor experience) and *interiorization*, from an undifferentiated egocentric psychology to more abstract, conceptual, generalized, and objective forms of thinking (allowing causal reasoning to take place). This occurs conjointly with the development of both self-awareness of one's distinctiveness as a subject and objective ways of knowing the world (*realism*).

A historically oriented philosophy of science, *genetic epistemology* attempts to explain the progress of scientific theorizing as a system of evolving relations between forms of thought, in terms of its endogenous history and teleology. Arguing for an "objectifying form of relativism" distinct from skeptical and contingent forms of historical-critical traditions, genetic epistemology sees objectivity as the limit of a series of successive approximations, marking the transcendent progress of reason. Piaget's epistemological constructivism is therefore orthogenic in that it assumes epistemic change to be directional. Scientific thinking is conceptualized as reaching its own points of invariance (objectivity) through *equilibration*, thanks to the progressive integration of scientific theories into larger and more comprehensive constructions (*sociogenesis*) and distancing from subjectivity toward the construction of collective norms of thought (*psychogenesis*).

Parallel with Piaget, Bachelard considers objectivity as a difficult achieved outcome. However, whereas Piaget differentiates between individual subjects and epistemic subjects (the idealized subject of scientific thinking), Bachelard argues against the idea of an unquestionable and immediately apprehended raw material forming a foundation for scientific objectivity. For Bachelard, science never finds its objects as given or as facts—it constructs and "realizes" sets of possibilities. Accordingly, he draws a line between immediate objects (whose form is considered as given, taken for granted, unproblematic, and "recognized" as natural or real) and the objects of scientific discourses, which he formulates as projects (which are cognized, problematic, and relative to a system of conceptual relations that constitutes scientific discourse, coupled with techniques of realization). Bachelard's concept of *epistemological rupture* (influencing Thomas Kuhn's "paradigm shift") embodies this difference in assuming an ontological discontinuity between science and sense perception. The process of realizing or materializing scientific objects, or *phenomenotechnics*, is set to embrace both a scientific "technical materialism" producing the materiality of scientific phenomena (or its objects) through techniques of realization (including experimental apparatuses and theoretical conditions of formation), and an applied rationalism, acknowledging the conditions of their application. Phenomenotechnics challenges the "false opposition" between theory and application by stressing how the creativity of scientific thinking is set to develop new possibilities and produces new realities. In 1994, Jean-Louis Le Moigne summarized the legacy of Piaget and Bachelard for constructivist epistemologies, which he importantly formalized into two hypotheses (phenomenology and teleology) and two original principles: *systemic modeling* and *intelligent action*. Le Moigne also formalized systemics into a methodological approach based around eight axioms, enabling a non-Cartesian and complex formulation of phenomena in line with constructivist epistemology.

Influenced by phenomenology and cybernetics, *radical constructivism* emerged as a theory of knowing in the early 1960s in relation to the *Palo Alto School*, itself shaped by what has been called the Bateson Project (1953–1962) and by the early work of Piaget. Developed by Ernst Von Glaserfeld,

it proceeds from the assumption that there is no way of knowing reality outside the interactive flows of subjective experience. Expanding Bateson's investigation of the construction of scientific explanation as involving the active structuration and abstraction of data, radical constructivism explores the crucial role of fundamental cognitive operations (the selection, distinction, comparison, and connection of elements into information and phenomena) and of repeated methodological procedures in the scientific construction of regularities and causal explanations. Radical constructivism conveys an instrumental and teleological view of scientific knowledge whose value is assessed in relation to its projects, and to how it contributes to organizing "phenomenological experience" into regular and stable patterns (events, rules, types or domains, theories, models, logic) to reproduce results or make viable predictions in relation to action.

Influenced by cybernetics, information theory, and thermodynamics, the Palo Alto School (Ernst Von Foerster, Gregory Bateson, and Paul Watzlawick, in particular) developed a relational view of mind and knowledge in sharp contrast to behaviorist and cognitivist approaches. Contiguous with Piaget's psychogenesis, Bateson and Von Foerster conceptualized individual mental activity as interactive and transformative, but distinctively consider mental operations as functions of differential perception and processing (based on the relative, comparative, and circular evaluation of variations, differences, or changes). Information processing is conceptualized as the continuing comparison of new inputs or events (differences), their descriptions (coded versions of past events), and their effects (transformations) on cognitive activity. Consistent with *radical constructivism* and Piaget's theoretical account of the irreversibility of time, Palo Alto's conceptualization of cognitive activity as a circular and complex process of illimited, relative, and time-dependent comparison of new to previous inputs (operational circularity) offers a self-referential conceptualization of individual cognition without reference to external reality. Such self-reference is also investigated in Francisco Varela, Humberto Maturana, and Niklas Luhmann's *autopoietic* conceptualizations of social systems distinguishing themselves and maintaining difference from their environment through recursive operations and a paradoxical form of "closure."

The Palo Alto School also systematized and enriched Bateson's anthropological analyses of human interactions into systemic models of communication that redefined psychology, psychotherapy, and understandings of social order, adaptation, and normality. Presented in Naven in 1936, Bateson's theory of *schismogenesis* (progressive change in behavior through cumulative symmetrical or complementary patterns of interaction between individuals and groups) anticipates the cybernetic concepts of positive versus negative feedback. Palo Alto scholars later used concepts of feedback, circular causality, hierarchy, and redundancy to study the microdynamics and patterns of interaction at work in the structuring of interpersonal relations and social reality, whether in maintaining existing norms, rules (*homeostasis*), and beliefs system (*self-fulfilling prophecies*) or in generating conflicts and change. The structuring of interpretive processes through interaction and communication, giving meaning, significance, and value to information is conceptualized in terms of coding variety, levels of communication (*indices* of a message), and sequencing (*punctuation*). In 1936, Bateson also began an epistemological and methodological reflection on the role of observers and conceptual forms of thinking in the delimitation of phenomena and the creation of objective orders of reality. This became part of *second-order cybernetics* and radical constructivism. Doubting the validity of his own explanatory categories, he showed skepticism toward human consciousness, always purposive, and the "suspect reifications" characterizing most explanatory methods in social science. Influenced by Russell's theory of logical types, he later developed a four-tier model of learning and the concept of the double-bind, the latter characterizing and explaining the communication paradoxes and conflicting injunctions relating to schizophrenia.

Engaging more widely with the construction of cultural artifacts and social objects, the *socio-cultural* approach emerged as part of the post-Kuhnian sociological turn in philosophy of science and incorporates two main traditions: *strong constructivism* as developed in sociology of scientific knowledge, and *social constructionism* more generally. Both tend to be influenced by the later Wittgenstein on "language-games" and Berger and Luckmann on the social construction of reality.

Published in 1966, Berger and Luckmann's agentic approach to social order introduced the "social construction" metaphor to consider the constitutive role of microsocial patterns of relations in creating and maintaining social structure. Here, social reality is conceptualized as an ongoing human production involving the repetitive ordering of human conduct into patterns and routines (*habitualization*) and their reciprocal and socially controlled typification by legitimate actors (*institutionalization*). A historical and externalized product of institutionalized agency, the objectivity, facticity, and taken-for-grantedness of social structure is legitimized and controlled through socialization. Knowledge about society conveys the ontological objectivity of institutions as social facts. This legitimates their existence to a significant portion of society while, at the same time, obscuring the intersubjective origins of these facts. Social actors then reinforce these institutions through acting in accordance with their objectified character. Berger and Luckmann consequently claim that social processes influence individual perceptions and beliefs about the world (*subjective reality*) that themselves play an important role in the (re)construction of institutions and persons (*objective reality*).

Berger and Luckmann's thesis made way for the development of constructivist approaches to the sociology of scientific intellectual subcultures and practices. From the 1970s, *strong constructivism* (Karin Knorr-Cetina, Bruno Latour, and Steve Woolgar, and Michael Lynch) offered a detailed, microfocused, context-sensitive and case-based approach to contemporary scientific laboratory activity emphasizing its local, contingent, and situated character. The role of discursive practices, inscription devices, human agency, and processes of negotiation in the production of scientific facts and phenomena were scrutinized. Ethnographic observation of scientific methods, procedures of practical reasoning, and inference use to generate data, knowledge claims, and factual knowledge (hypotheses, laws, theories, models, or other kinds of representations) showed their creative, negotiated, and interpretive character. The ambiguity of standard procedures left room for differences in their interpretation, application, and evaluation. This led constructivists to reformulate scientific activity as the artful production and development of discursive

resources and the transactional product of mundane negotiation between different interests in specific scientific subcultures, challenging rationalist and falsificationist conceptions of science. Expanding on Bachelard's phenomenotechnics and emphasizing the "artificiality of the laboratory itself," constructivists also identified how researchers materially produce phenomena and transform them using technology or inscription devices, anticipating results and "making things work" as part of the "machinery of science."

*Social constructionist* traditions, developed by John Shotter, Kenneth Gergen, and Jonathan Potter, following Berger and Luckmann, challenge individualistic and neo-Kantian categories of experience, cognition, or mind (what Gergen calls "the impasse of individual knowledge"). They attempt to move beyond the duality of subject-object and the subjectivist-realist views associated with each of them (which Gergen labels *endogenic* and *exogenic*). *Social constructionism* reconsiders the problem of meaning-making and theorizing from an intersubjective, social, and discursive point of view, focusing on conversational, rhetorical, and representational activities. Language, discourse, and interpretive repertoires are primary devices for the construction of social reality, with words taking meaning in the context of ongoing social relationships. For Wittgenstein, language does not represent the world but represents the "*form-of-life*" through which we engage with the world, as social relations are formed and reformed within language. As habitual, structured, and institutionalized as is social life, language becomes a series of "*language-games*." Social life then inevitably reflects the collective negotiation of multiple realities and their often conflicting interpretations. Potter's work on discourse (talk and text) as social practice examines the rhetorics at play in account and fact construction and explores epistemological implications for objectivation that Berger and Luckmann neglect. He first investigates how descriptions are produced in ways that will enable them to be treated as factual, appearing to be neutral and independent of the speaker, and how they might be challenged or undermined. Second, he considers how descriptions may be involved in action and performance. Like Shotter, Potter is skeptical of theorizing as reified and abstracted narrative construction based on literary conventions and encourages its resistance.

Shotter's *rhetorical-responsive* version of social constructionism, however, mostly emphasizes the situated, relational, dialogical, and embodied character of conversational activities and is more concerned with practical conduct. He utilizes Wittgenstein's ordinary language philosophy and Bakhtin's dialogism to place the emphasis of social construction on the quality of *betweenness* or joint action in the dialectical movement of relationships.

Unlike Potter and Shotter, Gergen embraces both a relativist and a metatheoretical position. His thinking is eclectic, incorporating Ludwig Wittgenstein, Martin Heidegger, Hans-Georg Gadamer, Michel Foucault, and Jacques Derrida. He furthers a critique of the post-Enlightenment impetus toward monologic, asocial, and ahistorical systems of thought and referential, foundational, and representationalist treatments of knowledge. Gergen emphasizes the free-floating semantic character of linguistic predicates in relation to events external to language. He conjointly asserts the communal aspects of language whose meaning is situated in and indexical to historically formed "*living traditions*" (contextual conventions of interpretation, established norms, or usage resulting from socially negotiated agreements). Drawing on developments in poststructural philosophy, Gergen's social constructionism has both a critical and a transformational intent, acknowledging the changing historical discursive character of accounts of self and identity, particularly within psychology, and the ideological texture of scientific production more generally.

### Application

Constructivist/constructionist traditions focus on human social processes and activities that are considered both reflexively transformative and self-sustaining, rather than objective artifacts, things, or substances, as phenomena of interest. Like post-structuralism, constructivism dramatically emphasizes the nonobjective dimensions of scientific investigation (e.g., concept generation, definitional work, explanation, claim-making, argumentation, conflict resolution, interpretation of results, evaluation, and establishment of consensus). It makes the unreflexive use of traditional methodological designs problematic as a result. Researchers engaging with constructivism/constructionism should

face the following methodological issues: the problematic status of empirical data and delimitation of phenomena; the problematic status of the researcher resulting from subject-object interdependency or inbetweenness; methodological relativism; the emergence and contingency of research design; and the problematic ethics of results evaluation. There is no distinctive constructivist/constructionist methodology, however, and, from a qualitative methodological point of view, it can still be difficult to differentiate from interpretivist and ethnomethodological research. Indeed, most constructivist social research was called "naturalistic" before 1990. In spite of their claim of adopting a new paradigm, Yvonna Lincoln and Egon Guba's naturalistic methodological principles for qualitative research hardly stand apart from interpretivism. Contradictions due to selective relativism in assuming constancy in the definition of phenomena to facilitate comparison of cases (what Steve Woolgar and Dorothy Pawluch term *ontological gerrymandering*) have also been identified.

Constructivism and social constructionism are more distinctive as perspectives on methodological issues than methods in themselves. However, typical methods adopted include action-research, conversation and discourse analysis, ethnography, clinical studies and group-based methodologies, reflexive interviewing, and visual and auditory elicitation techniques. The types of cases that they look for result from what they consider to be researchable phenomena.

Biological-systemic constructivists stress the intellectual activity of conscious subjects in their constructive and projective mode. Case studies in psychology and education have investigated learning as problem-solving, and the role of sensory experience, individual reflection, and abstraction in understanding and the construction of causal explanation, conceptual artifacts, and theories. Novice-expert interactions, contexts favoring collaborative work between pairs, and the uses of artifacts have been researched as opportunities for creativity. Systemic and cybernetic modeling offer original case descriptions or simulations of transformative (e.g., invention and design) or regulatory processes in complex environments. Cognitive change or aspects of subjective experience have been studied in cases exploring the dynamics and framing of relations between doctors/nurses and patients in

traditional or transformative therapeutic contexts. Action-research interventions include enlightening cases of co-constructed dynamics of change. Here, the role of the researcher's, teacher's, or therapist's subjectivity and personal creativity in the active constructing of scientific realities, and how this subjectivity should be taken into account from a methodological point of view, are considered.

Sociocultural traditions are concerned with local, conversational, and discursive practices constituting the construction and maintenance of social norms, concepts, and categories (e.g., subjectivity, gender, culture, identity, institutions, deviance) as well as scientific factual knowledge, explanation, and argumentation. Ethnographic research in sociology of scientific knowledge produced case studies of scientific knowledge production in laboratories, while conversation and discourse analyses investigated the rhetorics of factual writing or the politics of scientific consensus and authority. In psychology, social constructionist approaches demonstrated the cultural situatedness and discursive texture of traditionally universal concepts like emotions or perception. More generally, experimental writing incorporating co- and practical authorship, self-reflexive deconstruction of narrative traditions, and a diversity of styles and forms of representation have been encouraged.

### Critical Summary

Constructivism eschews belief in an absolute foundation of human knowledge and ascription of truth-value independent of the determining effects of human social activity. Human action is understood as occasioned in accordance with systemic constraints or sociolinguistic rules rather than determined by scientific laws. Through its investigation of cognitive and sociolinguistic practices, constructivism/constructionism shows the problematic, socially negotiated, culturally, and linguistically bounded status of factual knowledge and explanatory systems of thought, challenging traditional views of the relations between the particular and the universal. However, debates are ongoing about the extent of the relativism practiced (ontological, epistemological, or methodological). Proponents and critics of constructivist approaches raise the issue of the self-refuting character of linguistically

oriented constructivist approaches due to the circularity of language and problems of unbounded reflexivity. Beyond knowledge production, the broad consideration of formative processes can make the construction metaphor difficult to distinguish from other perspectives with which it shares affinities (interpretivism, poststructuralism, critical qualitative inquiry). For instance, social constructionists influenced by critical developments in anthropology have increasingly recognized the politics of field work relations—between researcher and subjects, subjects and other subjects, between researchers, and in wider social contexts because of the inseparability of power and knowledge.

## CONTENT ANALYSIS

---

Content analysis is a tool of qualitative research used to determine the presence and meaning of concepts, terms, or words in one or more pieces of recorded communication. This systematic and replicable technique allows for compressing many words of text into fewer content categories based

on explicit rules of coding in order to allow researchers to make inferences about the author (individuals, groups, organizations, or institutions), the audience, and their culture and time.

### Conceptual Overview and Discussion

Content analysis became a relatively established method of systematic analysis during the 1940s. At first, content analysis was a time-consuming process, executed manually, prone to human error, and subject to serious time and resource constraints. Because of this, the technique was limited to examinations of texts for the frequency of occurrence of identified terms or to short texts, being deemed impractical for more complex investigations, for larger texts, or for most recorded communication other than written texts. By the 1950s, researchers had recognized the need for more sophisticated methods of analysis, and as a result they started to focus on concepts rather than words, and on semantic relationships rather than just the mere presence of certain words.

Since then, content analysis has been extended to almost every type of recorded communication, ranging from books, newspaper articles, historical documents, medical records, Web sites, speeches, and communiqués to theater, television programs, sketches and drawings, informal conversation, writing journals, interviews, classroom discussions, lectures, and manifestos of political parties. As a result, today this research technique is used in fields as varied as marketing and advertising, literature and rhetoric, media studies, ethnography and anthropology, cultural, gender and age studies, sociology, political science, psychology and cognitive science, theology, and religious studies.

Since the 1980s, content analysis has also been widely used in media analysis and media evaluation, often in combination with data on media circulation, frequency of publication, readership, and number of viewers or listeners. During recent decades, various software packages have greatly facilitated the execution of content analysis by allowing researchers to sift systematically through large volumes of data with relative ease, and to make inferences that can then be corroborated by using other methods of data collection and data analysis. Today it is widely recognized that the careful examination of communication patterns can

help researchers learn a great deal about individuals, groups, organizations, institutions, and even the larger society in which they are embedded.

### Application

Content analysis is possible whenever there is a physical record of communication. This record of communication can be (a) created independently of the research process and internally by the individual or organization under study (as, e.g., newspaper articles, or archived documents detailing household consumption), (b) internally generated and externally directed (e.g., the verbatim transcripts of legislative hearings or committee debates generated by a number of parliaments around the world, which may reflect or obscure the political decision-making process), or (c) produced by the researchers themselves in view of the analysis that needs to be conducted (as, e.g., videotapes of television news programs or commercials, or of debates carried out in the legislature and/or town council). The population of available communications greatly influences the nature of the questions that can be answered through content analysis, as well as the reliability and validity of the final research results.

The most basic quantitative content analysis consists of a frequency count of words, although the assumption that the most frequently mentioned words reflect the greatest concerns does not always hold true. A concept's importance might be overestimated when the word has multiple meanings (as when a record includes references to cabinet "ministers" and religious "ministers," and the researcher fails to set these meanings apart). Its importance can be underestimated when synonyms are used for stylistic reasons (e.g., an author uses the name of the president—"Obama"—and "our head of state" in order not to repeat the word *president*) or when the author avoids raising the issue represented by the concept as a result of self-censorship in response to societal bias or political pressure (e.g., the author omits references to current political leaders for fear of censorship).

To avoid such problems, researchers first use frequency counts to identify words of potential interest, and then conduct a Key Word In Context (KWIC) search to test for the consistency of usage of words. Most qualitative research software programs allow researchers to read the whole

sentence in order to see the word in context, a procedure that strengthens the validity of inferences made from the data. Newer software packages, which can differentiate between the different meanings of the same word based on context, have greatly reduced the level of difficulty in conducting content analysis and allowed for ever more sophisticated analyses. In addition, researchers must note that nonstandardized measures can lead to biased results. If, over the Cold War, the Americans uttered a total of 100,000 words, including 100 salient references to weapons' proliferation, while the Soviets uttered 200,000 words, including 200 salient references, one might conclude that the Soviet were interested in the issue more than were the Americans. However, when standardizing the measure to obtain the proportion of all salient words, then we would conclude that both sides were equally interested in the topic. Depending on the recorded communication under analysis, basic content analysis could also include space measurements (column length in the case of newspaper articles or advertisements) and time counts (for radio and television programs).

### *How It Works*

More complex content analysis extends beyond word counts to code and categorize the data. Data are coded with coding protocols decided either before or during the analysis. In a priori coding, categories are established before the start of the analysis. Professional colleagues agree on the selected categories, the coding is applied to the data, and revisions are operated, if needed, in order to maximize the mutual exclusivity and exhaustiveness of the categories. In emergent coding, categories are established after a preliminary examination of the data and during data analysis. In this case, at least two researchers review the material independently and select a set of features for inclusion on a checklist; reconcile any differences between their initial checklists; design a consolidated checklist to apply the coding independently; and finally check the reliability of the coding, aiming for at least a 95% agreement. If the level of reliability is not acceptable, the researchers repeat the process as many times as needed to obtain the desired reliability. If the level of reliability is the one desired, the coding is applied on a large-scale basis.

To construct the categories, words with similar meanings and connotations are organized in mutually exclusive and exhaustive categories, which ensures that no word falls between two categories, all words are assigned to the categories, and the categories do not overlap. The text is broken down into manageable categories that could range from a word or a word sense to a phrase, a sentence, or even a theme, and then it is examined using either conceptual or relational analysis. Conceptual analysis establishes the existence and frequency of concepts represented by words or phrases in a given text. Relational analysis goes one step farther to examine the relationships among different concepts in a given text. Dermot McKeone further differentiated prescriptive analysis from open analysis. While prescriptive analysis emphasizes a closely defined set of communication parameters, which can be specific messages or subject matter, open analysis identifies the dominant messages and main subject matter of a recorded communication.

Coding units can be defined physically in terms of their natural or intuitive borders (e.g., letters, newspaper articles, communiqués, poems, or archival documents); syntactically by using the separations created by the author (e.g., words, sentences, or paragraphs); or referentially by employing the referential units created by the author (e.g., a text might refer to Barack Obama as “our president,” “President Obama,” “the 44th president of the United States” or just “Obama”). In addition, coding units can be defined by using propositional units that result from breaking the text down in order to examine underlying assumptions. For example, a sentence reading “Transitional justice was launched after the new democratic government replaced the dictatorship” is broken down into “The new democratic government replaced the dictatorship” and “Transitional justice was launched.”

Typically, content analysis uses sampling units, recording units, or context units. Sampling units, which can be words, sentences, or paragraphs, are the individual units we make descriptive and explanatory statements about. If we wish to examine novelists who wrote on transitional justice, then the individual writers included in our sample constitute our sampling units. Recording units can be ideas relevant for the analysis. For example, we might want to see if some novelists valued transitional

justice for its ability to reevaluate the recent dictatorial past or for preventing future human rights trespasses. However, in some cases it might be difficult for the researcher to determine whether authors present transitional justice as a backward-looking or a forward-looking phenomenon by simply examining their assertions on transitional justice. In this case, researchers use context units, which allow assertions to be evaluated in the context of the writing. The researcher must decide whether the paragraph around the assertion, several paragraphs, or the entire writing is the appropriate context unit.

Klaus Krippendorf listed six questions that need to be addressed in every content analysis. These questions are: (1) Which data are analyzed? (2) How are they defined? (3) What is the population from which they are drawn? (4) What is the context relative to which the data are analyzed? (5) What are the boundaries of the analysis? (6) What is the target of the inferences? To allow for replication, data examined through content analysis must be durable in nature. Several problems can occur when written documents or other types of recorded communication are assembled for content analysis. When a significant number of documents from the population are missing or unavailable, the content analysis must be abandoned. When some documents match the requirements for analysis but they cannot be coded because they are incomplete or contain ambiguous content, these documents must be abandoned.

### *Use in Political Science*

Some of the best applications of content analysis in the area of political science have included determining authorship, identifying trends and patterns in documents, and monitoring shifts in public opinion. Using Bayesian techniques based on word frequency, in 1964 Frederick Mosteller and David Wallace showed that James Madison had indeed authored the *Federalist Papers*. Three decades later, Don Foster used statistical methods to identify Joe Klein as the anonymous author of *Primary Colors*, the 1992 fictionalized account of Bill Clinton's quest for the American presidency. After repeated denials, Klein admitted writing the controversial insider's account, leading to unprecedented media interest in content analysis. Authorship is determined by examining the prior

works of suspected authors (James Madison, in the case of the *Federalist Papers*, or Clinton's close collaborators in the case of *Primary Colors*) and correlating their frequency of key terms (nouns or function words) with that of the target text.

One of the most remarkable applications of content analysis to political science was undertaken as part of the Manifesto Research Group and the Comparative Manifestoes Project, which estimated policy preferences from the manifestos of a wide range of left-wing and right-wing political parties in more than 50 countries in Central and Eastern Europe, Western Europe, North America, and Asia over the 1944–1989 and 1990–2003 periods. Election programs were taken as indicators of the parties' policy emphasis and policy positions at a certain point in time, and were subjected to content analysis. The analysis ascertained party preferences with respect to foreign relations (anti-imperialism, military, peace, and European integration), freedom and democracy (respect for freedom, and constitutionalism), political system (decentralization, political corruption, and political authority), economy (planning, free enterprise, corporatism, and protectionism), welfare and quality of life (social justice, culture, education, and environmentalism), the fabric of society (traditional morality, law and order, multiculturalism, social harmony), and social groups (labor, farmers, underprivileged). The best-known research resulting from these projects was published by Ian Budge and Hans-Dieter Klingemann in 2001 and by Klingemann and Andrea Volkens in 2006.

While the database generated by the Manifesto Research Group and the Comparative Manifestoes Project is recognized as the most comprehensive and most extensively validated set of policy estimates enabling comparisons over time and space, critics have pointed out that the scheme used to code the political manifestos cannot be changed without jeopardizing its ability to enable meaningful comparative research. Thus, the shortcomings of the coding scheme, most notably its overlapping and missing categories, cannot be adequately addressed without recoding all manifestos all over again, a time-consuming endeavor that many researchers believe would be useless since, by the time the recoding is completed, the new coding scheme would itself be outdated.

### Other Uses

An exemplar of content analysis in psychiatry is James Rogers, Jamie Bromley, Christopher McNally, and David Lester's study of suicide notes that tested the motivational component of the existential–constructivist model of suicide. The content analysis of a sample of 40 suicide notes generally supported the four theoretical categories of somatic, relational (social), spiritual, and psychological motivations outlined by the literature. Psychological motivations were found to be the most prevalent, followed by relational, spiritual, and somatic concerns. Notes of completed suicides included more relational motivations than did those of suicide attempters. Older note writers showed more psychological and fewer spiritual motivations than did younger writers. Based on the study, the authors concluded that the existential–constructivist model of suicide was robust and parsimonious, but at the same time they recommended its revision to provide a stronger meaning-based understanding of suicidal behavior.

In business and management, Richard D'Aveni and Ian MacMillan used content analysis to examine the focus of attention of top managers in companies that are surviving or failing bankruptcy. By examining the letters sent to shareholders by senior managers of 57 bankrupt firms and 57 surviving firms, researchers found out that under normal circumstances managers pay equal attention to the internal and external environment. In times of crisis, managers of surviving firms pay more attention to the critical aspects of their external environment and their firms' output, while those of failing firms focus on the internal environment and their firms' input.

Sociologists David Schweingruber and Ronald Wohlstein used content analysis to examine myths about crowds in introductory sociology textbooks. The authors examined the paragraphs on crowds included in 20 introductory sociology textbooks, coding them for the presence of seven crowd myths, claims about crowds that have no empirical support and have been rejected by scholars in the field. After discovering that the number of myths per book ranged from five to one, Schweingruber and Wohlstein made important suggestions for rewriting these chapters and for improving the book reviewing process.

### Critical Summary

Content analysis is particularly useful for case study research when more sophisticated tools of analysis cannot be employed because they are more expensive or because their use is restricted by a number of ethical dilemmas. By using quantitative and qualitative interpretive analysis, the examination of available records of communication can allow researchers to gain a great deal of knowledge about individuals, groups, organizations, and institutions, provided that their examination is sensitive to both the context and the purpose of the communication.

## CONTENTIOUS ISSUES IN CASE STUDY RESEARCH

---

Generally speaking, a case study may be considered contentious if (a) there is no agreement among the actors and/or researchers as to “what went on” or “what is going on”; or (b) there is limited access to and/or knowledge of the phenomenon under study, either because such access or knowledge has been considered taboo or because questioning the decisions made in relation to the phenomenon has the potential to affect the real-world interests of dominant players. A contentious case involves situations that are unclear or puzzling, where decisions were not, or are not, easy. In general, contentious case studies concern gray or murky areas at any stage of the process of preparing the case, from research to publishing.

### Conceptual Overview and Discussion

Case study research has the potential to raise contentious issues at any stage, from the selection of the phenomenon to be examined (contentious topic), to gaining access to a research site (contentious field site), conducting field research (contentious research process), gaining agreement on data collected, providing feedback to participants, or publishing the study (contentious case research as opposed to publishing more mainstream research).

Research on a contested domain or phenomenon requires an awareness and appreciation of and respect for different voices and interpretations. Rather than imposing an artificial convergence of incompatible views or positions, the researcher should assume and acknowledge that there is no consensus. A contentious topic may be formulated as a paradox, a contradiction, or a dilemma. The starting question is empirical, open-ended, and descriptive, most often based on observation of current events, facts, and trends. The case may focus

on a process (how things have unfolded over time), the construction of a causal system of explanations based on identified independent variables [ $Y = f(X_1; X_2; X_3 \dots)$ ], or a comparative study of the behavior of individuals, groups or societies across two or more phenomena. The design and the methodology of a case study on a contentious topic may be likened to detective work; the researcher follows various pathways and allows the tension between various hypotheses to exist. He or she also pays attention to what have traditionally been undervalued data: seemingly insignificant details in the case, as well as his or her own personal, emotional, cognitive, and relational limitations.

Contentious case studies are a form of process research; Karl Weick encouraged researchers to use verbs in their gerund form (“—ing”) to stimulate process thinking. Analysis of contentious issues relies on the search for new patterns in previously undervalued or seemingly irrelevant or meaningless data. Working in a team in a climate of open debate contributes to the quality of process research on contentious cases.

Publishing contentious cases or case research that has been contentious during the research process may be difficult, for several reasons. Journal editors who hesitate to publish qualitative articles may be reluctant to accept the additional risk of running articles that are both qualitative and contentious. In addition, current journal guidelines do not generally allow for a full description of the efforts required to access, research, and obtain clearances for the content of a contentious case study; in most cases, it is difficult to publish a rigorously detailed description of the methods used in contentious case research beyond brief, formal explanations.

### Application

Examples of contentious issues in business ethics include conflicting values, such as corporate versus organizational values; conflicting analysis of different and discordant voices from diverse stakeholders; the interplay between different levels of analysis and individual and collective action; unresolved conflicts regarding the interests of one group over other groups; or issues related to different time spans (a good decision at one moment in time may be detrimental in the long run).

Contentious case study research is useful for two purposes in two contexts: (1) for the advancement of research, mainly in academic research settings; and (2) for teaching in fields that use problem-based case methods, such as management, law, and medicine.

Case study research can be conducted using primary sources (interviews) or secondary sources (data gathered by other researchers or from archives and publically available documents). Examples (a) in Business Administration include Karl Weick's research on the Mann Gulch disaster, or the classical Cuban missile crisis in which Graham Allison proposed three explanations for the decision-making process the Kennedy administration adopted to confront the Cuban crisis; and (b) in business education include the Dark Side of Business Case Competition with the Critical Management Studies interest group and the Management Education division at the Academy of Management.

### Critical Summary

Contentious issues can arise at any stage of designing, conducting, and publishing case research. Potential advances in research include highlighting a wider range of new and different interpretations, and shedding new light on a phenomenon leading to original conclusions. High-quality case studies on contentious issues require researchers to think strategically about all these stages and dimensions. A specifically challenging situation happens when all the research has been successfully conducted but the challenge of publishing is too high. Working on contentious cases is difficult, but offers a very rewarding way of gaining firsthand experience on critical contexts.

## CONTEXTUALIZATION

---

Case studies are often contrasted with survey research on the basis that surveys abstract specific social phenomena from their wider social contexts, whereas case studies seek to understand specific social processes in a contextualized way, as parts of a wider configuration of social relations. This contrast may be unfair to some survey research, but the argument that detailed case studies place a premium on contextualization captures a central feature of case study research design.

This imperative of contextualization in case study research has several different aspects that involve both internal and external contextualization. Internal contextualization locates any specific aspect of the case in the context of the overall configuration of social relations and processes characterizing that case. External contextualization locates the case as a whole in the wider social context in which it operates. The implications of addressing context in case study research can be explored by clarifying the distinctive features of each of these modes of contextualization and the different ways in which they are pursued in case study research and analysis.

### Conceptual Overview and Application

#### *Internal Contextualization*

Internal contextualization highlights the holistic features of case study research, addressing the interrelationships between different aspects of the case and analyzing the significance of specific events, narratives, and processes in relation to this

wider configuration. Thus a case study of a workplace may locate the day-to-day survival strategies of workers in relation to specific management policy repertoires and their implementation by varied technical and supervisory specialists, and in relation to tensions and alliances between different categories of workers with distinct occupational, gender, or generational experiences. This is an agenda pursued in exemplary fashion by Jean-Pierre Durand and Nicolas Hatzfeld in their study of life on the line at Peugeot.

This concern for internal contextualization underwrites the importance of both ethnography and mixed methods of research in the conduct of case studies. Ethnographic research is characterized by attention to the activities of participants in real-life settings and is thus marked by the explicit contextualization of activity and interaction within its immediate social context. Meanwhile a combination of methods, such as participant observation, key informant interviews, surveys, and documentary research, affords multiple bearings on the configuration of social processes and social relations under investigation. Case studies vary in the mixtures of methods they utilize, and the scope of each study is also influenced by its analytical focus and the research resources available. Nevertheless, a good case study research design must utilize a set of research methods that will be able to satisfy this key requirement of effective internal contextualization.

In pursuing such internal contextualization, a central concern of case study research is for the researcher(s) to be open-minded in exploring the salience of different aspects of the social organization of their case for understanding and explaining focal features of that case. Another imperative is to recognize that this internal contextualization is necessarily selective rather than exhaustive, even in the most detailed of case studies. This relationship between open-mindedness and selectivity in pursuing the holistic and contextualizing agenda of case study research presents a persistent challenge, and different traditions of case study research respond to this challenge in different ways. Thus internal contextualization may be pursued differently by postpositivists, interpretative sociologists, critical realists, or postmodernists.

One possibility, highlighted by postmodernists, is to emphasize the coexistence of a plurality of

potential accounts of any given case setting, and to highlight the ways in which a specific authorial voice underwrites any particular story of the case. An important implication of this approach is that the substantive contextualization of phenomena within the case study should be integrated with an authorial contextualization, reflecting upon the ways in which the researcher's presence inflects the processes of field work and writing, as in Dorinne Kondo's reflexive discussion of power, gender, and discourses of identity in a Japanese workplace.

A rather different approach, advocated by critical realists, among others, is to emphasize the theoretically driven character of case study research and analysis, and the ways in which the theoretical agenda of the researcher guides the logic of selectivity. Here the substantive contextualization of features of the case study is integrated with a theoretical contextualization, reflecting on the ways in which theorizing informs decisions about the design, conduct, and analysis of the case study. While these different metatheories give priority to distinctive forms of contextualization, it also remains possible for authorial contextualization and theoretical contextualization to be combined, an argument advanced by Michael Burawoy in his discussion of the different ways in which the distinctive findings of case study revisits can be understood.

### *External Contextualization*

The other face of case study contextualization involves the external context, the wider setting within which the case itself is embedded. This distinction between internal and external contexts requires a conception of the boundedness of the case being studied, though drawing such boundaries between case and context remains difficult.

Nevertheless, the very conceptualization of a case to be studied implies an analytical and methodological boundedness, which can be thought of in terms of a contrast between the detailed investigation of structures, relations, and processes within the case and a more summary accounting of features outside the scope of such detailed investigation while remaining pertinent to developments within the case.

What counts as salient features of the external context of any specific case study may be suggested

both by the theoretical framework within which the research is conducted and by the process of empirical investigation itself. Such considerations may lead researchers conducting a case study of a school, for example, to attend to features of local and national state policy, the neighborhood, home backgrounds from which pupils are drawn, and/or the roles of teachers' unions and professional associations. The purpose of mapping the external context of any given case study, then, is to situate the case within a wider set of social relations. Such contextualization may operate at a wide variety of scales, from characterizing key features of the global and regional institutions and processes that surround and impinge upon a study of a specific nation or state to mapping features of the immediate institutional context surrounding the intensive study of interpersonal relations in such settings as a household.

The methodological implications of this contrast between internal and external contextualization are strongly formulated in Michael Burawoy's discussion of the "extended case study method." He suggests that, from the vantage point of any given set of case study researchers, these wider features of the external context are necessarily reified as structural conditions surrounding the case. At the same time, the social processes sustaining such external contextual features remain open to detailed study by other researchers. Again, the precise ways in which such features are conceptualized will depend upon the metatheoretical and theoretical approaches of different researchers, and the ways in which these interplay with empirical findings.

### *Ethical Issues*

The scope and character of external contextualization will vary between case studies but should allow the researcher to explicate the salience of wider conditions that impinge upon the specific case and readers to locate the case study in relation to others in similar or different external contexts. However, the external contextualization of case studies also poses important ethical issues. The clear and detailed specification of key features of the external context of a case study, whether of an enterprise, hospital, street gang, or social movement, may jeopardize efforts to

conceal the identity of the case and potentially undermine the anonymity of research subjects. Often researchers respond by limiting the specification of the external context, both to honor promises of anonymity to informants and to protect research subjects more generally from foreseeable harm. This is often ethically crucial, but it should also be recognized that it comes at the cost of attenuating the capacity of researchers to present, and readers to understand, the case in its wider context. This has implications for critical scholarly evaluations of such case studies, as it may limit the scope of revisits, reappraisals, and comparisons with other cases.

### **Critical Summary**

A widely recognized virtue of case study research is that it places specific social processes within their wider contexts, rather than decontextualizing them. This involves both internal contextualization within the case and external contextualization within the wider setting, and it may also be accompanied by authorial and theoretical contextualization.

## CONTRADICTION

---

There are three main ways that we can look at contradiction in the context of case study research. The first is the conventional usage in logic and in science that a contradiction is a logical incompatibility between two or more propositions. Aristotle's law of noncontradiction states, "One cannot say of something that it is and that it is not in the same respect and at the same time." The second usage, especially common in social research, is the axiom that people find perceived contradictions in their lives uncomfortable, and will do their best to resolve them. Finally, a recent trend sees contradiction as inevitable, allowing us to see and explore the inherently mutable nature of both human experience and our understanding of that experience.

### Conceptual Overview and Discussion

For many years, case study research derived its understanding and use of contradiction from the positivist models of science. Something cannot be "true" and at the same time "not true." At a theoretical level, a contradiction arises when two ideas are mutually impossible. Writers in the Marxist tradition, which was built on the Hegelian ideas of thesis, antithesis, and synthesis, argued that contradictions could not exist in reality because reality, once you have established the truth of the matter, does not contradict itself. Only our evaluations of reality can contradict each other. Marxist theorists argued that the job of theorists was to understand the "true" situation and analyze it so that the potentially revolutionary class could see the contradictory situation that surrounded it and move to resolve it. This is a version of the positivist understanding of absolute truth, that is, there is one reality and one truth and it is the work of the researcher to discover that reality.

Many case study researchers have worked with the assumption that the elements of their case must be consistent with each other. If one element of the case appears to contradict the evidence of another, then the researcher sees it as his or her obligation to find out which one is "true." These contradictions, which must be hunted down and either

eliminated or explained, can be between cases or within cases. If it is a multiple or comparative case study, then the researcher must distinguish between difference and contradiction. For example, a study of immigrant adaptation might find that migrants have different experiences, which can be accounted for in differences in the social, economic, or cultural context of both the sending and receiving nation. If, however, the study shows that ethnic similarity is correlated with speed of assimilation, but then finds that ethnically similar women have a much harder time than ethnically dissimilar women, the researcher must explore this apparent contradiction. The contradiction thus becomes the focus for continuing analysis.

Researchers tend to find contradiction within a case much more troubling, especially within a case of one person. If the subject of the study says one thing at one point, and then what appears to be the opposite at another, the researcher has either been inclined to dismiss one statement as "not true" based on his or her understanding of the context or has noted that the subject holds contradictory views and tries to account for those differences, again, according to context. However, long before the "postmodern turn" in sociology, some researchers, especially those involved with working across classes or ethnic groups, noted that "consistency" and "rationality" were not general imperatives but associated with middle-class white educated strata. What was called "hegemonic ideology" in the 1970s (associated with a Gramscian perspective) and is now more often referred to a "dominant discourse" (associated primarily with Foucault's work) had different impacts at different levels of society. Marxist scholars, such as Braverman and Beynon, pointed to the "contradictions" between the version of capital-labor relations as put forward by the management and the media, and the "working-class consciousness" based on workers' experience.

For postmodern scholars who challenge the whole apparatus of the metanarratives of the enlightenment, including the claims of rationality and consistency, previous understanding of contradiction as a puzzle is meaningless in a world now conceived of as transient, permeable, unknowable except in the most partial and fragmentary ways. Some scholars, especially feminist scholars, have looked at standpoint theory as a way of

examining apparent contradictions in both experience and interpretation as wholly rational responses to a multifaceted world.

### Application

Contradiction does not appear as a research tool, or even as an entry in the index of most methodology texts. Yet it is an important part of the background assumptions of all case study researchers.

Mao Zedong provides an exemplar of a rigid application of the Hegelian concept in his essay, "On Contradiction." First describing the philosophical law of contradiction, he lays out the political implications. Capitalism as a social system is inherently contradictory because of the conflicting and mutually exclusive collective goals of the two primary classes, he contends. The differences between the classes are so contradictory that there is no mutually acceptable resolution, which forms the basis for the argument for revolutionary change.

While contradiction is rarely explicitly presented as either a problem or a solution in case studies, we can see how it pushes researchers to new levels of analysis. For example, Beynon's 1970s case study of a Ford Motor plant, and especially of one union leader within it, provides careful explorations of contradictions between what Moss observed in his daily life as a worker and how it was presented to him by management. Beynon's argument is based in the inherent intelligence and ability to see such disjunctures and to develop an alternative analysis that better fits the facts as the worker sees them. This kind of approach insists that there is an underlying rationality to the world we live in, although it may be hidden by dominant social structures and accounts of it.

This differs from the many studies that use instances of apparently contradictory statements of fact or views within the same case to explore further for the reasons. A good example of how this can work comes in Wendy Hollway and Tony Jefferson's study of fear of crime. Their analysis rests on the disjuncture, or contradiction, between the degree and kind of fear of crime that people hold and the objective assessment of the level of actual danger from crime. Among the observations that they make are that the same words cannot be presumed to mean the same things to everyone. As

they point out, the phrase "alone in the dark in a public space" might suggest mugging to older people, sexual assault to women, or an opportunity to fight to young men. They also argue that the traditional sociological assumption of a socially constructed, rational, information processing subject cannot explain the discrepancies that are found in fear-risk research. For this they developed the concept of the "defended" subject based on Freud's notion of "splitting." This means that subjects so "defended" can hold entirely contradictory ideas in their heads at the same time, each with its own validity.

Some postmodern and poststructuralist writers appear to discount contradiction as simply part of the power structures of society that construct us, as subjects, discursively. In much of Foucault's writing, for example, the individual subject effectively disappears as a conscious and independent agent of his or her own life. However, researchers, especially those working in the standpoint tradition, such as Dorothy Smith, have been able to use new thinking to provide far more complex accounts of how disjunctures (i.e., contradictions) between experience and "relations of power" can reveal how people outside those relations, for example single mothers, can construct themselves as knowers and actors.

### Critical Summary

This entry is unusual in that "contradiction" is not often discussed openly in methodology texts or even in the analysis of case studies. Yet it is deeply sown into the background assumptions of researchers. This entry identifies a continuum of ways in which contradiction has been treated in research, ranging from the rigid philosophical interpretation that only one thing can be true at a time, through sociological uses of instances of contradiction as an opportunity to explore a subject's ideas in more depth, but with the assumption that there is an inherent strain toward consistency, to a postmodern approach, which treats contradiction as illustrating the complex and transient nature of what we take to be reality.

## CONTRIBUTION, THEORETICAL

---

In contrast to quantitative research, which aims to generate numerical conclusions based on statistically significant data, a crucial contribution of case studies is the affirmation or development of theory, which can then be generalized or transferred to other settings.

### Conceptual Overview and Discussion

The term *theory* does not have a fixed, universal meaning. Reflecting the competing research paradigms, the word evokes various meanings: the term theory might suggest a determining law, or system of laws, as in the natural sciences, or a construct or set of constructs for ordering and understanding phenomena. Irrespective of the different principles informing the term, theory usually has a central role in case study research. In all but descriptive case studies, the fundamental purpose concerns theory: Case studies either test a particular theory, develop theory, or both. It has been argued that developing theory inevitably involves an element of testing and therefore the two are interlinked. It is by means of this process that a theoretical contribution might be made.

Research projects usually begin with a review of the relevant literature. It is by means of the literature that the researcher will engage with the existing theoretical explanation of the topic in question. For example, if the topic is the incidence of teenage pregnancy, then the range of theories explaining the occurrence of this phenomenon might be ascertained and evaluated. With the exploration of the current strengths and limitations of explanations, the theoretical approach to be tested or developed can be identified. The theory or construct to be

tested or developed will inform the choice of case or cases to be studied, the data to be gathered, the methods by which the data will be gathered, as well as the way in which the data will be analyzed. The project will conclude by discussing the original research question in light of the theory and the empirical evidence gathered.

During the progress of the project, the researcher applies a process of deductive and inductive reasoning. Although often thought of as separate, it has been argued that in case study research, the two processes are blurred and mutually beneficial. Similarly, it has been argued that theory testing and theory development are inevitably associated, and that the interplay of both is implicated. The term *retroduction* has been coined as a means of describing this interplay. Retroduction is therefore the circular process by which the researcher tests his or her theoretical ideas against the emerging data, reframes the ideas, and retests until the conclusions reached are deemed trustworthy. Multiple cases might improve claims to trustworthiness in that the research can be replicated. The replication may facilitate confirmation of the emergent theory, but if not, the theory itself will be redeveloped to take account of the new data. The process of replication may continue as long as is necessary and/or feasible.

The conclusions of multiple cases or even a single case study are generalizable, or at least transferable to a similar context, providing that the research process is trustworthy (measures of trustworthiness depend upon the paradigm in which the research has been located). Two examples of the way in which case study research has contributed to theory are provided below.

### Application

In the 1990s, Wendy Hollway and Tony Jefferson became dissatisfied with the level of knowledge on the fear of crime in the United Kingdom. Knowledge that had predominantly been produced by large surveys measured the level of fear in specific populations (such as men or women) without examining or theorizing what was meant by the fear of crime for specific individuals, or by accounting for the difference in levels of fear between individuals who shared similar social circumstances. For Hollway and Jefferson, the knowledge base was

weak because most previous research had assumed individuals behaved in accordance with the principles of cognitive psychology or were wholly determined by their social environment. Furthermore, survey-based methodologies had not facilitated an understanding of the individuals' lived experience.

Following the literature, Hollway and Jefferson tentatively proposed an alternative theory that challenged the idea that fear of crime resulted from each individual's rational assessment of risk. This theory relied on a different understanding of the human subject: a psychosocial understanding that took into account unconscious processes concerning anxiety. Hollway and Jefferson set about testing their ideas and developing their theory by means of interpretive research that involved the analysis of interviews with individuals or "cases."

Hollway and Jefferson recruited 37 individuals who were different in age, sex, and residential location—that is, they lived in either a high or low crime area. These characteristics informed their recruitment (or selection of cases) as the existing literature identified them as significant. Each individual was interviewed twice, in accordance with the principles of biographical narrative technique. While each respondent's biographical account was interpreted as an individual case study, a comparative analysis was also undertaken.

Hollway and Jefferson were able to show, by means of their empirical evidence, that fear of crime might have different meanings for different people, irrespective of their social characteristics or rational risk of becoming a crime victim. Further, they were able to offer a theoretical explanation of why this was so. In consequence, by testing and developing their theoretical ideas by means of case studies, these researchers have made a rich theoretical contribution to the already established body of knowledge on the fear of crime.

Like Hollway and Jefferson, M. N. Ravishankar and Shan L. Pan have also undertaken interpretive case study research. Rather than undertake a comparison of multiple cases, however, Ravishankar and Pan have examined the single case of India Inc., a global business organization selling a range of services, but most specifically information technology (IT) solutions. Over recent years India Inc. has achieved success and rapidly expanded the number of its employees. It has a complex organizational

structure that involves not only the central structure, which is based in India, but also India Business Units (IBUs). IBUs are decentralized structures staffed with India Inc. employees (outsourced vendors), but located within organizations of their long-term customers.

To improve its performance, the company has invested in the development of a knowledge management (KM) strategy. This strategy is multifaceted, but most important is a portal that enables the sharing of knowledge and expertise, and in which all staff members are expected to participate. This portal has been successful in many respects, but staff members based in IBUs are less likely to comply with the expectation to participate in knowledge sharing. It is to this problem that researchers Ravishankar and Pan turned their attention.

The implementation of the strategy on knowledge management was explored in the light of the distinctive organizational structure. Literature on organizational identity and organizational identification was explored and the case study was designed to answer two research questions: First, how do dual organizational identifications influence compliance with an organizational KM initiative, and second, how are dual organizational identifications managed in a context of organizational KM initiatives? Multiple sources of qualitative data were drawn upon and the resulting materials interpreted by means of an iterative process: Data were read and reread in the light of the pertinent theoretical concepts drawn from the literature.

The case study conducted by Ravishankar and Pan contributes to knowledge in the fields of knowledge management research, business strategy, and management practice. In terms of its main theoretical focus, it offers empirical insights that contribute to the development of theory on organizational identity and organizational identification. According to the authors, as the research was conducted in one particular industry, the theory may be transferred only to a similar setting. For the theory to be widely generalizable, replication of the project in a range of industrial settings would be required.

### Critical Summary

The potential to make theoretical contributions is a particular strength of case study research. In a

new and unexplored area, contributions can be original. In established areas, contributions are more likely to be incremental developments of the work of previous theorists: New empirical evidence from case study research can provide theoretical insights that can confirm or challenge existing theory. In this way theoretical contributions, which have to be appreciated in terms of the competing research paradigms, develop the knowledge base of a range of disciplines.

## CONVERSATION ANALYSIS

---

Conversation analysis is the study of talk-in-interaction. It is a methodological approach that grew out of phenomenology and ethnomethodology and is concerned with uncovering the rules and structures of everyday, mundane social actions as captured through verbal (and nonverbal) interactions. Conversation analysis takes as its starting point that all interactions are meaningful to those

who produce them and that there is an underlying pattern of orderliness to even the most routine interactions.

### Conceptual Overview and Discussion

Conversation analysis views social actions as ongoing practical accomplishments worthy of in-depth examination. At the heart of these social actions is order/organization/orderliness that can be discovered, described, and analyzed to produce formal terms that capture the underlying order. George Psathas discusses seven basic assumptions of conversation analysis, reinterpreted here as four assumptions.

First, order is *produced* by those who engage in social action. Ordered patterns of interaction are determined by the individuals who engage in social action; order is not the result of the researcher's preformed theoretical concepts. Conversation analysis is always an exploratory process and it requires the researcher to approach each interaction (no matter how mundane or brief) open to unique patterns of orderliness.

Second, order is both *context sensitive* and *context free*. It is context sensitive in that each interaction is subject to its own order, that is, patterns of order do not necessarily transfer across situations. At the same time, however, order *can* be repeatable and recurrent across situations. Order is context free in that the particularities of the individuals involved (e.g., personal histories, gender, occupation, type of social action) do not determine the underlying rules and structures of the orderliness. Ethnography is not required to uncover the orderliness of talk-in-interaction. It is important to note that some conversation analysis researchers argue that ethnography is an important complement to their work.

Third, conversation analysis is grounded in description. It is the task of the researcher to discover, describe, and analyze the produced orderliness of talk-in-interaction. Once the rules and structures of social action are determined, formal terms can be employed to capture the ordered patterns of interaction.

Fourth, conversation analysis is not concerned with generalizability. Generalizability and the frequency and scope of social interactions are second to the discovery, description, and analysis of the structures through which order is produced.

Henry Sacks is considered the founder of conversation analysis. Dalvir Samra-Fredericks and Francesca Bargiela-Chiappini note that Sacks's early research with Harold Garfinkel, as well as the research of Emanuel Schegloff, Gail Jefferson, and Anita Pomerantz form the groundwork for the development of the field, beginning in the 1960s and 1970s. George Psathas argues that Erving Goffman's work on the study of interaction in everyday situations also played a critical role in creating space for the development of conversation analysis.

It was through Sacks's employment and case study research at the Suicide Research Center in Los Angeles that conversation analysis as a methodological approach was developed. Sacks began to audiotape telephone calls to the Center to examine the interactional interchanges between Center employees and callers. The recorded tapes allowed him to review the talk-in-interactions over and over to uncover the orderliness of the interactions. Recording talk-in-interaction is now integral to the research design of conversation analysis.

Sacks concluded that initial exchanges between employees and callers were symmetrical in nature and that there was a recurrent aspect of opening sequences. He coined these sequences "units." He noted that these units appeared to occur in turns of two; the first turn was produced by speaker one and the second turn was produced by the second speaker; the context of the first turn of the unit was relevant to the context of the second turn of the unit; and the second turn was related to the context of the first turn of the unit. As a result of this research, Sacks revealed that the seemingly mundane of everyday life was subject to formal description and structures. Talk-in-interaction was comprised of methodical utterances. Later research focused upon uncovering the complexity of turn taking of talk-in-interaction. Sacks's research, and that of the other founders of conversation analysis, revealed that at the heart of everyday social action, sequential structures of action could be discovered and that these units of action were truly interactional in nature because they involved more than one person.

Order is assumed in conversation analysis methodology and patterns of orderliness are understood to be dynamic and processual in nature. The researcher's task is to discover, describe, and

analyze the orderliness of interaction. The researcher does not usually set out with a predefined focus of discovery and already conceived theoretical categories. Conversation analysis is exploratory in nature. Psathas notes that the early stages of such research are characterized as "unmotivated looking." Data should be naturally occurring and not produced for the purposes of the research study. As noted in Sacks's early research, recording of data (audio or video) is critical to conversation analysis research so that interactions can be replayed and transcribed. The recording of data also facilitates the collection of a broad scope of interactions, to be narrowed later in the transcription process.

In case study research (e.g., a specific organization, occupational group, ethnicity), it is common that the scope of interactions collected will be varied and the number of interactions large. The transcription process is not about turning the spoken word into text so that it can be analyzed into more meaningful concepts. The transcription process encompasses the process of discovery, description, and analysis to uncover the rules and structures of ordered patterns of interaction. The transcription process aims to preserve the authentic "talk" of the interaction, rather than drawing out underlying meanings of the talk-in-interaction (e.g., [ring] 1.A: h'lo:~? 2.C:hHi:, 3.A: Hi:~?). Transcribing interactions requires the use of a system of symbolic notations. Gail Jefferson's transcription symbols are commonly used as a guide through the transcription process (e.g., ? = rising intonation, *underlining* or *italics* = emphasis).

Conversation analysis requires researchers to include transcripts of data in their written forms of the research so that others can examine and interpret the description and analysis process directly. Generalizability is not the goal of the conversation analysis researcher. An instance of something is an occurrence, and the frequency of the occurrence is not important in uncovering the order of that occurrence. At the same time, once the unit is discovered, the researcher may examine additional material to find further instances and develop a collection of instances. Psathas notes that a collection of instances may form rich discoveries revealing that the original unit is more complex than first noted or that the second instance is different from the first.

Intrinsic case study research aligns particularly well with conversation analysis methodology. The

intrinsic case is often exploratory in nature, and the researcher is guided by interest in the case itself, rather than extending theory or generalizing across cases. In this way, since the intrinsic case study researcher does not start with a preformed theoretical lens, conversation analysis can facilitate the uncovering of ordered patterns of interaction unique to the case under study.

### Application

Marjan Huisman presents an interesting application of conversation analysis that draws upon case study research from four Dutch organizations. She sets out to discover the rules and structures of talk-in-interaction that characterize decision making. She views decision making as an emergent, incremental activity in which members move forward step by step toward the decision. A decision is defined as a “commitment to future action.” Adopting a conversation analysis approach allows her to identify patterns of interactions and uncover the “structures” of how individuals create meaning in decision making.

The data for the research come from two studies involving four different Dutch organizations. The data from the first study include 12 management meetings videotaped at three different organizational settings: a senior management team of an information and communications technology company, a management team of a service department in a university hospital, and a board of directors of a higher professional education institution. The data from the second study include an audiotape of one key meeting of teaching staff at a Dutch high school. She supplements the transcriptions with interviews and participant observation. As advocated by conversation analysis, Huisman includes her transcription symbols—for example, [DIM] = untranslatable diminutive, (.) = pause of less than 0.4 seconds, cut o- = word cut off—and the English transcribed episodes as well as the original Dutch transcribed episodes.

In the discussion of her findings, Huisman presents four decision-making episodes to highlight three key conclusions: The past, present, and future play a role in decision making, and decision making is interactional in nature; the specific interactional procedures that contribute to a “decision” will depend on the cultural norms of a group (or

organization); and decision making is subjective in nature, whereby the identity of participants contributes to the specific pattern of interactions that emerge.

In episode one, Huisman highlights how decision making is collaborative and interactional. A decision is not captured in one specific utterance. In order to understand the rules of how the decision is made, an analysis of the whole episode of talk-in-interaction is required. Both verbal and nonverbal talk-in-interaction contribute to the achievement of a future state of affairs. In episode two, Huisman argues that decision making is emergent and that often a decision is not explicated as a “decision”; rather, it just happens through talk-in-interaction. In this second episode, the future state of affairs is negotiated. One speaker proposes, then another speaker rejects, then an alternative is proposed, and then the future state of affairs is confirmed. Not every attempt to arrive at a future state of affairs will result in a decision. A decision-making episode can end without a decision.

Episode three highlights how it can sometimes be unclear whether a decision has been made or not. A lack of clarity of the talk-in-interaction may mean that we will not know from a single episode if a decision has been made. We may have to wait until the future state of affairs happens in order to know if a decision had been made in the studied sequence. Moreover, Huisman also notes that what counts as a decision will be largely dependent upon the norms and patterns of behavior of the particular group or organization under study; that is, decision making is context sensitive.

Finally, in episode four Huisman draws attention to how the speaker’s subjectivity contributes to the procedures of a particular decision. First, the speaker’s interpretation of the past influences how it is told in the present. Therefore, talk-in-interaction is not neutral. Second, the identity of the speaker contributes to the patterns of interactions that are uncovered in talk-in-interaction. Speakers’ roles, goals, and interests will inform the underlying orderliness of the interaction. Third, an utterance may have different meanings for different people, even when they are all present during the same episode, making the talk-in-interaction rather complex to discover, describe, and analyze. Overall, Huisman concludes that decision making

is not only bounded rationally, as argued by Herbert Simon, but also socially and linguistically.

Dalvir Samra-Fredericks employs both conversation analysis and ethnography methodologies in her exploration of how strategy is accomplished through the everyday talk of senior managers. She argues that a focus upon the naturally occurring talk of strategists (in real time) provides a richer understanding of the mechanics of how strategy happens, more so than through an analysis of strategists' reports (e.g., through interviews) of how it happens. It is through talk that strategists establish and negotiate meanings and articulate their perceptions of the organization, its stakeholders, and its competitive positioning. It is also through talk-in-interaction that the possibilities of the organization are made sense of and accomplished. In this piece, Samra-Fredericks focuses upon how one strategist (S1), in interaction with five others, effectively persuades the others of his view of the past and future. Through S1's talk-in-interaction tactics, he effectively sets in motion a series of decisions and specific outcomes.

Samra-Fredericks's data come from a private sector organization in which she had access to managers' talk over time (12 months) and space (e.g., over lunch, in meeting rooms). She also draws upon ethnographic experiences over a 12-month period to contextualize organizational level particularities that she argues ground the episodes of talk that occurred over this extended period of time. The larger story is one of "go for growth" by the six strategists. Two organizational weaknesses, as constructed by S1, are the backdrop for the four strips of interaction that she presents: the expertise gap in information systems and the inability of managers to think strategically.

She selects episodes of interaction that are brief but important turning points in terms of the two weaknesses. The four episodes also effectively illustrate what she discovers as six features of relational-rhetorical skills critical to S1's successful talk-in-interaction: emotion is a tactic of expression; the past is spoken of in routine talk of today and the future; a knowledge of when and how to let go, ignore, or question is critical; knowledge needs to be spoken; mitigation and observation of established norms of human interaction are important; and metaphors are used. She includes a simplified set of transcription symbols

(e.g., [ signals interruption, (.) signals a brief pause, *italics* signal emphasis). Overall, Samra-Fredericks's approach to understanding how strategy happens in real time combined the benefits of conversation analysis and that of ethnography to link micro (e.g., human interaction) and macro (e.g., industry conditions) organizational perspectives.

### Critical Summary

Early criticisms of conversation analysis stemmed from its focus on micro sequences; the discovered structures of patterns of interactions were often isolated to single utterances. The discovered orderliness of the micro disregarded how it informed macro-structures and processes. A study of talk-in-interaction, however, can uncover how individuals, through interaction, produce and reproduce social structures. Conversation analysis's attention to detail demonstrates how organization work is accomplished and how individuals are producing the character of the organization in an ongoing matter.

## CREDIBILITY

---

*Credibility* refers to the extent to which a research account is believable and appropriate, with particular reference to the level of agreement between participants and the researcher. It is one of the important considerations in assessing the extent to which a case study or any other type of research study is trustworthy. Credibility should be considered alongside other criteria for trustworthiness, including objectivity, reliability, validity, plausibility, generalizability, authenticity, and other related notions.

### Conceptual Overview and Discussion

#### *Credibility as a Form of Trustworthiness*

There is considerable divergence in researchers' approaches to defining and assessing trustworthiness and in the strategies they advocate to increase the trustworthiness of their research. The labels *internal validity*, *external validity*, *reliability*, and *objectivity* have established themselves as the standards for trustworthiness in quantitative research. For qualitative research, these terms may not be perceived as relevant or applicable, leading qualitative researchers to (a) redefine the terms in the context of qualitative research; (b) adopt alternative terms that more closely fit qualitative research, usually describing their new terms in relation to the standard terms; or (c) reconceptualize notions of trustworthiness by building arguments about the ways that their reconceptualized approach is more faithful to the underlying philosophy and commitments of their particular form of qualitative research than the standard quantitative concepts and terminology.

The notion of credibility is most often associated with the framework presented by Yvonna Lincoln and Egon Guba. They outlined four key questions that relate to the trustworthiness of research findings and provided divergent sets of terminology for quantitative and qualitative research approaches:

1. Are the findings “true” for the participants and the context? This question refers to “truth value,” which is an issue of internal validity or credibility, that is, the degree to which the researcher appropriately identifies or measures the presence or absence of central constructs or relationships among those constructs.
2. Are the findings applicable in other contexts or with other people? Judgments about applicability are typically discussed under the label external validity, which considers whether the findings can be generalized or transferred to another setting.
3. Would the findings be similar if the research were repeated with the same or similar participants in the same or similar context? This is a question of consistency, which may be considered under the labels reliability or dependability.
4. How much have the researcher's biases and perspectives influenced the findings? This idea of neutrality may be discussed as the elusive concept of objectivity or as the less stringent term, confirmability.

As indicated, the first of these four criteria involves credibility or internal validity. This criterion must be considered in relation to the other notions in order to assess the overall trustworthiness of the research data and the resulting reports.

#### *Credibility, Internal Validity, and Reality*

Credibility and internal validity are two ways of thinking about the extent to which a research account is truthful. Researchers who perceive the existence of an external reality that can be measured or approximated through research data tend to commit themselves to goals of demonstrating that their measurements truly reflect research constructs as they exist in the external world. These researchers tend to adopt the language of internal validity to discuss the resulting truthfulness of their research accounts. For these researchers, there are various theoretical approaches, some with accompanying statistical measures, to assess the match between their research data and some external reality.

In contrast, researchers who perceive reality as a social construction and hence acknowledge the existence of multiple realities, tend to be concerned

with articulating whose reality is captured in the research and to whom the research is believable and appropriate. These researchers may adopt the language of credibility with an understanding that credibility must be assessed from some perspective rather than as an inherent quality of the research. John Creswell and Dana Miller, for example, consider credibility from the perspectives of researchers, research participants, and research consumers (i.e., readers and reviewers of the research).

### *Strategies to Enhance Credibility*

Researchers have identified several important strategies that can help to enhance credibility during data collection, analysis, and reporting. To establish credibility, researchers strive for data saturation. They collect and analyze data on an ongoing basis, continually comparing to see if new ideas, constructs, and themes arise or if the same notions reemerge. Case study research reports include thick description that brings the case to life for readers. Triangulation across multiple sources of data, including possible contradictory sources of data, can reveal convergences, divergences, and discontinuities that are essential to describing the case. Maximum variety sampling can be particularly helpful in uncovering negative evidence.

Research that involves prolonged and persistent field work provides sufficient time and depth of data for researchers to identify key aspects of the case and address potential distortions that might otherwise be introduced in the case. Extended time in the field is also essential to building trust with research participants, thereby increasing the likelihood that they will be open and honest with the researcher, and that they will accept the researcher's interpretations. In some cases, the researcher may become a participant in the community and thus be able to provide an insider's view of the case.

Researchers may work in consultation with other researchers, providing opportunities for comparisons that may uncover convergences, divergences, and discontinuities in the data interpretations. Likewise, some researchers invite participants to collaborate as coresearchers, thereby providing an insider perspective for the research that may be seen as more credible to other participants and readers.

Researchers can adopt a reflexive approach to document how their own biases and perspectives influence data collection and interpretation. Qualitative researchers emphasize the need for full disclosure about how and why they have interpreted data in particular ways. Some researchers focus upon low-inference descriptors, verbatim statements, and nonjudgmental descriptions of the participants and the settings to provide a level of verisimilitude that is convincing to research participants and readers.

Member checking is often seen as central to establishing the credibility of a research account. Consultations with research participants or other members of the community throughout data collection, data analysis, and report writing provide opportunities to assess the level of agreement regarding the accuracy of the data and the researcher's interpretations and accounts drawn from those data.

Credibility is enhanced through opportunities for peers, external consultants, or auditors to review and verify the evidence. The use of mechanical recording devices allows researchers and their assessors to review data resources after leaving the field. Verbatim statements from participants in field notes, in audio or video recordings, and in research reports can be readily connected, especially when the report has specific citations to the database where the evidence can be found. Researchers can also document the steps followed during data analysis and trace the development of final categories or propositions for their research reports. Robert Yin describes the importance of providing a "chain of evidence" for external assessors to link evidence from research records to case reports. Lincoln and Guba discuss this same point using the term *audit trail* for the evidence used in formal credibility assessments by external reviewers.

### **Application**

Mary Rodwell and Katharine Byers provide a detailed credibility assessment for two case studies of decisions regarding child neglect. Rodwell collected extensive data from parents, school personnel, social workers, police officers, attorneys, and judges over a 6-month period. She recorded her research data in field notes and various forms of journals. She established an audit trail through

activity logs and methodological logs that she maintained throughout the research process. She documented the various decision rules, data units, categories, and coding systems that she developed. Five participants provided member checks attesting to the credibility of Rodwell's research from their perspectives.

Rodwell then contracted Byers to conduct an external audit of the trustworthiness and authenticity of the two case studies. Byers reviewed the audit trail provided by the journals, logs, and research documents and prepared a formal assessment in the form of an audit report. As an external auditor, Byers provided her judgment about the credibility of the research, not a final statement about the quality of the research. Positive judgments about the credibility of the research from the perspectives of the five participants who engaged in the member checks and the external auditor (Byers) increase the likelihood that subsequent readers of the research will likewise judge the work as credible.

### Critical Summary

It is important to consider the credibility or believability of any research study. There is a range of strategies that can enhance credibility for case study research. The specific strategies adopted in any particular case study to enhance credibility depend upon the goals of the researcher, the guiding frameworks for the research, and the nature of the case itself. Credibility is a relative judgment taken from a particular perspective, rather than a definitive claim about the case study as a whole.

## CRITICAL DISCOURSE ANALYSIS

---

Critical discourse analysis (CDA) is a theoretical and methodological framework that allows one to examine the constitutive role that discourses play in contemporary society. Its origins lie in applied linguistics, and it has been developed by scholars such as Norman Fairclough, Teun van Dijk, Theo van Leeuwen, and Ruth Wodak. In recent years, it has been applied in various ways across social and human sciences. Foucauldian and other poststructuralist approaches are at times also considered critical discursive analyses, although their epistemological assumptions are somewhat different. While many underscore the differences, there is a linkage between the approaches as, for example, Fairclough's work draws on Michel Foucault's ideas.

Against this background, it is not surprising that one can distinguish several different approaches under the broad umbrella of CDA. For example, Fairclough and Wodak distinguish between French discourse analysis, critical linguistics, social semiotics, sociocultural change and change in discourse, sociocognitive studies, the discourse–historical method, reading analysis, and the Duisburg School as important traditions in CDA. Since the label of CDA is sometimes associated exclusively with Norman Fairclough and colleagues' work, some scholars have suggested that we should move toward using a broader notion of critical discourse studies (CDS) instead of CDA.

### Theoretical and Methodological Basis

What are the general characteristics of CDA? Essential are at least the following four features. First, CDA focuses on the role played by language in the construction of power relationships and reproduction of domination in social and societal life. Of specific concern are usually social problems

and inequalities in the contemporary world. In a sense, CDA attempts to make visible taken-for-granted assumptions that easily pass unnoticed in more traditional analyses. Second, CDA involves an in-built critical stance. Thus, a researcher is not a “neutral observer,” but his or her role is to acknowledge a particular kind of (critical) perspective.

Third, contextuality is a crucial issue in CDA. Consequently, the ability to place specific texts in their contexts is important in CDA. On the one hand, this means taking the social, cultural, and institutional settings seriously. Norman Fairclough, for example, argues that discourses should be analyzed at three levels simultaneously: textual (microlevel textual elements), discursive practices (the production and interpretation of texts), and social practice (the situational and institutional context). On the other hand, the historical dimension is important in CDA. In particular, Ruth Wodak argues for a historico-discursive methodology where specific texts and discourses are placed in their historical context. This kind of analysis should thus link textual representations with social and material practices, which is naturally a demanding task for any scholar. Furthermore, such analysis thus often becomes interdisciplinary. In fact, some CDA scholars argue that the essence of CDA is to combine methods of linguistic analysis with social theories and subject-specific understanding.

Fourth, intertextuality—linkages between different texts—is a key issue in CDA. In brief, one cannot fully understand specific texts or discursive acts without linking them with other texts and discursive acts. Thus, as in other contemporary discursive methodologies, discourses are seen to be constituted by complex webs of texts, and even if CDA often focuses on close analysis of individual texts, these texts should always be placed in their intertextual context. This issue of intertextuality is also related to the broader question of interdiscursivity, that is, how specific discourse and genres are interlinked and constitute particular “orders-of-discourse.” Such orders-of-discourse are then seen as essential parts of power relations and systems of domination in contemporary society.

CDA is open to various kinds of methods. This kind of research demands the ability to make sense of, on the one hand, linkages between specific textual characteristics and particular discourses, and, on the other, linkages between discourses and the

relevant sociocultural practices and historical developments. This means that research of this type usually tends to favor in-depth scrutiny and reflection on specific texts rather than more formal methods of analysis such as content analysis. This is not to say that content analysis or other similar methods are not valuable tools in CDA, but that on their own they are most often insufficient for “digging deep” into the relationships of text, discourse, and sociocultural practice, and to understand the constitutive role that discourses play in society.

What are suitable empirical materials for CDA? In principle, any kind of textual material (documents, speeches, conversations, media texts, etc.) is useful for critical discursive inquiry. In addition, it often makes sense to include visual representations in the analysis, for example, in the form of pictures, symbols, and so forth. Different modes of semiosis may turn out to be important in the critical analysis of discourses in particular contexts.

### Application

CDA can be used in various fields of social science. In fact, Norman Fairclough has emphasized that CDA has been developed to serve interdisciplinary research efforts. Organization and management scholars have been active in adopting these ideas and methods, and applying them in different ways for understanding different phenomena in and around organizations. For example, Nelson Phillips and Cynthia Hardy provide examples of empirical studies where critical discourse analysis has been used to better understand how concepts, objects, and subject positions are constructed in organizations. While there is no specific right way to use CDA in case studies, the formulation of a focused theoretical framework, selection of texts, and the choice of methods of analysis are crucial strategic issues therein.

One illustrative example of CDA is provided by Bob Hodge and Gabriela Coronado, who examined the role of strategy documents from a critical perspective. They focused on the Mexican government’s Plan–Puebla–Panama, which is a historically significant policy document dealing with the southeast region of the country. They analyzed the various discursive and ideological elements of this document, and illustrated how discourse on economic reform involved a “complex” of global

capitalist and nationalist discourses and ideologies that was used to promote the opening up of Mexican markets to MNCs (multinational corporations/companies) based outside of Mexico. Their analysis also showed that the form and vocabulary of the document reproduced corporate rhetoric and thus had a fundamental impact on the discursive and ideological struggles in the Mexican society.

Another example of recent applications of CDA is provided by Eero Vaara and Janne Tienari, who analyzed the discursive legitimation of a shutdown decision by a MNC in Finland. Their theoretical framework was based on Theo van Leeuwen's and Ruth Wodak's work on discursive legitimation strategies. In their analysis, they focused on a "typical" media text dealing with the decision to shut down an industrial unit that had in fact been profitable. Through a close reading of the relatively short text, Vaara and Tienari distinguished and elaborated on discursive strategies such as authorization, rationalization, moralization, and mythopoesis that sought to render the shutdown decision inevitable in the context of globalization. They concluded that such microlevel strategies are concrete means through which controversial actions are legitimated in contemporary society.

The studies by Hodge and Coronado and by Vaara and Tienari demonstrate some basic tenets of CDA. Both are concerned with controversial issues that contain potential social problems and inequalities. In both studies, the authors sought to bring to the fore, and critically scrutinize, taken-for-granted assumptions that easily pass unnoticed. Both studies took care in placing the text(s) studied in context, reflecting on discursive and sociocultural practices around the focal text(s). This included reflections on intertextuality: linking the focal text(s) with other texts and discursive acts.

### Critical Summary

Critical discourse analysis has become increasingly popular across social sciences and humanities because it offers an opportunity to better understand contemporary social problems by targeted linguistic analysis. However, applications of CDA have been frequently criticized for a lack of rigor and detail in the actual linguistic analyses. Moreover, students of CDA have at times been accused of self-serving selections of texts and distorted interpretations.

CDA forces the analyst to take a stand on issues, more so than in conventional analyses. This should not be misinterpreted as a license to produce any kind of critical comment based on one's convictions or general observations. On the contrary, precisely because the critical discourse analyst is usually dealing with complex issues that allow one to express multiple and contradictory points of view, it is necessary to make sure that one's own interpretations are backed up by textual evidence and logical chains of argumentation. Carried out in this way, CDA is useful for case study research in its own right, but it can also be used to complement other research efforts. For example, studying the social construction of specific phenomena may involve combinations of ethnographic methods and critical discourse analysis, as long as the researcher does not attempt to do too much and is aware of the underlying assumptions behind the specific methodologies in question.

## CRITICAL INCIDENT CASE STUDY

---

The critical incident method (sometimes referred to as the critical incident technique) is a methodology used primarily for exploratory research. It is a flexible qualitative or mixed methods technique used for the study of factors, variables, or behaviors that are *critical* to the success or failure of an activity or event and associated outcomes.

### Conceptual Overview and Discussion

While case studies of significant incidents or events have a long history of interest to scholars, the critical incident method as a method was first formalized by Colonel John C. Flanagan during World War II. His analytical efforts were focused on military persons and their work behaviors in order to determine which patterns of behaviors carried out in the conduct of a task were effective or noneffective; that is, those behaviors that were related to, and that were *critical* for, the success or failure of a task. In his first formulation, the critical incident method was described as a set of principles that could be used to study human behavior and its relation to a particular activity such as pilots engaged in the activities necessary to the flying of an airplane, or to a more specific event such as success or failure at properly and safely landing an aircraft. However, over the past five decades the critical incident method or critical incident technique has spread beyond its original behaviorist beginnings; and the method has since been both widely adopted and adapted across many disciplines for use in case-based research.

When used as the primary method for case research, the critical incident method normally has a particular event-based focus. That is, the method is used to investigate or explore particular types of events or incidents—those that researchers perceive to be *critical* in some way. By definition, these critical events are significant, unique, or

unusual in some aspect of interest to the researcher. For example, they may be cases of failure or near failure, or of disaster, calamity, or catastrophe. Alternatively, they could be focused on unusual or significant cases of successful or serendipitous events or outcomes.

Critical incident case studies have the goal of exploring answers to questions such as who was involved in the event, what did these individuals do (or not do!), and how did their actions or inactions contribute to the incident or outcome? While originally developed to study, and consequently propositionally bounded by, the behaviors of persons and their relation to events or outcomes, the scope of critical incident case research has also expanded from its original behaviorally constrained domain. This technique and methodological approach is now being used to study not only persons' behavior(s), but also their cognitions, their emotional state(s), or almost any other individual characteristic of interest. In addition, the approach has moved beyond the individual; the range of antecedents, facilitating factors, or contributing variables to be investigated now include factors at the individual, group, or organizational levels and may also incorporate both internal and external variables of interest.

So useful is this approach to case study that it now is used in industrial and organizational psychology, education, medicine, engineering, human factors design, organizational analysis, and many other fields. Yet despite the enlargement of the domains in which the critical incident method has been used, the primary goal of using this approach to case study generally remains the same as its original purpose: the determination of the causal antecedents of an event and those critical actions or inactions taken by actors or agents that contributed to the event's or outcome's occurrence.

### Application

Unless a specific individual's behavior is the focus of research, given the complexity of the study of modern phenomenon in our world today, it is unlikely that the actions of one and only one individual will be able to provide a sufficiently comprehensive and satisfactory explanation to any research question of interest beyond this level. As a consequence, critical incident methodology

beyond the individual level requires an exacting approach to collecting, organizing, and relating evidence. Almost all events or critical incidents (less those personally witnessed by participant observers) will be post hoc analyses. Therefore, a combination of evidentiary material will normally be used within the case study. For example, interviews, documentation (written, audio, video, etc.), and possibly physical artifacts may all serve as forms of case evidence. Regardless of the form, case evidence will normally need to be gathered from multiple sources and integrated.

This state is highlighted by the work of Charles Perrow, who shows how individual behaviors in conjunction with tightly coupled, human designed systems almost inevitably lead to catastrophic or near catastrophic outcomes. In order to account for, or explain, the type of accidents that may happen in our complex, largely systems-based world, he uses a variety of data from multiple sources, including interviews, technical systems reports, diagnostics, and performance statistics.

Similarly, Karl Weick has also used this approach in his research. In two separate studies, one the death of 13 firefighters in his now-famous Mann Gulch disaster case, and in a second, the Tenerife aircraft disaster, where two large aircraft collided resulting in the deaths of nearly 600 persons. For the Mann Gulch case, Weick used what was, in essence, a critical incident approach to study how the behaviors of individuals and groups are influenced by their individual and group-level sense-making activities and how the effects of these processes can lead to highly negative outcomes. Weick shows how a breakdown in individual role and group sensemaking was a direct causal factor in their deaths. In the Tenerife case, like Perrow's work on technological systems, Weick shows how a combination of individual behaviors, breakdowns in sensemaking, and technological systems led to the collision and subsequent deaths.

While theoretical propositions, relationships, or processes may be postulated as a result of the analysis of case material using this approach, the case researcher must be careful not to offer ecological generalizability. As a function of the nature of the object(s) of study, a critical event or incident, the very specific methodological approach in combination with the unique nature of factors antecedent to these events or incidents means that

critical incident method based cases should be considered only analytically generalizable. That is, the results of the study may provide an analytical or propositional framework within which to analyze other, perhaps similar, events or incidents.

## CRITICAL PEDAGOGY AND DIGITAL TECHNOLOGY

---

Critical pedagogy seeks to create a critical consciousness through a power-minimal discursive educational practice. Digital technology can further empower the learner by allowing the learner to develop the case study discourse directly.

### Conceptual Overview and Discussion

The purpose of this entry is not so much to give an account of critical theory and pedagogy in general, or more precisely, critical pedagogy and the philosophy of technology. Rather, the question lies in how digital technology can advance the agenda of critical pedagogy through its use in case study application. A case is something that is *done*, not simply something prepared and sold. This Socratic

method of teaching uses a situation, specific or general, to provoke critical thinking, or more radically to provoke a reaction against hegemonic practices through a power-minimal discursive situation in order to create counter-hegemonic discursive practices and hopefully a critical consciousness. The pedagogical converse often is presented as the one-way “Sage on the Stage” lecture method, what Freire called the “banking” model of teaching. Before attending to the discussion of how digital technology can revolutionize the case study method consistent with the perspective of critical pedagogical thought, this entry isolates the key constructs and quickly summarizes the critical theorists who brought these ideas into being.

### *Hegemony and Power*

Antonio Gramsci spent 11 years in prison under Mussolini, during which time he wrote 32 notebooks in all and in the process gave us a tangible expression of a Marxian notion of ideological domination called “hegemony.” A hegemonic practice dominates the cultural landscape and tends to legitimize oppression through the social relations of production and the concomitant institutions and ideologies that support them. The dominant system of belief, this mode of understanding, within the popular frame of mind contributes as much to oppression as any physical expression of power, contra Mao Zedong who said that power comes solely from the point of a gun. Hegemony allows for ruling by “consent,” using ideological outlets; people move willingly as it seems to be in their best interest to do so. This notion of false consciousness, however, owes more to Georg Lukacs than Gramsci. Nonetheless, Gramsci’s development of the concept of ideology begins the critique of hegemonic popular culture by advocating counter-hegemonic practices through ideological institutions such as educational practices, work practices, and more.

Gramsci also gives us the notion of the “organic intellectual.” Critique is not the property of academicians alone; rather, a critique of hegemonic practices, and creating the possibility for transformation, can happen in the classroom, and indeed any institution. Gramsci’s view of the organic intellectual is important when the teacher understands that he or she is not the sole bearer of

intellectual critique, particularly those working with adult learners who are actively engaged and leading in these practices. This understanding allows for the dispersal of power in the classroom and maximum engagement. Gramsci understood that the instructor plays a crucial role in getting organic intellectuals to critique dominant hegemonic practices inside the classroom and out. The instructor helps the learner to demystify hegemonic social practices by creating counter-hegemonic practices.

Michel Foucault explored the problem of power and social control through a set of critical studies on social institutions. Foucault wrote about the formation of knowledge, power, and human discourse in the context of specific dominant institutions, for example, asylums, prisons and punishment, medicine, and, late in his life, on the social construction of sexuality.

Foucault gives us the concept of knowledge/power; all knowledge is power; power is dispersed; social institutions build around them a language of practice meant to legitimate their domination. This Orwellian disindividualization automates and distributes power through institutions. However, the individual is capable of action even if ways of “governance” ontologically create an epoch, a worldview, that constrains language, meaning, and choice and as such perpetuates domination.

Further, Foucault speaks of normalization, the totalization, and the process by which society creates the individual, for better or worse, opposing monarchical top-down notions of power. Like Gramsci, Foucault understood that the ideological side of power is diffuse, operating and emerging up from the margins of shifting micromechanisms. And while the normalization process cannot, and sometimes should not, be avoided, it can be critically understood and when needed challenged, even transgressed, looking for the marginal nodes of resistance. It is to the margins of power that critical pedagogy looks.

### *Critical Pedagogy*

The goal of any critical pedagogy is to create a critical consciousness, a desire to help the learner see and understand oppressive social practices, create counter-hegemonic practices, and work toward social change. The attempt to allow learners the opportunity to identify and challenge hegemonic

social practices comes from a place of respect, where the learner as an organic intellectual contributes to the discussion through a power-minimal situation. Fundamental to the notion of critical pedagogy is that the classroom is never politically neutral. Learners and instructors bring with them the ways in which they have been normalized and the understandings they pursued as organic intellectuals. Furthermore, the instructor will always have some level of power, be it evaluative, constitutional, or simply the fact that there is an economic exchange going on. Professors of critical pedagogy must get paid for their services and the student pays them, however distasteful the customer concept may be. So the question becomes not to be power-neutral, but how to become power-minimal.

Critical pedagogy as we knew it in the last half of the 20th century, and as it exists today, starts with the work of Paulo Freire. Freire introduced the notion of the classroom, not dissimilar from Gramsci, as a contested space where the political-neutrality chimera, the *tabula rasa*, is replaced by a dialogic of race, gender, sexuality, religion, disability, and more that must be brought out into the light and discussed. Freire sought to use a power-minimal educational space to create the critical consciousness of the learner such that he or she is prepared to take part in the collective need to challenge hegemony and work toward social justice. Freire and his students pursued an aggressive drive for emancipatory change, a critical analysis of language games in a globalized postcolonial context. But more fundamentally, Freire understood that learners were not empty accounts in which to deposit knowledge, the “banking” concept of education. Learners need to be challenged to think critically, and helped onto the path of social transformation, and the consensus sought in the dialogical classroom will create just that.

One of the most active of Freire’s students, Henry Giroux, influenced by the more postmodern direction of his generation, objected to Freire’s notion that a critical consciousness will naturally emerge from dialogical critical thinking in the classroom moving toward consensus. Seeking consensus is neither possible nor necessary, Giroux maintained. A didactic classroom has the chance of producing critical consciousness; but the search for consensus will not make it so of necessity. Indeed, the lack of consensus deriving from even

the most minimal of power situations is actually a good thing. Fundamentally, Giroux’s studies how a school, as the site of battles for popular culture, affects today’s youth.

In time, Giroux began working cross-disciplinarily in media studies and literary studies, crossing academic borders while calling for a “border politics” that pushes learners to think critically about the possibility of radical democracy though transgressing into each other’s border regions. Giroux fundamentally widens the notion of “schooling” beyond public schools, to include all popular culture, as young people are educated as much by television and the media as by what goes on in the classroom. Understanding youth culture, the intersection of race, gender, and more, teachers need to reinvigorate democratic culture as one part of the cultural space that makes possible the maximum amount of democratic participation for the young, who are the main focus for Giroux.

Of course there are many other critical pedagogists to discuss. Peter McLaren, motivated by an interesting combination of strict Marxist–Leninism and a form of Marxist humanism, pushes issues of globalization and mass media, continuing the notions that the school is only one site of political discourse and that teaching must be informed by an understanding of the larger popular culture in which learners learn to be who they are. Engaging diverse language games, decolonizing, and pushing interchange with indigenous peoples, the critical pedagogical movement goes forward through diversity and dialogue. Practitioners do not give up one ideology to bank in another, as the dialogical process in a power-minimal discursive space is used to give voice to the diverse perspectives available in the classroom. And while it would be enjoyable to diverge into popular culture, particularly with Douglas Kellner, taking his perspective on critical theory and media studies into education, this would draw us off point. As such, we now have enough of an idea of critical theory and critical pedagogy to see how digital technology is likely the most significant opportunity for aggressively pursuing the agenda of critical pedagogy.

### Application

Generally speaking, case study analysis and critical discussions more and more replace the

one-way lecture model as a means of empowering students and generating critical thinking. However, case studies done in print form have two distinct disadvantages. First, in the “real world,” no supervisor ever says that we have a problem and here is all the information you need to solve it. Finding what one needs, research perhaps, or what is often called “information literacy,” is lost in this preset case presentation. Second, and more to the point, in the printed case, the case designer dictates the terms of the discussion by providing most if not all of the information necessary to do the case. By determining the universe of discourse in a preset case, the instructor and case designer have a one-way power relationship with the student. Using digital technology to create and implement case studies addresses both of these concerns. Students research the case digitally while taking the case in the direction that means the most to them as organic intellectuals worthy of respect in their own right, such that developing a critical consciousness and creating counter-hegemonic discursive practices emerges naturally.

In print it is difficult to show the full potential of the critical digital case-based approach. A brief sketch of an example here, coming from an undergraduate course in business ethics, makes the point. Specifically, ask most students, indeed, ask most people you know, and they will say that affirmative action is a thing of the past. With the election of President Obama, racism has been defeated, the glass ceiling broken by Hillary Clinton or Sarah Palin, and we simply do not need any kind of preferential treatment programs, as racism and sexism and other forms of discrimination are things of the past. Declaring victory in the war on hate and oppression, however, may be premature. In order to move toward a critical consciousness on this issue, one has to spin the case in a way that makes learners reflect on their basic assumptions about race, gender, and more, in the context of affirmative action.

This passage is taken from the Web site of the Disabled Veterans Affirmative Action Program (DVAAP) (<http://www.opm.gov/employ/veterans/DVAAP.asp>):

Most departments and agencies in the Federal government are required to have an affirmative

action program for the recruitment, employment, and advancement of disabled veterans. The law requires agencies to develop annual Disabled Veterans Affirmative Action Program (DVAAP) Plans.

The question that can be put to students:

Should disabled veterans get preferential treatment over better qualified candidates who are not disabled veterans? Make sure to contrast DVAAP to programs that involve affirmative action for women or people of color.

At this point it becomes the job of the learner to decide the direction of the case. More information is available online than one can imagine, and it becomes the instructor’s job to tutor students in their research. From cyber libraries like Proquest, EBSCO, JSTOR, and more, learners can access academic journals of all types, for example, the *Journal of Business Ethics*; magazines from *Forbes* to *Mother Jones* are available, along with newspapers like the *Wall Street Journal*; in other words, anything that is not available for free online can be found in cyber libraries.

Beyond these libraries, students can be given a listing of the top *meta-sites* in the field in order to jump start their research. One of the best meta-sites on the subject is the Affirmative Action and Diversity Project, which represents a variety of viewpoints, eschewing simple pro and con, giving opportunities to different voices in the debate on affirmative action:

<http://aad.english.ucsb.edu>

Other meta-sites include

The American Association for Affirmative Action, [www.affirmativeaction.org](http://www.affirmativeaction.org)

HR Guide to the Internet, [www.hr-guide.com](http://www.hr-guide.com), [www.findlaw.com](http://www.findlaw.com)

Such sites will get learners to the latest news, state actions, and current legal cases; links to institutional policy; programs for different businesses institutions; the Bureau of Labor Statistics; Department of Labor sites; the Equal Employment

Opportunity Commission; along with major affirmative action legal decisions, political policies, executive orders, and more.

These meta-sites alone link to more information on affirmative action than preset case studies and textbooks, and this discussion does not include what happens when the learner simply goes to Google or any other search engine. With the world of information available digitally at their fingertips, learners then have the chance to decide which direction to take the argument. In this case, some learners will focus on the “merit” argument; others focus on “compensatory justice” arguments, still others on issues of “reverse discrimination,” and so on. Thus, a learner can take the direction that he or she finds most intriguing. By being allowed to direct the development of the case, the learner comes to see the complexity of the argument and begins to rethink his or her position and begins to create counter-hegemonic discursive practices that move toward a critical consciousness on issues of race, gender, disability, and more.

### Critical Summary

The catch here of course lies in what is known as the “digital divide.” The haves and have nots, poor or rich, urban or rural, developed versus developing country; economic advantage affords differential access to digital technology. And while Doug Kellner cautions against seeing the digital divide as a marketing gimmick and a way for techno-corporate interests to push their products, there is wide agreement that, so long as we stay with an instructor-based model and do not move to a digitized correspondence program as Andrew Feenberg explains, we can work toward building a critical consciousness, a Deweyian commitment to democratic values, and use digital technology to allow the learner to dictate the direction of the case study analysis. Empowering the learner to take the course of his or her greatest interest creates a power shift in the case-based classroom that helps the learner to discover and resist hegemonic practices by creating counter-hegemonic practices and moving, in time, toward a critical consciousness.

## CRITICAL REALISM

---

Critical realism provides a distinctive account of the bases of the natural and social sciences, challenging versions of empiricism and positivism but also offering an alternative to social constructionist and postmodernist accounts of the social. Thus it represents a distinctive approach to the ontological and epistemological underpinnings of social research, rejecting the polarized terms of much debate between these positions. In particular, it combines an ontological insistence on the existence of objective natural and social realities with recognition of the socially constructed and fallible character of scientific knowledge.

Much of the advocacy of critical realism has remained at a high level of abstraction. Philosophers and social theorists have provided generic statements about this approach to analysis and explanation in the social sciences, but have rarely considered the implications for specific styles of social research. Nevertheless, growing numbers of researchers have found the programmatic stance of critical realism attractive because it offers a warrant for existing research approaches that do not conform to either positivist or social constructionist protocols.

Some recent discussions have addressed the implications of critical realism for different approaches to social research. Some commentators have identified specific affinities between critical realism and case study research, but others suggest case studies represent only one among a range of appropriate research designs. There is nevertheless widespread agreement that critical realism does

not simply underwrite existing research designs and forms of analysis, but encourages their reappraisal and refinement in the light of its precepts.

### Conceptual Overview and Discussion

#### *What Is Critical Realism?*

Even among critical realists there are important differences of position. Some are more optimistic and some more pessimistic about the scope for an explanatory social science. Writers also disagree about the character and implications of the critique implied by the term *critical realism*. But it is widely recognized that the work of Roy Bhaskar has been foundational in establishing and developing the implications of this distinctive approach to the philosophy of science.

His early work concentrated on challenging empiricist and positivist accounts of the procedures and discoveries of natural science, though by extension this also challenged such approaches within social science. Key arguments focused on the theory-laden (not theory-determined) character of observation and the inappropriateness of constant conjunction as a criterion for causality. These arguments suggested that the relationship between natural reality and scientific knowledge involved a stratified ontology marked by distinctions between the real, the actual, and the empirical.

While the “real” involves the underlying causal properties and powers of nature, the “actual” involves the particular ways in which these powers are expressed as they are triggered by particular conditions or as causal mechanisms interact. Thus causal powers may not be triggered, so “exist unexercised,” or such powers may be disrupted, thus “exercised unactualized” (or in modified form). Since the outcomes of causal mechanisms may not be registered by observers (i.e., as the “empirical”), they may also be “actualized unperceived.” These arguments frame a distinctive account of scientific experiments as efforts to isolate the operation of particular “causal mechanisms” by controlling the contexts within which they operate. This is coupled with a sharp distinction between the system closure that may be achieved by experimentation and the open systems within which natural mechanisms typically operate.

This represents a distinctive philosophical underpinning for a nonempiricist and nonpositivist account of natural science, and potentially a parallel account of social science. For critical realists, however, a unified view of science is tempered by attention to the particular properties of the realms of reality addressed by specific sciences. Two properties of the social are of particular importance. First, all human actors operate with accounts of the social world they inhabit, introducing a necessarily reflexive character to social science. Second, human capacities for reflexive innovation mean that experimentation as system closure is rarely possible, making the isolation of causal mechanisms more problematical in the social realm. This second feature, especially, leads to debate about the scope and limits of social science.

Critical realists are nevertheless united in two key features of their approach to social science, both arising from their nonempiricist and stratified conception of social reality. First, hermeneutic understanding of the meanings humans attribute to their activities is an essential but not sufficient feature of social science. Second, social structures are characterized by real powers and effects, though these structures are often unobservable. One influential development of these arguments is Margaret Archer's insistence on the duality of structure and agency. Structures of social relations are not merely epiphenomena of social interaction, but have distinctive emergent and enduring properties that will constrain or enable different lines of action, although these properties may then be modified by ensuing individual or collective action.

Similarly, cultural discourses have their own emergent properties, but these must be assessed in terms of their interplay with structures of social relations and lines of reflexive action, rather than becoming the sole focus of analysis. Furthermore, such assessments of the interplay of structures, cultures, and their agential mediation must have ontological depth. They must address the ways in which agency is constrained and enabled by existing structures, which necessarily involves attention to temporality, to the role of precursor conditions and sequences of development.

This involves a distinctive analysis of actors' accounts of their experiences and orientations, as the location of such accounts within a wider complex of causal mechanisms provides the basis for

assessing both their motivational efficacy and their cognitive adequacy. This is one basis for critique within critical realism. Another is the assessment of existing structures in terms of how they constrain or enable the fulfillment of human entitlements or aspirations. Such arguments imply a complex relationship between what is and what ought to be, rather than their stark separation. This often underpins an orientation to possibilities for social transformation, though those critical realists most cautious about the analysis of complex open social systems may be hesitant about the critical and transformative capacity of social science.

### *Critical Realism and Social Research*

These general ontological claims about the character of the social furnish grounds for rejecting positivist, social constructionist, and postmodernist rationales for social research. But critical realists make a strong distinction between such transcendental statements about key ontological features of social reality and the necessarily fallible character of particular epistemologically grounded knowledge claims about specific features of the social world, including particular causal mechanisms and their combined effects. An adequate social science must be premised upon a search for social, cultural, and agential entities with specific causal powers, coupled with recognition that such powers will operate in a mediated and cumulatively interactive fashion as they constitute open and evolving configurations. The elucidation of such entities, powers, and interactions is inevitably provisional, but cannot be grounded in empiricist induction or covering law deduction (i.e., where an event is explained through deduction from a more general law and initial conditions). Instead it must be developed through a theoretically guided engagement with theoretically salient findings.

Ray Pawson and Nick Tilley translate this in a practical way as the analysis of relationships among mechanisms, contexts, and outcomes. This can be unpacked as a search for entities with particular causal powers (mechanisms) that operate in distinctive ways when accompanied by other entities that may trigger, mediate, or contradict these powers (treated in summary fashion as contexts) to produce distinctive effects (outcomes). When the theoretically guided engagement works from

outcomes and contexts to develop an account of possible mechanisms, critical realists characterize this as *retroduction*. When it works from posited mechanisms through contexts to explain specific outcomes, it is termed *retrodiction*. These terms seek to capture the theoretically driven but open-ended character of social research, a feature underlined by recognizing that social research programs involve both retroduction and retrodiction.

In thinking about this “mechanism, context, outcome” formula, the distinction between mechanisms and contexts is sometimes construed as an ontological distinction between entities with intrinsic properties and powers and surrounding but contingent circumstances. One problem, however, is that in an open system and in the absence of experimentation it is difficult to sustain the distinction in these terms. Instead, those involved in the substantive analysis and middle-range theorizing that characterize social research are likely to make this distinction on pragmatic grounds related to the specific focus of the research.

What, then, are the implications of these methodological guidelines for specific styles of research or research design? First, much quantitative and survey research is constructed and justified in terms of positivist protocols that are attacked by critical realists. Statistical regularities are often treated as qualified forms of constant conjunction and theorized in terms of covering laws, while surveys often provide little evidence about contextualization or temporal sequencing. Meanwhile, case studies are relegated to a subsidiary exploratory role, subordinated to the requirements of statistical generalization from large data sets. It should be noted, however, that some forms of quantitative research and statistical analysis do address contextualization and/or temporal sequencing, and critical realism has inspired some such efforts to model the complex, contingent, and multilevel outcomes of causal mechanisms.

Meanwhile, qualitative and ethnographic research is often strong on contextualization and temporal sequencing while repudiating a search for covering laws. Such research is usually conducted under the auspices of social constructionist or post-modern theorizing, but critical realists dispute their one-sided focus on actors’ interpretations or cultural discourses and their relativist disregard for the differential adequacy of contending explanations,

which impoverishes the analytical and explanatory scope of case studies. When qualitative and ethnographic researchers are guided by critical realism, then, they endeavor to conduct that research in ways that overcome such limitations.

Critical realism therefore contests the polarized debate between positivism and constructivism as philosophies of social science and offers guidance that cross-cuts the associated quantitative/qualitative divide in research traditions. Critical realist reassessments of both quantitative and qualitative methods are compatible with an explicitly mixed methods approach to social research, but do not offer a blanket justification for eclectic mixing of quantitative and qualitative methods. Instead, they set some quite stringent criteria for assessing the adequacy of specific research designs, whatever the mix of methods involved. These emphasize explicit theorizing, identification of causal processes, appropriate contextualization, attention to temporal sequencing and interaction effects, and critical contextualization of actors’ accounts.

### Application

Critical realism values several standard features of case study research design: investigation of actors’ discourses and negotiated meanings; concern to set specific social processes in context, both within and surrounding the case; and attention to the sequencing and dynamics of social processes over time. But it also recommends other features that have a more disputed currency: willingness to deploy mixed methods of data collection and analysis; reliance on explicit theorizing to draw out the wider implications of specific case studies; and critical engagement with the limiting as well as penetrating features of actors’ accounts. Together these features explain why critical realists take case studies seriously and why case study researchers appear increasingly attracted to critical realism.

This engagement is recent but already productive. One result is a clearer specification of the components of explicit theorizing that may inform the design and interpretation of case studies. Stephen Ackroyd compares four different case study research designs and highlights the distinctive analytical focus and explanatory leverage afforded by each. Intensive, tightly focused, single case studies provide the basis for fuller understanding of the

operation of a specific causal mechanism. More extensive, holistic, single case studies offer the prospect of exploring interacting and stratified mechanisms operating in specific sequences and nested contexts to produce distinct outcomes. Intensive, probe-like, multi-case studies allow the examination of interactions between a specific mechanism and varied contexts. Finally, more extensive multi-case studies allow researchers to trace the ramifications of well-understood mechanisms as they interplay with quite varied contexts.

Thinking in these terms encourages consideration of the ways in which different case study research designs may enable distinctive mixes of retrodution and retrodiction, underpinning the discussion of wider theoretical implications. Appropriate combinations of these designs should allow a cumulative understanding of fundamental generative processes, their interactions within the case, and their interplay with surrounding contextual features. This is also compatible with the “holistic modeling” approach to cross-case comparisons (both within multi-case projects and across published cases) advocated by Paul Edwards and Jacques Belanger, which emphasizes the role of configurations, contexts, and temporal sequences against any quasi-statistical aggregation of case study findings.

Another specific focus of discussion concerns a distinct approach to interviewing research subjects, a key resource in generating case study data. Ray Pawson and Nick Tilley argue that interviews should be “theory driven,” designed to explore, refine, and test the character of proposed mechanisms and contexts and the ways they link to outcomes. They suggest that this requires the interviewer to coach the informant on what is relevant through the character and sequencing of questions and the elucidation of areas of interest, highlighting the importance of connecting analytical agendas with actors’ own experiences and reflexivity. Thus researchers should pursue focused discussion of specific, apparently pivotal, processes and their varied interpretation within the setting. Furthermore, they may treat interviews in an iterative manner, as a cumulative series of opportunities to trace and probe the operation of key mechanisms and processes rather than as a series of discrete data collection points.

### Critical Summary

Critical realism provides a programmatic alternative to several other philosophies of social science, combining an ontology that recognizes the existence of stratified social mechanisms with distinct effects and a theoretically led, nonempiricist account of knowledge production. It therefore opposes the traditional dichotomies of positivist and constructionist epistemologies and the associated polarization of quantitative and qualitative methods. Its concern to explain social phenomena (events and experiences) in terms of the causal powers of particular social mechanisms and their complex interaction in specific contexts has important affinities with some traditions of case study research. However, the implications of this affinity for a distinctively critical realist conception of case study research remain underdeveloped and are only now being discussed.

## CRITICAL SENSEMAKING

---

The analytic framework of critical sensemaking offers an approach to understanding how individuals make sense of their complex environments. It builds on the concept of “sensemaking” in which individuals draw on social psychological properties to help make sense of the experiences that they encounter in organizations and society. Critical sensemaking puts the sensemaking process in context by including issues of power and privilege in the process of understanding why some language, social practices, and experiences become meaningful for individuals and others do not.

This approach to analyzing meaning in organizations is compatible with a case study format in that sensemaking happens within a social context and as an ongoing process. It also occurs within a broader context of organizational power and social experience. As a result, the process of critical sensemaking may be most effectively understood as a complex process that occurs within, and is influenced by, a broader social environment. The descriptive, detailed approach of case study analysis is particularly suited to the analysis of this complex process.

### Conceptual Overview and Discussion

Critical sensemaking is an approach that evolved in part from Karl Weick’s sensemaking framework. He has described sensemaking as a recipe that provides both a way to interpret the environment and a guide to action. A recipe can help to make retrospective sense out of observed behavior, or in a more active sense, a recipe can direct individuals on how to take action, manage situations, and create meaning.

Sensemaking introduced seven properties that influence how individuals make sense of the world around them. The sensemaking framework tells us that individuals make sense of their experiences through a process that is (1) grounded in identity construction, (2) retrospective, (3) enactive

of sensible environments, (4) social, (5) ongoing, (6) focused on and by extracted cues, and (7) driven by plausibility rather than accuracy. However, these properties on their own do not fully explain why some experiences, language, and events become meaningful for individuals while others do not. Individuals do not make sense of their experiences in isolation from their broader environments. For example, some individuals within an organization may have more influence on meaning than others. Individuals with more power in organizations may also exert more power on the sensemaking of organizational members. Critical sensemaking provides a lens through which to analyze the power relationships reflected in these inequalities within organizations and the consequences of those power effects for individuals.

Jean Helms Mills and Albert J. Mills developed the concept of critical sensemaking by combining the ideas of sensemaking and organizational power in an analytic approach that offered a more complete picture of how individuals process their experiences. Critical sensemaking argues that the analysis of sensemaking needs to be explored through, and in relationship to, the contextual factors of structure and discourse in which individual sensemaking occurs. Although individuals are making sense of their day-to-day actions on a local level, the concept of organizational power places local meanings in a broader understanding of privilege. Critical sensemaking draws on Mills’s organizational rules theory to offer an analysis of how these actions are determined. Organizational rules focus on social practices that determine the ways in which individuals organize and the manner in which “things get done” in an organization. However, the rules also set limitations on individual sensemaking and actions. From that perspective, rules provide a preexisting sensemaking tool that contributes to the plausibility of an interpretation or the likelihood of a cue to be extracted as meaningful. The incorporation of organizational rules into the critical sensemaking framework also introduces the concept of meta rules to sensemaking practices. These rules (including privatization, competition, and globalization) are broad in scope and represent points of intersection among a number of formative contexts.

Critical sensemaking also highlights the influence of organizational rules on individuals. These rules can be in the form of either formal or informal

organizational rules, and they reflect processes that impose order through organizational routines. Inasmuch as rules inform our understanding of how organizations may retain unity and cohesiveness, they also constrain the ways in which individuals may act and the possibility of appropriate interpretations of meaning. This perspective within a framework of critical sensemaking provides insight into both the power of the actors enacting rules, and the constraints under which these rules are introduced to the organizations. Although powerful actors in the organization may set the direction for the rules that will provide a sense of cohesion within the organization, they are themselves constrained by meta-rules and formative contexts that limit the availability of alternatives they may select from within a broader formative context.

Formative contexts are the institutional and social practices that shape a society's routines. They are structures that limit what can be imagined and done within that society. Critical sensemaking positions the formative context as a link between dominant social values and individual action. While no one formative context is necessary or fixed, some are privileged within society above others. Therefore, they represent a restrictive influence on organizational rules and individual enactment of meaning through the privileging of these dominant assumptions. Formative contexts, and the related organizational rules, are both productive of, and produced through, discourse.

By introducing the dimension of formative contexts, the critical sensemaking framework creates space for a discussion of how the macrolevel context in which individuals operate affects the cues they extract, the plausibility of various text and narratives, and the nature of enactment.

### Application

Typically, an investigation of critical sensemaking processes would start from, or at least relate to, an important organizational event. This event might be the arrival of a new CEO, a merger, layoffs, expansion, or anything that could have disrupted the existing organizational routines. Helms Mills describes these sensemaking triggers as "organizational shocks" that create ambiguity in the organization and force individuals to make sense of things differently.

In her research involving a Canadian community college undergoing organizational change, Amy Thurlow looked at that organization's sensemaking around a significant financial investment. The college had received a \$123 million investment from the provincial government at a time when other postsecondary institutions in the region had experienced a decrease in government funding. This investment came as a response to the college's strategy to convince government that it should become a more modern, national-caliber college. During the 5 years leading up to the announcement of the investment, the college renewed its curriculum, changed its mission and vision, and restructured the organization.

The college's CEO at the time had made the strategy to secure increased funding a cornerstone of his change agenda. The strategy was titled "getting to yes," yes being a positive response from government indicated by the amount of the investment. From the college's perspective, there is no question that the \$123-million-dollar investment by the provincial government translated into an interpretation of change as "successful" at that organization. This marked an important milestone for the college. As one senior manager said, "The \$123 million changed everything—the way we saw ourselves, the way the province saw us, the way the universities looked at us, everything."

As sensemaking is not a linear process, analysis does not happen in a particular sequence. As well, the seven properties of sensemaking are not all equally visible in the process of individual sensemaking. At times, one or more of the properties may play a more significant role in influencing sensemaking than others. For example, in her research Thurlow found that language that described financial pressure was used by management when presenting the need for organizational change to the community college employees. The consequences of not "getting to yes" were clear: The survival of the organization was at stake.

This threat to job security was not new to college employees. At the outset of the change process at the college, six campuses had been completely closed. These were all rural campuses, and the jobs that were lost in those areas would not be easily replaced. As a result of that experience, employees in the rural areas in particular also equated change with the threat of job loss. Even though the CEO

of the college emphasized that there would be no further campus closures, employees were uneasy about job security. The previous campus closures had been positioned as essential to the overall growth and survival of the organization at that time. Nevertheless, the impact on the sensemaking process of the employees who remained was significant. As one employee said, "It contributed to the low self-esteem that characterized the identity of the organization."

That previous experience informed the sensemaking of a number of individuals, particularly at rural campuses. Even after the investment was announced by government, there were several campuses that were cynical about whether or not the money would actually appear.

Although some properties may become more visible from time to time, the seven sensemaking properties may also influence individual sensemaking simultaneously. For example, the property of enactment may become visible in a particular sensemaking process, but that same enactment of meaning may influence the plausibility of other actions, and simultaneously the construction of individual identity. As individuals enact their beliefs, they also make sense of them. And in effect, the use of language in the describing of an event enacts the construction of sensemaking about the event. As a result, individuals within organizations may not make sense of the same event in the same way. To that end, there is no one "right" meaning attached to a given experience. Critical sensemaking offers a frame of analysis that looks at actions and beliefs as driven by plausibility, not accuracy.

*Plausibility* essentially refers to a sense that one particular meaning or explanation is more meaningful than others. It feels right within the range of possible explanations available to sensemakers in a given situation. There is no specific definition of what makes a particular explanation plausible; however, Weick suggests that options make most sense when there are no better alternatives, other individuals seem enthusiastic about this alternative, other individuals or organizations have taken this same perspective, and/or this explanation resonates most closely with existing identities and perceptions.

In the community college example, the influence of the \$123 million investment reached across the

organization and outside of it. The most immediate effect was the legitimating of the change initiative that the college had embarked upon 5 years before. With that came an important contribution to the construction of identities both for the organization and for individuals within the organization. In particular, the external validation of the college, particularly in comparison to its competitors, had significant influence on how individuals made sense of the effects of change.

In this example, organizational members made sense of change through several interconnected elements. The investment provided an important cue that influenced sensemaking processes. The image of the organization changed externally, and the internal identity of the organization began to follow suit. This cue was also important in enhancing the plausibility of the change agenda in the organization. External validation of the work being done at the college made the repositioning strategy of the organization more plausible, and the social and ongoing nature of sensemaking reinforced the possibility that the new identity was real. The investment strategy was also championed by an individual within the organization who demonstrated discursive power in presenting the narrative of change, extracting cues, and influencing identity construction.

As demonstrated in this example, the critical sensemaking perspective suggests that plausibility is also enhanced by those same factors that privilege some discourses above others. The discursive power of the actor proposing a particular manner in which to make sense of an experience, the access individuals have to a plurality of discourse, and in fact, the access individuals have to the proposed meaning, all influence plausibility. At the community college, the fact that the CEO set a vision, and the organization supported that vision, speaks to the impact of this individual on the language and direction of change at the college.

Although organizational shocks may prompt individuals to draw on a variety of cues from their changing environments, one of the major concepts within critical sensemaking (and sensemaking itself) is the centrality of identity construction to sensemaking processes. Change within organizations may cause individuals to ask questions such as, "Who are we?" or "How do we do things?" The way in which individuals make sense of these

questions impacts their understandings of their own identities and that of the organization. Identity construction is a key component in the process, not just because it influences individual sensemaking, but also because it influences how the other six properties are understood by individuals.

Sensemaking describes a process of identity construction whereby individuals project their identities into an environment and see their identities reflected back. Through this process they come to understand what is meaningful in their own identities. Critical sensemaking shows us that organizational power and dominant assumptions privilege some identities over others and create them as meaningful for individuals. For example, the identity of a “good employee” may be privileged within an organization through texts, language, rules, and more, that emphasize the characteristics of this identity. The construction of this identity may include rules about how employees should function within the organization. Employees may also be encouraged to draw upon cues from their work environment and reflect an identity privileged through other similar organizations or a broader social context. As with all sensemaking, this exercise in identity construction occurs within a social and ongoing process.

### Critical Summary

Critical sensemaking provides a framework for understanding how individuals make sense of their environments at a local level while acknowledging power relations in the broader societal context. The critical sensemaking framework takes a very complex combination of variables, including social psychological properties, organizational rules, and the formative context in which organizations exist, and offers an analysis of how these forces combine to allow individuals to make sense of their environments and take action on a day-to-day basis. Critical sensemaking is useful in analyzing the relationship between individual actions and broader societal issues of power and privilege. It also provides a lens through which to view connections between the formative context, organizational rules, and properties of sensemaking that influence how individuals make sense of the world around them. It is, however, a complex process that may evolve in different ways within different contexts.

Given the focus on power relations, this method of analysis is most useful to postpositivist research.

## CRITICAL THEORY

---

Critical social sciences and critical social theory are related to and stem from Critical Theory tradition.

The concept of “Critical Theory” refers to the intellectual work by philosophers, sociologists, and social thinkers that became known as the Frankfurt School. The Critical Theory is rooted in social philosophy and social sciences history. Critical Theory emphasizes the norms, values, and meanings in the constitution of knowledge of society, on the one hand, and the roles of science and scientists in changing the society, on the other. Critical theory today has broader meaning and carries several notions, layers, and variety of understandings of the term *critical* itself. Over recent years the critical theory has been renewed by the impacts of social theory and social philosophy such as feminist thinking, postmodernism, and critical realism.

### Conceptual Overview and Discussion

The history of Critical Theory is important for understanding the role and the position in critical theory in social sciences and in case studies. Originally, Critical Theory linked philosophy closely to the humanities and to social sciences by emphasizing the contextual empirical social research and normative truth claims, morality, and justice simultaneously, all in the same research agenda. The term *Critical Theory* with capital letters is used when referring to original ideas, and *critical theory* when referring to more general critical theories in social sciences that have closer or more distant relationship with the original specificities of Critical Theory. The newer versions of critical theory have developed their own forms of critical practices and critical research agendas through several current debates. Key conceptual background ideas and overview are needed for understanding the contemporary varieties of critical theory in case studies and in social sciences in general.

Critical theory has strong roots in specific fields and developments within European philosophy, on the one hand, and historical time and societal situation on the other. In its historical form the idea, tradition, and concept of Critical Theory refers to the intellectual work by philosophers, sociologists, and social thinkers that became known as the Frankfurt School. The Frankfurt School was located at the Institute for Social Sciences (Institut für Sozialforschung) at Frankfurt am Main University in Germany in the 1920s. During World War II, the Institute was brought to New York, to

Columbia University; it returned to Frankfurt in 1950s, with Max Horkheimer as director of the Institute of Social Research. Major thinkers in the Frankfurt School group include Max Horkheimer, Theodor W. Adorno, Walter Benjamin, Herbert Marcuse, Erich Fromm, and Jürgen Habermas.

The Frankfurt School’s Critical Theory has the scientific and practical intentions to relate the knowledge achieved through research and mundane social life with each other. In practice, empirical research adopts the critical reflection as method, in addition to theoretical aims. According to Critical Theory, the research needs to relate the philosophy and the social sciences and their ways of describing the world through explanation and understanding. The scholars involved in the early stages of the Frankfurt School were concerned with the complexities of the economic foundation of society, the political–legal factors of society, and the intellectual life in community and society in general. In research, the aim was to combine moral views and practical questions and implications of social research.

The Frankfurt School and Critical Theory grew influential in the social sciences from the 1930s onward. Critical Theory diverged from the positivist preferences of German philosophical circles in the 1930s. The enduring ideas in Critical Theory thinking have been the analysis of structural relationships of power, control, and discrimination mediated through language, and the understanding of the activity and role of the knowing subject in these processes. These ideas have since the birth of Critical Theory been developed elsewhere within the philosophy of social sciences, and from many different epistemic positions, with the overarching label of critical theory. However, not just any theory or research is critical, even if it would label itself so. Whether the original idea of the Frankfurt School or more broadly defined versions of critical theory is being discussed, the general aim of critical theory is to explore the world with a broader lens than, for example, hypothetico-deductive method enables.

The three criteria set for research in Critical Theory were the following: critical theory research must be simultaneously *explanatory*, *practical*, and *normative*. Research needs to explain the object of study in a nomological, interpretative, or historicist way. Research needs to be practical and not

abstract empiricist by orientation. Research needs to be normative, that is, its results should indicate what ought to be. Normative social science admits to bias and subjectivity of research, unlike positive social science. The distinction between positive and normative social science rests on the so-called fact/value dichotomy, which no longer prevails in philosophy. In addition to this, there are also other reasons that critical theory does not fully follow the original thinking of Critical Theory.

The original Critical Theory emphasized the integration of theory and practice so that individuals can then reflect on the results and learn from them in order to be able to change their lives, habits, and surrounding societies. Critical Theory in general distances social sciences research from the assumptions and methods of the natural sciences by emphasizing the role and position of norms, values, and meanings in the constitution of knowledge, and the active roles of science and scientists in changing the society. Theodor Adorno, who was influential in Critical Theory, underlined immanent criticism as the key method for Critical Theory research.

Immanent criticism in research means thorough critique, both throughout and within the research project. Immanent criticism as method challenges both the belief systems and social relations. The method aims not for standard variable-based comparisons but to establish and show discrepancies in thinking. Habermas, a notable figure in critical theory, emphasizes the theory of rationality and with that sets a standard against purely interpretative, hermeneutic, and relativist positions in research. The contextual lifeworlds and their analysis were originally one of the key ideas in the Critical Theory by Horkheimer and also by Habermas.

Several substantive issues are central to critical theory in general. First is the domain of *methodology*, not as concrete practices and methods of research but as philosophical prerequisites and approaches embedded in the practices. The domain of *modernity* and its substance and understanding of modernity and postmodernity is also important, as is the domain of *critique*: How and in what ways could and should critical theory be related to practice and to everyday lives? The relationship between “empirical data” and theoretical framework is complex in critical theory, and critical

theory’s overall research setting is a mixture of normative and practical aims. In the broad, contemporary, but also in the narrow, traditional senses a critical theory provides the descriptive and normative bases for social inquiry aimed at decreasing domination and increasing freedom in society in all its forms. Critical research at large consists of a broad field of inquiries, and it has close connections to the philosophy of the social sciences and in a different way to Critical Theory as well. For these reasons, the method of critical research is also closely connected to specific traditions within social sciences and philosophy.

Critical Theory acknowledges the existence of structures and mechanisms of the world. These structures and mechanisms are seen as existing beyond the pure constructivist idea, as elements in society and emergent and knowledgeable to the researcher. In other words, neither the original form of Critical Theory nor most of the present critical theory support the ideas of the social constructionist approach without reservations. Even if critical theory acknowledges the existence of several understandings of the world, it usually emphasizes the existing structures and mechanisms related to these structures. The values involved in a given critique are always partial and also subject to self-evaluation. Critical theory brought forward the critique of positivism, and emphasized a critical approach to social analysis that would promote social transformation.

Craig Calhoun has written widely on Critical Theory. He suggests that critical theory generates critique broadly in three different ways: in engagement with the contemporary social world, in engagement with the historical and cultural conditions of intellectual activity, and in engagement with the reexamination of categories and frameworks used in research. In critical research in social sciences, the relationship between empirical data and theoretical framework is seen as a very complex one: the world—be it the economy or social group—and theory describing this world are not seen as apart and separate from each other as in positivist research tradition. However, the world, its units, or actors—or objects of analysis—are not seen in Critical Theory as socially constructed, either, or as dependent only on the speech acts and constructions that are continually reconstructed and reinterpreted.

Methodological reflexivity is another feature of critical aspect in research: Methodological reflexivity includes the questioning of what is known about the world and in what ways. The conceptual tools common to critical research relate to the centrality of language, the interpretive approach to human behavior, and the importance of self-reflexivity. The questions of how and in what ways critical theory is to be applied at a practical level in research remained somewhat unanswered, or of lesser interest, within critical theory for a long time. In critical theory, the law-like generalizations concerning society or the research target are seen as both highly problematic and questionable. According to critical theory, the nature of any social scientific theory is shaped by the historicity of the study objects it seeks to explain.

Calling research “critical” in research settings is not enough theoretically or methodologically for critical research. There are specific methodical and methodological issues that relate to and are crucial for the theoretical ideas of critical research. Such specific contemporary research methods are, for example, *critical discourse analysis*, *genealogy*, and *critical hermeneutic approach*, all of which can be used in case study research. *Critical discourse analysis* (CDA) focuses on analyzing structural relationships of power, dominance, and control as manifested in language. As an example, the analysis of discourse opens up an issue on social problems as they are largely constituted in language, and for their part, discourses constitute society and culture. Most critical discourse analysts subscribe to Habermas’s notion of language as a medium of social force, power, and legitimation of organized power. *Genealogy or genealogical inquiry* examines the conditions under which the different ways of interpreting and evaluating ourselves have come to exist. The purpose of the genealogical method is to analyze and excavate the taken-for-granted interpretations of concepts, theories, and methods used in research. The *critical hermeneutic approach* acknowledges the question of power, the potential misuse of language, and recognizes the importance of communicative aspects in research. The critical hermeneutic approach analyzes so-called latent structures and rules of meaning that underlie social practices and subjective meanings. These structures are latent, that is, they are not restricted to the agencies’ discursive knowledge, and they are

independent of their subjective intentions and meanings.

A challenge for any researcher trying to establish critical research in empirical settings in case study or in general is to find ways to link the detailed analysis of research materials to wider societal and social structures and power relations. There are different ways to do this: Consider the subject in wider context and focus on wider structural relations and examine the social processes. Ethnography offers one way to handle the complexity of the theoretical views of critical theory, but does not on its own stand for critical research.

In research settings, a critical theory approach means a tight connection between the method and methodology, various theoretical discussions, and ensuring the complexity of data analysis. Therefore, no single clear how-to pattern for critical approach in empirical settings can be given, as there are varieties of ways to do critical analysis in case studies. Case study settings offer one way of handling the complexity of data materials and multilevel relationship with the key ideas of critical research.

### Application

Application of critical theory can take many forms in case studies. The cases do not necessarily need to be empirical by nature, such as firm, company or social group, or individual. Cases can also consist of a time-limited process or phenomenon. Two exemplars of critical theory applications that can be considered as case studies are Seppo Poutanen’s analysis of lack of dialogue between critical realism and poststructuralist feminism, and David Boje’s re-analysis of research on Nike, Inc.’s manufacturing operations in Vietnam.

Poutanen analyzes a dialogue carried on by economists and feminist social theorists in the journal *Feminist Economics* between 1999 and 2003. The topic was the attention to philosophical ontological analysis in feminist theories and in critical realism. This article is an example of a time-limited theoretical case that uses a genealogical method in the analysis of a process of dialogue that took place in journal articles over a 4-year period. Poutanen analyzes the dialogue with the help of analytical philosophical argumentation and shows that in spite of the participants’ best efforts and the high quality of their contributions,

the overall result leaves a strong impression of a kind of shadow-boxing. In the spirit of critical theory, Poutanen concludes that there is a need for real, open dialogue that might shake up the ontological and epistemological cornerstones of differing positions.

Boje's article includes both empirical materials and the issues taken up earlier on revisiting the theoretical standpoints for research. Boje analyzes the case described by two colleagues on Nike's salaries in a Vietnamese factory, where the argument was based on empirical evidence that the Nike subcontract workers in Vietnam are able to save 44% of their monthly wages as discretionary income. Boje re-analyzes the available data, readjusts the calculation procedures, and reveals the method problems in the original article, which grossly distort the results presented. In a critical theory spirit, he then opens up the issue for normative and value judgments on salary levels in multinational corporations.

### Critical Summary

New challenges for critical theory and critical research are being put forward by the complexity of the connection between theory and practice, the possibilities opened up by feminist and emancipatory critique of social theory in general, and recent epistemological debates in the social sciences. Case research settings, with a demand for complexity of empirical materials and constrained time-space approach, might open up fruitful avenues for furthering critical theory and critical research.

## CROSS-CASE SYNTHESIS AND ANALYSIS

---

Use of the case study in the natural and social sciences began in the early 20th century with the establishment of the concept of a *case history* in medicine. The case study is also used outside of the natural and social sciences in education, educational evaluation, and as a teaching method in business and law. In the contemporary social sciences, the case study can be a single case or multiple cases. One method of studying multiple cases is the cross-case design proposed by Matthew B. Miles and A. Michael Huberman. While Miles and Huberman are credited with stipulating the precise logics and mechanics of this approach, it has a long history and wide usage beyond their specific formulation and is a general qualitative research strategy. While the single case study emphasizes close inspection and description of one case, the cross-case is used to reinforce validity, support generalizability, and promote theoretical elaboration. In psychology, Sigmund Freud's theory of psychoanalysis is perhaps the most widely known example of cross-case synthesis and analysis. In sociology, a cross-case methodology is the logic inherent in Barney Glaser and Anselm Strauss's constant comparative method for the generation of grounded theory.

### Conceptual Overview and Discussion

Miles and Huberman propose two interdependent strategies for cross-case analysis: variable-oriented analysis and cross-case analysis. They formulate the cross-case method as follows. First, the researcher conducts two or more descriptive case studies using the process known as *thick description*. Then the

researcher examines a particular case for emergent patterns. The second step involves identifying the presence or absence of and alternatives to these patterns occurring in one or more other cases. Doing this analysis across a number of cases allows for the identification of similarities and differences across the cases and the identification of common themes.

Miles and Huberman recommend that researchers then subject the themes across all of the cases to variable-oriented analysis. First, standard variables across the cases and within the themes are identified. Each case is then written up and presented in a matrix, in as much detail as possible, with reference to these standard variables. Finally, a meta-matrix is created through synthesis or “stacking” of the variables across all of the cases. In this way the researcher retains both the detail of the individual cases and partial but overall explanation of a number of cases.

A good example of this method can be found in Molla S. Donaldson’s study on the quality of healthcare in the United States. The results are based on thick description and the analysis of 45 healthcare delivery units, one of which was in Canada and one other in the United Kingdom. Interviews were conducted in seven cities in a variety of types of healthcare delivery locations such as hospitals, primary care centers, and family physicians, with large numbers of persons including some 270,000 patients and 15 medical teams. The protocol suggested by Miles and Huberman is followed closely: 14 variables are identified and then refined, through cross-case analysis, into eight themes. Generalizations about how healthcare delivery systems function and broader issues such as the sources of excellence and innovation among them as well as suggestions for future training of healthcare professionals and formulating healthcare policy are then made.

The cross-case method of Miles and Huberman is rarely followed in its entirety by contemporary researchers. Researchers interested in moving beyond description and extending the generalizability of their case study will invariably analyze one or more cases. A more widely used approach is the constant comparative method of Glaser and Strauss. They provide five compelling reasons for the use of comparisons across and within cases: (1) to ensure accuracy of the evidence, (2) to establish

the generality of a fact, (3) to clarify the relevant particulars of a case, (4) to test theory, and (5) to generate theory.

Once themes in the data and their associated concepts have been identified, Glaser and Strauss propose four steps in the comparative process. First, they compare the various incidents wherein the category was identified. This involves comparing the extent to which a concept (e.g., “social loss”) in one case occurs in other cases and then comparing the different aspects of each incident across cases. Second, they integrate the concepts and their properties. This involves noting relationships among and variations within the categories and their variation within and across the cases. For example, when does the concept of social loss occur in different cases and under what conditions? Third, they delimit the theory, once the patterns of relationships within the categories have become apparent and some relationships become more evident than others. The number of categories and their properties can therefore be reduced, and this leads to broader generalizations. Finally, they write the theory. In the act of writing, the relationships between the categories and their properties change because researcher understanding is modified and altered during the writing stage. The writing stage is thus regarded as part of the research process.

### Application

As a basic method for generalizing beyond the individual case, cross-case analysis and synthesis are ubiquitous in qualitative research. Robert Yin provides three examples of the cross-case method: One is a single case that is drawn from a larger comparative study of eight cases, the second covers two cases, and the third covers seven cases. The first describes the Korean company Samsung and its strategies in developing and marketing microwaves, which in the larger comparative study is used to demonstrate principles regarding Third World manufacturing and growth. This is a good example of how the initial case sets the precedent for the latter cases because it provides keys to the analyses of the other cases and is thus the basis for the entire study.

The second presents two cases of types of industry (aeronautic and microelectronics) and examines

the role of government funding in the development of industrial planning. This study demonstrates that even two cases are a useful cross-case method because the second case, while still limited in strength, allows for greater generalizability and validity than would be possible for only a single case. This is a particularly important strategy when the research contravenes conventional wisdom.

The third is a study of seven different locations where the government had initiated the same program for housing developments. This study demonstrates how to identify themes across a number of cases. Detailed explication of the seven cases is provided only in an appendix. Rather than discussing each case, the researcher integrates the evidence from all of the cases and identifies the common themes among them. From these emergent categories, a number of generalizations regarding the specific program are stipulated. These are then used to draw general conclusions about the limitations of implementing federal policies without detailed knowledge of and consultation with local politics and interest groups.

### Critical Summary

There are potential weaknesses that hinder the cross-case study. These are most critical for data collection on the first case during the early stages of the research, and have an impact on outcomes regarding judgments on the validity and generalizability of the findings. The concern for validity may occur because as the number of cases increases, the amount of data collected on each case is likely to decrease and chances of error (validity) in the information are therefore increased because particular aspects in the one case may be overlooked in the search for commonalities across the cases. These problems are further exacerbated by the fact that the number of case studies undertaken is usually limited by the amount of resources needed versus what is available.

A second question regarding validity refers to the amount of evidence required to support the researcher's claims. As with all case studies, it is impossible to know whether or not all of the relevant cases have been observed. When theorizing to a finite and relatively small population or a single case, one or a few cases will suffice; however, in attempting to theorize beyond the single case or to a relatively

large finite population, problems may arise. Martyn Hammersley suggests the generalizability of the cross-case study can be improved in the following ways: select cases that cover some of the main dimensions of suspected heterogeneity in the population, make brief investigations of one or more other cases in order to assess the ways in which the primary case is or is not representative of the larger population, and, finally, compare the findings with studies that have been carried out by others on cases in the same population in the same time period.

Another source of potential weakness of the case study is unrepresentativeness or the extent to which the study accurately represents the population it is intended to describe, explain, or theorize. Although we can never know with certainty whether or not an account is true, we must attempt to judge the adequacy of the evidence provided in support of those claims. Hammersley provides three guidelines. The first concerns plausibility and credibility: Does the explanation make sense? Is it plausible to other researchers? The second involves the centrality of the claim to the argument presented: The more central the claim is to our explanation, the more plausible it must be and the more evidence is required to support its plausibility. Third, different types of claims require more or less evidence: If your claims have significant consequences, then they require additional evidentiary support. The stronger the claims, the stronger the evidence required in support of them.

## CROSS-SECTIONAL DESIGN

---

*Cross-sectional design* refers to studies in which data are collected at one time period only. The aim is to access, at one time point, a representation of the population of interest. This contrasts with longitudinal design where the aim is to collect data at several time points. In research areas that are particularly concerned with development trajectories and age or experience differences, as in education and developmental psychology, the cross-sectional design is often considered as an alternative to longitudinal design. For example, where a longitudinal study of children's reasoning abilities would collect data from a group of children at several time points—for example, at their third, fourth, and fifth birthdays—a cross-sectional study would collect data at only one time period and include data from different children who are 3, 4, and 5 years old.

### Conceptual Overview and Discussion

The broad meaning of cross-sectional design—data collected at one time period—can present some definitional challenges. The distinction between data collected at one time period and data collected over time can be a difficult one. The definition of a single time period can vary from a single visit to a site on one day, to visits conducted over a whole year or more. In the case of longer time periods, the distinction is primarily in the intent of the study. If change over time is an aspect of the study—for example, if changes in nursing practices are explored over one year as a hospital implements new policies—then the study is employing a longitudinal design. If, on the other hand, the intent is to explore nurses' reactions to the variety of cases in a hospital emergency room during one year, not the changes in their reactions, the study would be considered primarily cross-sectional.

From this broad perspective, cross-sectional design is applicable to all types of case studies. Using Robert Yin's classifications, cross-sectional designs can be applied to both single and multiple case studies, including those that are holistic and embedded. For example, a single holistic case study of a marketing firm would be considered cross-sectional if it is conducted over one defined

time period and includes a cross-section of employees from all levels in the firm. This approach can be extended to single embedded case studies and all forms of multiple case studies. In specific reference to the multiple case study, John Gerring uses the term *cross-sectional design* to refer to situations where many cases are being used for cross-case analysis without temporal variation.

From a developmental perspective, cross-sectional case studies should include participants selected from different stages in their trajectories (e.g., ages, grades, or years of experience). In a single embedded case study this could take the form of a whole-school case with embedded groups at each grade level. In a multiple case study this could be accomplished through defining each class as a case and choosing classes from different grade levels.

In these developmental situations, the cross-sectional design is often used as a substitute for a longitudinal design. Rather than comparing the same students, for example, as they change over time, changes are explored by looking at groups of students of different ages. The primary reasons for conducting a cross-sectional study rather than a longitudinal one are the savings in cost and time associated with collecting data. The drawbacks, however, include the inability to distinguish between true age-related changes and age differences due to other factors, including cohort factors, and the inability to understand individual change. Individuals may still be defined as the unit of analysis, but individual change cannot be analyzed.

In other situations, however, cross-sectional design may be the only appropriate structure. Researchers interested in the implementation of an anti-bullying program in a school may want to use case studies to understand the most appropriate age for the program. They would choose a multiple-case design with cases at different grade levels. It would be inappropriate to study the same students receiving the program year after year.

In addition, there are also hybrid varieties where cross-sectional designs are followed through time. Gerring describes a time-series cross-sectional design where several cases are studied, each at several matching time intervals. These can also be described as cohort-sequential designs. An example might include three case study school classes, one in the first grade, one in the second, and one

in the third. If they are studied for 3 years, cross-sectional data are available for students in first through fifth grades, thereby saving time over a true longitudinal design. In addition, some of the cohort effects of a true cross-sectional design are lessened because cross-case analysis in the same grade is possible and individual change over time for students in different cohorts can be studied.

### Application

Zoe Barley and Andrea Beesley's study of successful high-needs rural schools provides a clear example of multiple holistic case studies applying a cross-sectional design. Six schools, in three states, were selected as case study schools to provide exemplars of success. A single visit was conducted at each school and included focus groups and interviews with community members, parents, school board members, teachers, and the principal—a cross-section of the school's stakeholders and decision makers. This is an uncomplicated example with the single time period approach applied unambiguously through a single visit to each school. It illustrates the use of cross-sectional design to ensure a broad and thorough understanding of the case from multiple perspectives.

In a similarly uncomplicated application of multiple case cross-sectional design in a developmental context, Shin-Ju Lin, Brandon Monroe, and Gary Troia interviewed and constructed case studies for 28 students, 4 students from each of Grades 2 through 8. In each grade, 2 students were identified as developing writers and 2 identified as struggling writers. Patterns in the differences between the two types of writers were traced across the grade levels. This case exemplifies the use of cross-sectional design instead of longitudinal design.

The approach taken by Lourdes Rodriguez and Francisco Cano in their study of university students' learning approaches and epistemological beliefs exemplifies a hybrid cross-sectional-longitudinal design. Their case level was a teacher education program, and two cross-sectional levels (students in their first and their final years of study) were studied at the same time period. In addition, participants from the first-year cohort were randomly selected to participate at a second time period (during their final year of study). Differences in epistemological beliefs by age and

program level were explored through both the cross-sectional sample and the longitudinal sample. The findings from this study also highlight the problematic nature of cross-sectional designs as some of the findings were evident in the longitudinal analysis and masked by cohort effects in the cross-sectional analysis.

### Critical Summary

Cross-sectional designs support the researcher in ensuring that a broad and complete sample of relevant case constituents are included while also providing a means of studying developmental effects without the extreme costs associated with longitudinal studies. It is an adaptable design structure, flexible enough to be used in both single and multiple case studies. Caution should be used, however, in its application as replacement for longitudinal study as cohort effects may limit effectiveness.

## CULTURAL SENSITIVITY AND CASE STUDY

---

Cultural sensitivity is the awareness of cultural factors that influence research. It requires researchers

to respect population diversity, understand the perceptions of a cultural group, and reflect on their own assumptions. Cultural sensitivity is a necessary prerequisite to developing cultural competence within the research setting; that is, the ability to make informed decisions when researching cultures different from one's own.

### Conceptual Overview and Discussion

Within the current climate of multiculturalism and plurality, research methods are needed that are culturally sensitive and can be used for working with diverse culture-sharing groups. Culture-sharing groups are those that have, for instance, common beliefs, behaviors, rituals, and communication styles. A culture might include ethnic groups such as a particular Indigenous tribe, or groups such as sex trade workers or skateboarders. Culture sensitivity requires researchers to develop knowledge about another cultural group and the skills and attitudes required to work with the group's members. Knowledge would include understanding traditions and practices such as initiation rites or specialized vocabulary. Skills would include learning verbal and nonverbal cues such as nicknames or hand gestures. Attitudes would include flexibility and patience.

Case study research enables researchers to investigate phenomena within a particular context. Pilot studies using this approach are particularly important for developing cultural sensitivity; they help researchers gain knowledge, practice skills, and develop attitudes to prepare for longer-term work involving a larger sample of the culture-sharing group. Establishing relationships with representatives of the group or gatekeepers will assist researchers to appreciate how cultural factors operate in the research setting and help in developing culturally sensitive protocols for activities such as accessing participants, gaining informed consent, or gathering data. Researchers need to assess their own values and attitudes about the culture, keep detailed field notes, and continually reevaluate personal reactions while working with participant groups. The development of rapport with culture members, based on trust and respect, can help mitigate miscommunication and false assumptions due to lack of understanding.

Researchers need to step aside from the traditional role of power in the research relationship and view participants as their teachers. Nonhierarchical ways of engaging with research participants can help establish respect for a culture's ways of knowing. For example, researchers who are culturally sensitive might adopt culturally appropriate approaches to sharing information, such as using talking circles with Indigenous participants to ensure each member has an opportunity to speak. Participants' theories about phenomena observed in the cultural setting inform the study and are placed alongside the researcher's theories for further discussion.

Representing the case in a culturally sensitive fashion involves the use of thick description and frequent member checks to show respect for participants' understandings of the phenomenon of study. Innovative and culturally sensitive ways of sharing knowledge about the case also are needed. Groups with oral traditions might receive researchers' comments in narrative format, for example. Researchers need to be reminded that transferring findings to a group outside of the culture may be disrespectful to both the community that offered to participate in the research and the group outside the culture. It cannot be assumed, for example, that findings from one group of Indigenous people can be used in another Indigenous community. Recommendations arising from the research need to be culturally relevant for the specific group.

### Application

Two examples of culturally sensitive case studies are described below. One study was conducted by Elizabeth Banister and Deborah Begoray in a Canadian Indigenous community; the second study, by Stephen Margolis and Valmae Ypinazar, took place in the United Arab Emirates.

Banister and Begoray's case study on adolescent girls' perceptions of sexual health began with a pilot phase to ascertain the needs of the culture sharing group: 10 14- to 16-year-old Indigenous girls attending the same rural secondary school—all from the same Coast Salish tribe on Canada's west coast. Access to the community was achieved through permission of the band council and the school principal. An Elder assisted the researchers

to gain knowledge about the Indigenous culture, including ways of sharing knowledge through storytelling and drawing. The researchers also attended school events, including the school picnic and graduation ceremony.

While the researchers were interested in developing a case study, members of the cultural group also wanted to benefit from the researchers' presence and gain expertise in matters of sexual health. The researchers learned how to work in traditional groups with members of different ages, to engage with the girls through techniques such as the creation of traditional crafts, and to invite the participation of the wider community through interviews with parents and other community adults.

Margolis and Ypinazar examined older Arabian Gulf Arabs' perceptions of religion, health, and illness to inform the delivery of culturally sensitive care for this community. The study sample consisted of 10 participants who were 65 years of age and over, Muslim, Arab, and residents in the United Arab Emirates for more than 50 years. Qualitative interviews were conducted in Arabic by two research assistants, both practicing Muslims and fluent in speaking Arabic and English. Interviews took place in the privacy of participants' own homes. Sharing a common religion and language and locating the interviews in a familiar space offered a culturally sensitive advantage to the research design.

### Critical Summary

Case study research offers a high level of contextual and specific knowledge. The use of case study methods can help researchers transcend ethnocentric attitudes toward cultural groups under study. Culturally appropriate research activities that are tailored to the needs of the community will contribute to rich understandings of the culture-sharing group and enhance the overall credibility of the study.

## *DASEIN*

---

Martin Heidegger's notion of *Dasein* is the central organizing feature of his existential phenomenology as formulated in *Being and Time*. Heidegger employed the notion of *Dasein* to distinguish his conception from *subjectivist individualism*, which views the self as a pure "I" or pure consciousness independent of body and world, and an *objectivism* that views the world as inert matter to be mastered and controlled by subjects. Rejecting this subject/object model, Heidegger situated being human in a domain that is neither objective nor subjective but as a relation—a form of being in the world. *Dasein* is practically rather than theoretically oriented; it is not a substance or a thing, but practically situated and interested human activity. Understanding and knowing are elements of being in the world and not of disinterested subjectivity. Although Heidegger eschewed epistemology or method, his conception of *Dasein* has had a major impact on social science research and on the nature of qualitative research.

### Conceptual Overview and Discussion

The basic feature of human being or *Dasein* is that it is *self-interpreting*. *Dasein* is the being that asks about its own being, which is what it is to be human. *Dasein* is the kind of being—the only kind of being—whose existence is a problem for itself. *Dasein* takes a stand on what is to be human. Human beings (*Dasein*) are unique because "their

way of being embodies an understanding of what it is to be." *Dasein* is activity. Being human means having to make sense of one's own existence to grasp one's own projects and prospects as one's own and to grasp them as part of one's own identity. This self-interpreting way of being is existence. Consciousness is not the condition of being but rather being is the condition of consciousness. Because our existential nature is the reason we can represent beings, consciousness presupposes existence.

For Heidegger's teacher Edmund Husserl, phenomenological philosophy began from the supposition of pure consciousness. Theory alone, not deficient ordinary understanding, made phenomena ultimately intelligible in their true nature. Husserl employed the modern ideal of knowledge free from presuppositions. By eliminating all our interests and involvements Husserl sought a pure intuition of things themselves. Heidegger rejected this approach. He held that we can only know the world because of our involvements. Knowledge requires presuppositions and context-bound understanding. Heidegger, in contrast, began with the idea that phenomenology was a clarification of fundamental understanding that was always already there. He suggested that humans do not originate meaning or the world as an individual ego or transcendental subject; these features precede us. The task of phenomenology, then, is not to provide a better understanding of theory but to bring to light what is already inherent in the lifeworld. Participants in the lifeworld already know the world through their own practical skill and mastery. They know

the world because they inhabit it and because they live in the world with others. Knowledge is a practical achievement. Our practical knowledge, however, is largely implicit, a kind of global know-how that precedes our conscious elaboration.

In opposition to Husserl, Heidegger termed this philosophical procedure *hermeneutical*. Heidegger used the term *hermeneutics* in a radically new way. It was not a special procedure or mode of inquiry; it was Dasein's basic mode of being. Hermeneutics originally began as a procedure for recovering the meaning of historically and culturally distant texts. This conception provided an alternative to the model of absolute certainty associated with subject-centered philosophy by claiming that we begin interpretation from a position inside of language and society and never can step outside of this interpretive frame. Heidegger took this model of interpreters enmeshed in language and society, which was also used by the human sciences in Germany, and generalized it to include everyday activity. Interpretation did not claim to uncover a self-identical object fully present to consciousness but was incomplete by its very nature. In objectifying some aspect of Being (as a posited being), it always left another aspect hidden. Interpretive phenomenology was not, however, idealist. Heidegger argued that the world exists independent of human beings but is meaningful only through our interpretations.

Understanding ourselves and our relation to the world is primarily practical. Human activity is engaged in the world and occurs in the midst of things. Dasein is historical. Humans are not primarily observers or pure minds who stand outside of time and place but are "thrown" into the midst of things. We are born into a family, a society, or a polity at a specific time and place, and this influences our understanding of the world. We understand ourselves and others through a shared language and through our participation and engagement in the world. We never know this world in isolation. Heidegger argued that the social world is always a *mitsein*, that is, a being-with world. There we encounter others who are not "for the sake of" something but others like ourselves, beings who interpret and act in the world.

Heidegger saw our primary mode of engagement as "care" or concern (*sorge*). Our commitments and concerns shape our lives. These might be considered our "essence." Yet we are not simply determined by

our circumstances and situation but play a role in determining our own existence. Heidegger saw Dasein as future oriented. We can form projects and plans based on the person we want to be. In order to act authentically, we have to take up the situation we are in and take responsibility for it. This aspect of self-determination is central to Heidegger's notion of authenticity. Being belongs to us. Our projects must also encounter the fact of death or temporality. For Heidegger, death was both a limit to life and that which makes life itself meaningful. Projects can never be infinite or unlimited in time; they have to account for our finitude. Heidegger argued that in order to make an authentic existence we have to discover our own unique historical destiny. We may have a fate, but that fate is determined not by the weight of circumstances but by our own interpretation of that world and its future possibilities. Ordinary Dasein, the average understanding, sometimes stands in the way of authenticity. Everyday life is largely one of conformity to social norms, a part of the mass society that Heidegger disliked. This "they world" of anonymous conformity conceals a genuine relation to one's self and one's destiny. In a world in which science and religion provide notions of infinite mastery or transcendental understanding, it takes courage to face finitude, something Heidegger called *resoluteness*. The latter, however, has some politically authoritarian overtones.

### *Heidegger's Engagements*

There are elements of Heidegger's account of Dasein, as well as in his own biography, that affirm this anti-democratic interpretation. The authoritarian turn is more than a simple account of authenticity. In Heidegger's view, "resoluteness" and "decision" are linked to "conservative revolution." This reading, however, requires a linking of Heidegger's conception of Dasein to his cultural critique of modern society and his notions of (conservative) cultural renewal. These issues of content apply more to the philosophical political context of Heidegger's thought and less on his influence on models of social inquiry.

### **Application**

Heidegger's conception of Dasein had both a direct and an indirect influence on case studies. His

philosophy represented a further elaboration of the interpretive method developed by advocates of the human sciences approach in the methodological conflicts of 19th-century Germany. He avoided some of the objectivism (and, to his mind, subjectivism) inherent in historicism and Dilthey's approach to the human sciences, and he clarified the distinctive nature of the practical participants' perspective on knowledge. Social inquiry depends on this unique interpretive access to the social world. Later thinkers, such as Hans George Gadamer, Paul Ricoeur, Charles Taylor, and Jürgen Habermas, have critically refined these insights employing a greater emphasis on mutual understanding and accountability that address lacunae in Heidegger's conception of social life.

Heidegger's conception of Dasein was a direct influence on the school of existential psychology practiced by psychologists such as Ludwig Binswanger, Viktor von Weizsacker, Eugene Minkowski, and Rollo May. Dasein analysis created by Heidegger's friend Menard Boss focused on elements of Heidegger's philosophy, such as Being-toward death, own-ness, and authenticity to analyze individual behavior. In case studies, Boss and Binswanger emphasized not the unconscious motives of the Freudian psychology but its structure as exemplified in Heidegger's conception of being human. They looked at the way the individuals take a stand or fail to take a stand on their own being.

Social scientist Bent Flyvbjerg has employed Hubert Dreyfus's reading of Heidegger to suggest an account of the case study method based on the phronetic (i.e., interpretive) insight of the social inquirer. In Flyvbjerg's conception of phronetic social science the essence of the case study method is its ability to provide insight into the typical structure of an issue or problem. The validity of insight does not depend on the use of a variety of cases from which the social inquirer can make generalizations, or in any quasi-scientific design, but from an authentic insight into the nature of a constellation that might be gleaned from a single case. It provides understanding rather than prediction. Insight, however, is more a matter of the virtuoso skill of the inquirer, the experience and judgment to recognize patterns. It is a matter of phronesis, that is, the practice knowledge of a participant who learns to grasp patterns of life from the inside. Like Alastair MacIntyre, Flyvbjerg's approach

differs from comparative case studies. Here, cases are compared and contrasted in order to extract elements common to the phenomena under study.

Other scholars influenced by phronetic social science have extended the use of authentic or committed social science in the direction of *participatory action research*. Here, much like in participant observation, the inquirer is involved in the group under study so that he or she can understand the meaningful activities of the social group from the members' own perspective. Although the participant observer may still maintain a certain social distance from the group, participatory action research involves a commitment by the inquirer to a project in which she is often an advocate. This yields knowledge not only of the reasons and meanings employed by others but also a strong form of committed knowledge that grasps the strategies and tactics of power employed by actors in a situation from the inside.

### Critical Summary

Heidegger's notion of Dasein has been criticized for its inadequate account of responsibility. Critics feel that authentic choice for Heidegger is more a matter of pure decision than of a genuine critical consciousness.

## DATA RESOURCES

---

Data resources provide evidence for case study research. Conducting a case study involves gathering an extensive array of data resources related to the central phenomenon under investigation, that is, accumulating evidence about the case. Data resources may include documentation, archival records, artifacts, interactions, or direct observations; all can become evidence in case study research. The various data resources are woven together into a coherent description, exploration, or explanation of the case.

### Conceptual Overview and Discussion

#### *Varied Types of Data Resources*

As a research tradition, case study research can involve an eclectic mix of research methods and data resources. One single kind or source of evidence is typically insufficient to sustain a case study; instead, multiple sources of evidence are generally considered essential because of the need for extended descriptions to understand a given case. Multiple data resources provide a description of the case from different angles and perspectives and allow researchers to address possible discrepancies or inaccuracies that could result from a single data resource.

Case studies tend to focus on cases as they occur in natural, real-world settings. To understand such settings it is common to review documents, artifacts,

and archival records that have accumulated before and during the case study research period. These data resources might include policy statements, guidelines, reports, letters, memos, meeting minutes, account books, school records, site blueprints and layouts, Web pages, brochures, posters, work products, and so forth. Researchers may consider textual and visual aspects of these resources. In addition, researchers may seek written evidence from participants in the form of questionnaires, journals, stories, sketches, and other such materials.

Interviews are another common interactive method of gathering data for case study research. These interviews could be formal or informal, structured or unstructured, and individual or collective (e.g., focus groups). Interview records might be documented in audio or video recordings, field notes, or transcripts. Interviews could be conducted with individuals who are the focus for the case or with individuals who help to elucidate the case without being the focus of that case (e.g., a case study of a child with special needs might involve interviews with the child her- or himself or interviews with any combination of parents, siblings, teachers, and other individuals who could help the researcher understand the child).

Direct observations for a case study tend to be recorded on site in field notes (which may include textual data, sketches, and maps) and checklists, but they could also be drawn from audio or video recordings or photographs. As well, some researchers rely on trace data captured by software and computer logs, wear patterns left behind in a site, and similar evidence.

It is not always possible to predict in advance what data resources will be most useful or informative for a case study; therefore, case study researchers tend to begin their studies with a broad focus on accumulating any available evidence. Some researchers might characterize the early phases of case study research as a brainstorming approach whereby they consider all kinds of data resources without prescreening, judging, or limiting options. As the study takes shape, researchers become more conscious of the desirable foci for the case study and the relevance of potential data resources.

In collective or comparative case study research, researchers need to be conscious of the comparability of the data across cases. Direct comparisons may be

easier if similar data resources are considered for each individual case study. However, similar data resources may not be available or appropriate for each individual case study, so researchers may consciously choose to consider dissimilar data resources across the individual cases within comparative or collective case study research.

### Application

Case study reports typically include a detailed description of the data resources used as evidence to inform the work. Some sample studies can provide illustrations.

One example is the research of Marjorie Padula and Dana Miller, who conducted a collective case study of four mothers who returned to school to pursue doctoral studies full time. Data resources for the case study included interviews, direct observations, and documents, with comparable information gathered from and about each mother. Interview data resources included an initial semi-structured interview with each mother, field notes recorded during the interviews, a follow-up interview with each mother, and verbatim transcripts of each interview. Field notes from direct observations were recorded in formal classroom settings and in informal interactions during meals and other activities. Documents included graduate school applications and personal goal statements. Padula and Miller considered all interview transcripts and field notes, observational field notes, and documents during data analysis. The interview transcripts and field notes became the primary data resource for the case reports, and the observational field notes and documents provided contextual detail and corroborating evidence.

In other research, Michelle McGinn and David Boote conducted a case study of problem solving in a History of Mathematics course. The main data resource for the case study was a series of videotapes of joint problem-solving sessions that lasted from 1 to 2 hours. Supplementary data resources included partial transcripts from the videotapes, rough notes made by the problem solvers as they worked on the homework, the final submitted homework assignments (including the teaching assistant's feedback), field notes taken during lectures and tutorials associated with the course, the course textbook, and interviews with other

students and with the instructional team (a professor, a teaching assistant, and a frequent guest lecturer).

McGinn compared this case study of problem solving with two other case studies of problem solving conducted by individuals trained in mathematics and science. The other two cases involved problem solving by a design team in a software engineering firm and problem solving in a statistical consulting service where graduate students served as interns working under the supervision of a senior consultant. Whereas the main data resource for the case of problem solving in the mathematics course was the set of videotaped homework sessions, the main data resource for the other two case studies were observational field notes recorded as the researcher shadowed a lead team member engaged in collaborative problem solving. The data resources were selected specifically for each case study, with considerable divergence across the three case studies, yet despite these differences the three cases have sufficient similarity to allow productive comparisons.

### Critical Summary

Case study research can draw from a range of historical and contemporary data resources. Researchers need to consciously consider multiple data resources, especially those that may contradict or complicate emerging understandings about a case. The extent and variety of data resources contribute to the quality and depth of the case study, whether it is an individual case study, a collective case study, or a comparative case study.

## DECENTERING TEXTS

---

The decentering of texts is a project of critical deconstruction of that which appears as text. It is the process of examining and analyzing a text from a place of otherness, marginalization, or decenteredness, in order to make visible or to reveal those frameworks or mainstream structures of influence that are the “center” of mainstream society.

### Conceptual Overview and Discussion

*Decentering* is the process of rejecting a center, a privileged reference, or an absolute archia. Decentering is consistent with the rejection of the usefulness of mega-theories or all-encompassing descriptions of social processes and thus challenges sociology's desire to secure a fully centered human subject comfortably situated in a world of roles, statuses, norms, values, and structured social systems. This rejection was characterized by Jacques Derrida as the rupture in the history of structure that occurred in the late 19th and early 20th centuries, heralded by Friedrich Nietzsche's destruction of all axiological–ontological systems as well as Martin Heidegger's destruction of traditional metaphysics and ontotheology.

What is included in the concept of “text” being decentered includes the broadest use of the term possible. It may apply to any representation. This would include a written work, such as a book or poem; words of a song; written music; a film; or an e-mail conversation. Some scholars use paintings and pictures as texts that they analyze.

Implicitly assumed in this methodology is that meaning and meaning-making occur through expression in symbols or written text. Nothing is ever outside of a text or not capable of being represented by language. Decentering texts builds on Ferdinand de Saussure's structuralist theory of language. Challenged is the idea that readers, writers, and speakers occupy concrete places where thoughts, intentions, and meanings are organized in logical sequential and linear order clearly understandable to the listener or reader in a oneness of central meaning. It is the position of the decentering scholar that meaning-making of the speaker or writer is structured by language that does not permit all of the parties to the communication (whether it be speaker, writer, or listener or reader) to have full access to the meaning. Everyone has a subjective experience of articulation or, in other words, constructs the text differently. Thus, there is no center of meaning contained in a text.

It is in the process of decentering that various “-centrisms,” such as ethnocentrism, anthropocentrism, phallogentrism, egocentrism, theocentrism, and logocentrism, are revealed. Rooted in post-structuralist theory, the methodology of decentering texts posits that texts need to be understood in their historical, political, and cultural places and times. Their author was working and experiencing meaning-making in a particular historical place and time that would have affected that author's meaning-making.

To *decenter* a text is to unsettle or make visible the familiar philosophical and political frameworks or mainstream notions of experience, human rights, white antiracism, human progress, scientific progress, modernity, the unity of scientific method, the desirability of universal knowledge claims, and other ideas central to philosophy. It is to take a perspective from elsewhere to reveal the frameworks that structure our thoughts and actions “here.”

Decentering text is important, because the various centrismes are usually not maliciously motivated through prejudices of individuals by means of false beliefs and bad attitudes but through institutional, societal, and civilizational or philosophic forms of centrismes that are embedded and naturalized so as to often be assumed or not questioned. These forms are often the least visible in day-to-day life. Because of this, these centrismes have the most powerful effect on individuals. Decentering

text is a method of exposing and therefore questioning these dominant, often hegemonic, forms.

Decentering is used in feminist theorizing, standpoint, or phenomenology exercise. It is postpositivist.

The result of decentering is the creation of a dialogue to explore how multicultural global postcolonial institutions, cultures, and practices create opportunities to raise new questions, engage new dialogues and discussions on new topics and new conversational partners, and organize different kinds of social relations that might be likely or perhaps even possible. In this way, through the process of dialogue, decentering is an emancipatory social project promoting positive social structural change to decenter mainstream, white, middle-class patriarchal-dominant discourse and to empower marginalized “other” discourse.

### Application

The methodology of decentering texts is used by a wide variety of sociology scholars. Examples from a variety of approaches have been chosen that comprise a list that is by no means exhaustive. These examples were chosen for the variety of places of “otherness” or decenter and the medium of texts used.

Uma Narayan and Sandra Harding compiled an edited text of decentering works in *Decentering the Center: Philosophy for a Multicultural, Postcolonial, and Feminist World*. This book comprises works of many authors focusing on feminism, cultural identity, development, and indigenous people. It is a good starting point for a large variety of scholarly work and case studies in this area.

An example of decentering film is Norman Denzin’s deconstruction of the film *The Morning After*. In this work he shows how postmodern texts are frequently organized under the rubric of the classic morality tale. A subject is taken through the three steps of seduction, corruption, and redemption to illustrate how corrupt, unethical society has lost sight of traditional moral principles and values. Denzin used this film to illustrate how postmodern film resorts to the fictional morality of “one evil” or the traditional family setting underlying the postmodern society. Denzin deconstructed *The Morning After* to illustrate the patriarchal bias attached to the circumstances and situations of age, gender, class, race, and ethnicity. In this way

the embedded meanings of these identities are decentered from the biased lens of the white, middle-class, patriarchal perspective that perpetuates race, ethnicity, and gender stratification within the postmodern society.

Silvio Gaggi published a book of case studies on decentering the subject entitled *From Text to Hypertext: Decentering the Subject in Fiction, Film, the Visual Arts, and Electronic Media*. Through an examination of selected examples of visual art, literature, film, and electronic media he deconstructed and constructed the subject. Included is a consideration of electronic media and works of fiction in which readers themselves become decentered. The focus is on the subject or topic as the center. *Subject* is widely defined as that which is formed by language and representation as a construct that can be deconstructed. Through several chapters Gaggi covers visual representations in paintings and photography, beginning with Renaissance works, suggesting a coherent unified subject to modern and postmodern works that challenges this unified conception of subject. Several chapters use both literary examples and film that imply a fixed subject. However, through careful deconstruction, the author suggests elusiveness, flux, and transformation. Finally, new means of representation and communication, or *hypertext*, is considered. This is the most significant contribution of this work in that it considers the modern form of electronic communication and text.

Hypertexts are textual networks (or segments of text electronically linked to a network) organized around a work or theme in which the reader has freedom of movement within that network. These texts subvert the sense of a primary text or a center with a defined beginning, a dominant axis of movement, and a clear end. Hypertext emphasizes that the marginal has as much to offer as does the central and redefines the central by refusing to grant centrality to anything, to any lexia, for more than the time a gaze rests upon it.

An interesting example of decentering was undertaken by Elaine Power in the examination of the visual method of film, video, and photography in relation to food in her work, “De Centering the Text: Exploring the Potential for Visual Methods in the Sociology of Food.” The image is argued to have become more powerful than the word and, more than ever, social agents and social researchers

know more than can be expressed in words. By examining these texts, sensual, nonrational, and material aspects of life can be uncovered. Food and the tactic processes of its preparation and consumption are well suited for this method of study. Three methods of gathering visual research discussed are (1) collaborating with research participants to produce visual images, (2) producing visual images, and (3) examining preexisting images.

### Critical Summary

Decentering may result in the creation of sharp binaries about qualities, abilities, or locations of men, women, cultures, constructs, gender, or cultural identity that shapes the self-understanding and subjectivity of people who inhabit spaces. It may result in “essentialism” and reductionism by the comparison of a center to another decentered space and through this exercise the omission of many other multiple spaces.

Furthermore, through this process a seriously distorted representation of “others” or decentered spaces may occur. For instance, the depiction of Aboriginal people or third world people runs a risk of overgeneralization, creating or furthering stereotypes of these marginalized groups and seriously distorting their space if done in well-intentioned but misinformed manners.

## DECISION MAKING UNDER UNCERTAINTY

---

In decision making under uncertainty one studies how the single case (the decision maker, e.g., a radiologist) chooses between alternatives (e.g., presence or absence of a tumor on an X-ray) when the information presented is uncertain or incomplete. By evaluating two possible types of errors that the decision maker can make, false positives and false negatives, estimates of two independent characteristics of the decision maker are obtained. One characteristic is the decision maker's *sensitivity*, which is his or her ability to detect the presence of the “signal” (e.g., tumor). The second is the decision maker's *response bias*, which is his or her tendency to favor one of the possible alternatives (e.g., a higher willingness to err on the side of caution). In decision contexts where the two types of errors have differential payoffs or costs, or where the two alternatives are not equally likely to occur, the decision maker's decision process can be evaluated in more detail with the *receiver operating characteristics (ROC) curve* (also called the *relative operating characteristics curve*). Assessing these separate characteristics of the decision maker provides a more informative alternative to simply assessing his or her accuracy rate (e.g., overall percentage-correct decisions) and is one way of studying a single case, an individual, who is in the process of making a binary decision.

### Conceptual Overview and Discussion

The simplest decision-making situation is when a decision maker must choose between two possible alternatives (e.g., disease or no disease). To assess the decision maker's sensitivity and response bias, the researcher uses two types of errors that the decision maker can make: a *false alarm* (false positive, or Type I error in statistical hypothesis testing) and a *miss* (false negative, or Type II error). Data for the estimates of these two probabilities are the relative frequencies of the decision maker's responses to each of the two alternative scenarios over repeated trials. Table 1 shows the possible situations that may arise. The stimulus presented to the decision maker is one of two, either containing a signal or not. The decision

**Table 1** Four possible outcomes in a two-choice decision task

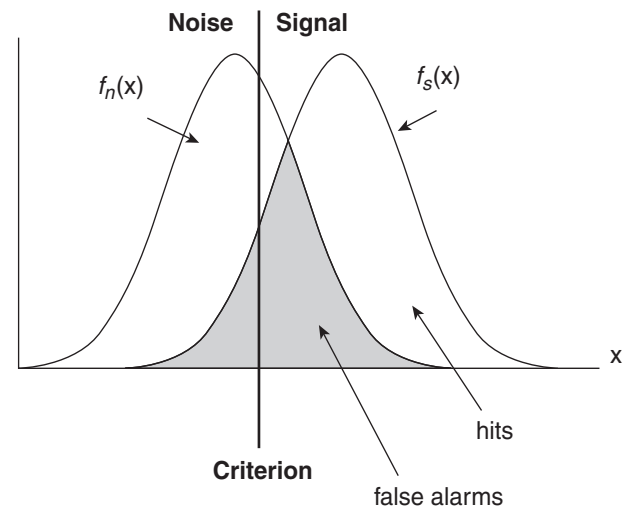

Stimulus presented	Response made	
	Noise	Signal
No signal	Correct rejection .60	False alarm .40
Signal	Miss .15	Hit .85

Note: Numbers are example values used in the text for a numerical example.

maker can make one of two responses, either signal present or not. This creates four possible outcomes, but note that because for a given stimulus the decision maker must give one of the two responses the probabilities within each row must add up to 1.0.

#### Theoretical Basis: Signal Detection Theory

The theoretical basis for obtaining estimates of the decision maker's sensitivity and response bias is known as *signal detection theory* (SDT). SDT was developed and introduced into psychological research in the 1950s and is a direct application of statistical hypothesis testing to the tasks of detecting "signals" in noisy stimuli and of discriminating between two confusable stimuli. As in statistical hypothesis testing, there are two distributions, the noise-alone (analogous to the null) distribution and the signal + noise (alternative) distribution (see Figure 1). In SDT, the two distributions represent the probabilities of the various strength of evidence that the decision maker has for each of the two possible situations. The two distributions overlap, and there is one point, the *decision criterion*, along the evidence-strength axis that represents the decision maker's critical decision point for his or her *decision rule*. The rule applies on each trial and is stated thus: If the evidence received is stronger than the decision criterion, then respond "signal"; if the evidence is weaker, then respond "noise." The evidence, however, can come from either of the two situations. So, if the strength of evidence falls above the criterion but was from the noise stimulus,  $f_n$  distribution, then the decision maker

**Figure 1** Probability distributions representing the strength of evidence for each of two stimuli; the criterion demarcates the four areas under these curves that correspond to the four proportions in Table 1

has made an error of the false positive type (a false alarm). Alternatively, if it had in fact been from the signal distribution,  $f_s$ , then the decision maker's response was correct and is referred to as a *hit*. The areas under the two curves to the right of the criterion are estimated by the proportions of  $P(\text{hit})$  and  $P(\text{false alarm})$  in Table 1.

Different assumptions can be made about the shapes of these distributions in SDT. The most common assumptions are that both distributions are normal with the same variances (equal to 1.0). In many, though certainly not all, empirical settings these assumptions are reasonable and empirically supported. It is also assumed, without any loss of generality, that the noise-alone distribution is centered (has its mean) at zero. Finally, regarding the decision criterion, it is assumed that its placement is under the decision maker's control and does not change over the course of the experiment (unless it is deliberately manipulated by the researcher—see more in "ROC Curves" section).

#### Estimating a Decision Maker's Sensitivity

The classic measure of the decision maker's sensitivity is  $d'$ . Under the assumptions that the distributions are normal with equal variances,  $d'$  is defined as the difference in the  $z$  transforms of

the proportion of hits,  $p(\text{hit})$ , and of false alarms,  $p(\text{fa})$ :

$$d' = z(\text{hit}) - z(\text{fa}).$$

Here,  $z(\text{hit})$  is the  $z$  value corresponding to the probability  $p(\text{hit})$  in the upper tail of the standard normal distribution; similarly,  $z(\text{fa})$  is the  $z$  value for  $p(\text{fa})$ . Using the example proportions in Table 1,  $z(\text{hit})$  is the  $z$  value corresponding to a probability of 0.85 under the standard normal curve, which is 1.04; similarly,  $z(\text{fa})$  is the  $z$  value for 0.40, which is  $-0.25$ . So, for this example,  $d' = 1.04 - (-0.25) = 1.29$ . If the two distributions overlap completely, the decision maker cannot discriminate between the two stimuli, and  $d'$  is zero. To the extent that the two distributions are separated, the two stimuli are very distinct, and  $d'$  will be large. It is also informative to note that the decision criterion point is simply estimated by  $z(\text{fa})$ , or 0.25 in the numerical example, if the mean of the noise distribution is (arbitrarily) placed at zero.

#### *Estimating a Decision Maker's Response "Bias"*

An unbiased decision maker does not favor one response over the other. In this case, the frequencies of the two types of errors (i.e., false alarms and misses) are equal, and this occurs at the point along the strength-of-evidence axis where the two distributions cross each other. Conversely, to the extent that the decision maker's two error rates differ, response bias is indicated.

To quantify the amount of a decision maker's response bias, two measures have been introduced, and both are related to the criterion point of the decision maker's decision rule. One measure,  $c$ , is simply the distance of the decision criterion to the cross-over point where  $c$  is set to zero for the unbiased decision maker. For distributions with equal variances, this cross-over point is estimated by  $d'/2$  (e.g., at  $1.29 / 2 = 0.65$ ), so with  $z(\text{fa}) = 0.40$  the response bias  $c$  is  $0.65 - 0.40 = -0.25$ . A negative  $c$  value occurring to the left of the cross-over point indicates that the decision maker favors the "signal" response. This is often referred to as a *liberal bias*. A positive  $c$  value indicates a *conservative bias*.

The second response bias measure is defined in terms of the ratio of probabilities of making the "signal" response relative to the "noise" responses (this is called the *likelihood ratio* and is symbolized

by  $\beta$ ) at the criterion point of the decision maker's decision rule:

$$\beta = f_s(\text{criterion}) / f_n(\text{criterion}),$$

and it can be easily estimated by

$$p(\text{hit})[1 - p(\text{hit})] / p(\text{fa})[1 - p(\text{fa})].$$

In the numerical example used here, this ratio is  $(.85)(.15) / (.4)(.6) = .53$ . Equal probabilities of making each type of error that is characteristic of an unbiased decision maker will give a  $\beta$  value equal to 1. A  $\beta$  value greater than 1 indicates that  $f_s$  is greater than  $f_n$  at the criterion point and thus that the decision maker has a preference for "noise" responses and a conservative bias, whereas a  $\beta$  value smaller than 1 (but always remaining positive) indicates a preference for responding "signal" and a liberal bias.

#### *ROC Curves*

The decision process in this simple choice task can be evaluated in more detail by the ROC curve. Empirical observations have found that the decision criterion can change for the decision maker across different decision contexts, even with the same stimuli. For example, if two stimuli have different relative frequencies of occurrence (referred to as *base rates*), the decision maker can shift his or her decision criterion to favor the more frequently presented stimulus. Also, if one type of error is more costly than the other—for example, to miss a tumor on an X-ray is more serious than to make a false alarm—the decision maker is wise to shift her or his criterion to reflect these differential costs.

The ROC curve summarizes the decision maker's decision process by plotting the probability of hits as a function of the probability of false alarms across a series of varying, experimentally manipulated decision contexts (base rates or costs/payoffs) for the same pair of stimuli. (It should be added that another way of obtaining an ROC curve, without manipulating the decision context, is to ask the decision maker to make a confidence rating about each decision on a simple confidence rating scale; this produces two or more pairs of hit and false alarm probabilities that are required to plot the ROC "curve.") The ROC curve thus appears in a *unit square* (from 0.0 to 1.0 on both axes). Most typically it is a concave function (with a negatively

accelerated slope) in the triangular area above the zero-to-one positive diagonal which itself represents chance performance (50–50 accuracy on both stimuli). The curve is more concave if the decision maker's sensitivity (the separation of the two overlapping distributions) is large, and it is symmetric around the negative diagonal if the variances of the two distributions are equal. Analyses of the ROC curve (e.g., converting to  $z$  plots and examining the linearity, slope, and intercept) allow for some additional characteristics of the decision maker to be illuminated; for example, one can empirically assess the relative variability in the amount of "evidence" contained in each of the two stimuli (i.e., assess the equal variances assumption).

#### *Variations on the Classic Sensitivity and Response Bias Measures and Some Related Measures of Decision-Making Accuracy*

Other measures of sensitivity and response bias have been proposed. Some of the most common alternatives are sometimes called *nonparametric* because they are based on the ROC curve and make no distributional assumptions. For example, sensitivity can be measured by  $A'$  (area under the ROC curve) or  $d'_e$  (intersection of the ROC curve with the negative diagonal). A nonparametric response bias measure is  $B'_{HP}$ , which William Donaldson improved and introduced as the  $B'_D$  measure. Donaldson also reviewed and compared some of the other nonparametric measures and provided a historical overview of the development of this approach.

Two other measures of a decision maker's performance that are related to his or her general accuracy are (1) the *positive predictive value*, which is the ratio of hits (true positives) relative to all signal responses made by the decision maker (hits plus false alarms) and (2) *sensitivity*, defined here as the proportion of hits out of all trials with the signal presented (i.e., hits plus misses), a measure that is analogous to statistical power in statistical hypothesis testing.

#### **Application**

John Swets, one of the original developers of SDT and its applications in psychology, has collected a wide range of examples in which SDT and ROC analysis has been used, including areas in clinical radiology, information retrieval, weather forecasting,

polygraph lie detection, aptitude testing, survey research, and automated warning systems. Within psychology, SDT has been used frequently in psychophysics and perception (auditory, visual, pain) and for studying memory in cognitive psychology. In the area of recognition memory, for example, a research participant is shown a list of items (typically words) and then at some later time is asked whether he or she has seen the items as they are presented again, this time mixed with previously unseen items. The "old," previously presented items are analogous to the signal stimuli, and the "new" items are the noise stimuli. The person's recognition memory is then analyzed for his or her ability to recognize old items in light of his or her response bias tendencies, typically across different experimental conditions of particular interest to the memory researcher (e.g., varying the list lengths, the time intervals that the items need to be remembered, different categories of items). Several researchers have formally studied recognition memory with this approach, taking it in several directions. John Wixted discussed the more recent developments in his 2007 article.

Applications in several other fields have also been suggested. For example, W. Wade Martin and Marta Rovira suggested how SDT can be used in social psychology and offered several examples. SDT has also been extended to situations in which the decision maker must discriminate among three or more alternatives varying along one dimension (e.g., loudness of tones) and to discrimination among stimuli that differ along multiple dimensions (e.g., both loudness and pitch of tones).

#### **Critical Summary**

The use of SDT and its measures of sensitivity and response bias offer a rigorous, theoretically based approach to case study. The method of analysis provides an enhanced description of the decision maker when the decision or judgment must be based on uncertain or incomplete information, by providing insight into two components of the decision process: the decision maker's ability to distinguish between the two choices versus his or her tendency to respond in a biased way. It is a simple and versatile method and can be applied in a wide variety of settings. In addition to using it for studying the detection accuracy of a decision maker,

it is readily adaptable to studies in which two (or more) confusable stimuli need to be discriminated or identified.

Because the sensitivity and response bias measures, as well as the ROC curve, are all based on proportions (of hits and false alarms), it is important to collect enough data to obtain reliable and stable estimates of these proportions (typically no fewer than 25 trials with each stimulus, preferably 100 or more trials per stimulus). This is typically not an obstacle, however. Furthermore, although estimates are obtained for a single decision maker, once obtained they can be used to make comparisons across decision makers, or they may be combined into group analyses for comparisons across experimental conditions.

that we use in our studies by uncovering their factual nature. The term *deconstruction* refers to the search for new meanings, thoughts, and perspectives. Indeed, the vast majority of case studies are constructed around various types of narratives that are plotted around oppositions, including change/resistance to change, organization/dysfunctions, and so on, and with characters behaving according to their pure roles, such as manager/employee, teacher/learner, and so on. Deconstruction is the dismantling of this conceptual arrangement by way of welcoming alternative insights that challenge the presuppositions of a given text's creation.

### Conceptual Overview and Discussion

The term *deconstruction* was theorized by the French philosopher Jacques Derrida. The term has had wide-ranging philosophical implications; this entry emphasizes its implications for case study research. Although Derrida never explicitly formulated a definitive definition of deconstruction (which would be contrary to his approach), he acknowledged four phrases that highlight its various facets.

The first of these phrases is referred to as “deconstruction is America.” Derrida's deconstruction was first debated in North American universities. In its early years, it was used as a method for literary criticism. Deconstruction does indeed apply to texts, but articles, theories, discourses, case studies, accounts, and even practices, as well as decisions, can be considered as texts. As a literary method, a deconstructive analysis first looks for the binary oppositions that organize a given text (e.g., communication/noise, change/resistance to change). It then underlines how the first term in the binary opposition is considered as positive whereas the second is devalued and parasitic to the first. Yet a close scrutiny to both concepts making up the binary opposition would reveal that each is in fact contaminated by the other. The deconstructive analysis implies that both terms embody and thus imply the other. The binary opposition appears to be too simple to grasp the studied phenomenon. A deconstructive analysis can also involve a search for what is not stated in the text, such as what may be presumed by the text. If such presuppositions are rendered

---

## DECONSTRUCTION

---

Deconstruction enables an active questioning of the foundational concepts and representations

explicit, the text is thus repainted with another meaning. Other approaches become possible. The perspectives, the plots, the frames, the fringes are open to be rebuilt; new insights and vocabularies are required to retell the story.

The second phrase acknowledges that “deconstruction means speaking more than one language.” Although unaware, we always draw on the same language to speak of a phenomenon; this means we use the same words, variables, metaphors, logics, and so on. Drawing on other languages to organize our theories would open the way for new insights. Here a case study, with its rich and thick descriptions, as well as its prescription for multiple sources of evidence, can be of much help. As a result, the deconstructionist looks closely at and pays special attention to phrases uttered by usually silenced individuals, including frontline workers, people with learning disabilities, unemployed people, and elderly residents. She may even try to voice their accounts, through lending them her voice, thus enabling them to speak through her. Through careful listening of previously silenced individuals, the deconstructionist strives to disrupt her own former insights. By taking seriously the words and worlds of the previously silenced, the deconstructionist seeks to build or craft an alternative language to speak of a given phenomenon. Because she is cautious about processes in which privileging occurs, the deconstructionist does not situate her language as superior but does emphasize the need for multivocality and multiple languages.

Derrida’s third phrase is “deconstruction is what is happening, to have something to happen.” Contrary to oft-cited criticisms of deconstruction, deconstruction does not imply destruction. Deconstruction is less about knocking down a concept or a text than about affirming something different, about enabling the arising of new thoughts. By highlighting various frames and tracks that have previously acted in constraining our thoughts, concepts, discourses, and practices, deconstruction calls for more demanding and more promising ones and proposes new conceptions to the academic arena.

The fourth and last phrase acknowledged by Derrida is “deconstruction is the impossible.” Deconstruction does not look for the one conception that would rule out all the others; it does not

seek out the one best language. *Deconstruction* refers to a constant striving for an inaccessible alternative. This is the quest for the impossible, for what will never definitively be grasped, that which puts thought into motion. For example, decisions may once have been thought to be encapsulated into the decision theory framework. Other frameworks were then proposed that criticized the first and added social, organizational, or political explanations. Derrida would argue that no such decision framework can grasp the concept of decision because for a decision to be considered a pure decision would imply a break from any framework. A pure decision sets itself out of the course of any given story. Of course, this kind of decision would at first seem to be impossible. But this impossible is what thought and action are striving for. This insight underlines the limits of all the other frameworks.

Alongside deconstruction and of much interest for case study research is Derrida’s questioning of authorship (intertextuality and iterability), the organization of texts (decentering texts), the central place given to speech (logocentrism), and his criticism of phenomenology (difference).

### Application

Case study research can draw on deconstructive analysis in various ways. The most common way is to use the case study as providing the text for deconstruction. Examples include studies that have deconstructed charismatic management; organizational culture; company official texts; a maternity leave policy; business ethics; or management devices such as total quality management, human resource management, and so on.

Another manner of using deconstructive analysis in case study research is to draw on a case study for the constructive and affirmative facet of the deconstruction. For example, after having uncovered the foundations and questioned concepts such as decision making, corporate social responsibility, tacit knowledge, or evidence-based medicine, one can use a case study to search for and develop alternative languages that will aid in discussing or proposing new insights on the subject.

Finally, deconstruction may be one among other strategies used in a case study. For example,

in their in-depth study of a laboratory, Bruno Latour and Steve Woolgar deconstruct the opposition between the original and the copy alongside many other moves.

David M. Boje gives an example of the deconstructing strategies by applying them to the grand narrative of Marxism. He first notes that the discourse is based on a binary opposition between capital and labor and documents how the first is said to dominate the other. He then tells the other side of the story, finding several examples and processes in which labor dominates capital. He does not oppose the Marxist labor process theory but shows how the overall plot (the greedy accumulation of capital deskills the workers in order to capture always more of their surpluses) does not grasp the whole story. We need to see it from several angles, listening to many voices. He ends up with a far more complex story, in which both capital and labor haunt each other, and in which each agent has multiple selves and agency.

Another example is Jean-Luc Moriceau's "Faceless Figures: Is a Socially Responsible Decision Possible?" In this study he deconstructs the concept of corporate social responsibility. The analysis reveals that the concept of corporate social responsibility appears far less pure than initially presupposed: Despite its claims, the social dimension is shown as being contaminated by the economical calculus, the corporate level as shielding the decision makers, the actual beneficiaries as being replaced by mere figures of stakeholders. The absence of faces is also remarked on. This study thus proposes a look at the institutionalization of corporate social responsibility, in its transformation from initially being an ethical concern to a focus on organizations striving to achieve good scores from rating agencies. The previously marginalized inscription of responsibility into scores comes to assume a central importance. This reversal of hierarchy suggests a new insight into the practices and discourses of corporate social responsibility while putting to the front the adversary concept of the faceless figure.

### Critical Summary

Deconstruction is a very powerful strategy that seeks to propose new insights, especially on issues that have been already documented, through

exposing the taken-for-granted. A case study may be a useful companion to deconstruction for grounding and illustrating often-abstract and implicit argumentations. Although deconstruction is often critiqued for offering mere criticism, a successful deconstructive analysis will offer a new panorama of insights into an existing text or practice. A study that would end up with a very common and straightforward critique could not claim to be deconstructionist.

Derrida's philosophical concepts as well as his numerous books require a close and are a challenging read. Deconstructionists' case studies are likely to be accepted in critique journals rather than mainstream journals.

## DEDUCTIVE–NOMOLOGICAL MODEL OF EXPLANATION

---

The deductive–nomological model is a widely accepted account of the nature of scientific explanation. It is

often called the *covering law model* (CLM), or the *Hempel–Oppenheim model*. In an explanation under the deductive–nomological model, the *explicandum* is some phenomenon requiring explanation. The *explicans* of the *explicandum* removes the puzzling or problematic character of the *explicandum* by showing the phenomenon to be a particular case of a known general law. In other words, according to the CLM, explanation orders experience by bringing particular instances under general principles. The more particular instances can be brought under a more general principle, the better the explanation. Explanation progresses from the less general to the more general.

In a CLM explanation, the *explicandum* follows logically from the *explicans*. If, for example, a pencil is dropped and falls, the explanation, according to the CLM, is as follows:

Explicandum: Observation: Pencil falls.  
 Explicans: Initial conditions: Pencil dropped.  
 Law(s): Law of Gravity

The falling of the pencil is thus explained by being subsumed under the Law of Gravity.

### Criticism

This model of explanation has, from early on, been subjected to serious criticisms by both philosophers of science and social scientists. According to physicist and philosopher of science Norman Campbell, the belief that it is the aim of science to bring all particular instances under one extremely general and universal law neglects the most important part of science and fails completely to understand its aims and development. Even if this were possible, Campbell notes, the resulting explanation would not be what science, developing the tendencies of common sense, demands. Sociologist Phillip Gorski observes that the model is inadequate considering that sociology has not as yet produced any such laws, and political scientist Samuel H. Beer asserts that the model has not led to success and that attempting to follow it would stand in the way of any social scientist who took it seriously.

### Curious Status in the Social Sciences

The CLM enjoys a curious status in the social sciences. On the one hand, it is still widely believed to

be a correct account of what a scientific explanation should be like. It continues to be widely presented as such in the social science methodology textbook literature. On the other hand, few if any explanations in the social sciences come close to fitting the model. This view of explanation would appear to be particularly distant from case study research, with its focus on complex situations. Even those social scientists who subscribe to the CLM usually admit that there are, as yet, no universal laws in the social sciences or that there are only a few that might arguably qualify as such. Duverger's Law and Michels's Iron Law of Oligarchy are among those that might be nominated. Yet even they are not universal laws in the sense of the CLM. Few would argue that the deductive–nomological model characterizes the explanations extant in the social sciences.

Some social scientists—for example, Robert Merton—argue that the absence of universal laws in the social sciences is due to the fact that they are not yet mature sciences. When they have reached maturity, so it is implied, their explanations will conform to the CLM. In the meantime, it is acceptable for social scientists to make use of what Merton calls “theories of the middle range.” Yet, as Gorski points out, such generalizations are not the universal laws presupposed under the CLM. In recent years, several writers have drawn attention to another problematic aspect of the deductive–nomological model, namely, that it mistakenly assumes covariance or regularity implies causality.

### Popper's Account of Deductive Explanation

Karl Popper's account of deductive explanation is sometimes mistakenly identified with the CLM, which is sometimes referred to as the *Popper–Hempel model*. Like the CLM, in Popper's account of a scientific explanation the *explicans* of the *explicandum* consists of laws and initial conditions, and the *explicandum* must follow logically from the *explicans*. However, although this is a necessary condition for Popper it is not a sufficient condition. First of all, Popper agrees with those critics of the CLM who point out that correlation or covariance does not entail causation. Something must drive the explanation, must account for *why* the *explicandum* necessarily follows from the *explicans*. An *explicans* may eliminate the problematic character

of a phenomenon in various ways. Subsuming the phenomenon under a general law, as prescribed by the CLM, is one possibility. However, even in such cases the cause of an observed regularity may be unknown and requiring explanation. Moreover, the problematic character of a phenomenon may also be removed by repairing or filling out initial conditions, or by reconceptualizing the situation. In any case, according to Popper, the *explicans* must be rich in content and must have a variety of independently testable consequences, which are different from the *explicandum*. Popper's account of deductive explanation is thus, unlike the CLM, congenial to case study research. It is precisely through correction or reconceptualization of the situation (initial conditions) that explanation is provided of why a particular case deviates from what had been expected.

## DEPTH OF DATA

---

*Depth of data* refers to the detail, richness, comprehensiveness, and explanative power of the data

supporting a case study. Increased depth of data positively affects the perceived credibility and applicability (or generalizability) of a case study. At the same time, this increased depth can also raise ethical challenges regarding the protection of privacy and confidentiality.

### Conceptual Overview and Discussion

#### *Depth and Breadth of Data*

Characteristically, case study research draws from an extensive and varied array of data resources to bring depth of understanding about a well-defined, narrowly focused, and clearly bounded case. Researchers may face a trade-off between depth and breadth in gathering and presenting data for a case study. Although it is essential for case study researchers to seek out extensive evidence to develop a comprehensive understanding of the case, choices must be made about how much of that evidence can be presented directly in any case study report. Researchers must consider publishers' requirements and readers' needs in judging the amount and depth of data that can be presented.

The challenges of gathering and presenting sufficient depth of data in a case study report are particularly acute for collective and comparative case study research, where there is a need to consider information from multiple cases. It is not uncommon for cross-case studies to be criticized as thin, reflecting insufficient depth about any individual case. At the same time, collective and comparative case studies are valuable because the emphasis on similarities and differences across cases can provide breadth of understanding about the phenomenon of interest that extends beyond one individual case.

#### *Depth of Data Affects Credibility and Applicability*

Case study researchers establish depth of data through triangulation and thick description, both strategies that contribute to credibility of data.

Through *triangulation*, comparing and contrasting across multiple data resources, case study researchers uncover consistencies and inconsistencies, thereby providing evidence from multiple perspectives and incorporating assessments about the veracity of the evidence presented. In this way, researchers can build robust understandings about

the case under investigation that are likely to be judged as credible.

Case study reports typically include *thick description*; that is, they go beyond mere facts and surface features of the case to include details, context, circumstances, meanings, significance, motivations, emotions, social relations, history, and other such descriptive and interpretive elements of the case. Thick description that is well supported by evidence will be perceived as credible. This level of detail brings the case to life for readers so that they are more likely to make positive judgments about the credibility of the case and its potential applicability in other contexts.

Thick description in a case study report provides extensive information that readers can use to understand the case. At the same time, this thick description provides an evidence base for readers to make comparisons with other situations and make predictions about how well the conclusions about the reported case might apply in these new situations. Without thick description, readers are left with insufficient information to understand the reported case or to apply that case to other situations, thereby substantively undermining the value of the case study.

#### *Depth of Data Affects Privacy and Confidentiality*

The depth of data that case study researchers seek in their efforts to understand a case leads to highly identifiable research records. Case study researchers need to seek permission or consent from relevant people associated with the case in order to access the extensive data required to generate understandings about the case. Beyond initial data access, researchers also need to think carefully about how to present this depth of data without sacrificing privacy and confidentiality commitments to the people associated with the case.

Dena Davis describes the paradox of writing case studies in the field of bioethics. As she indicates, the kinds of details that make case studies identifiable are frequently the very same details that make those case studies informative and worthwhile. Disguising details about age, gender, nationality, and other important biographical details to protect identities in case studies may confound key issues in the case and undermine

possibilities for readers to develop their own understandings that go beyond the author's original interpretation.

Researchers may need to consult with participants who could be identified in a case study or with stakeholders associated with the place, organization, or object under investigation to inform their choices about the appropriate balance between identifying details and confidentiality provisions in a specific case. In some situations, it may be appropriate to provide clearly identifiable information as part of the case study, as is common in journalism, oral history, public policy research, and other forms of scholarship. In other situations, it may be appropriate to forego certain statements or conclusions in case study research when those claims can be substantiated only with identifying details that would lead to risks or harms to someone associated with the case, and the potential benefits that could accrue from including those details provide insufficient justification for that level of risk or harm.

#### **Critical Summary**

Case study researchers strive for depth of data to generate substantive evidence and rich understandings about the cases they study. The depth of data in a given research study may need to be counterbalanced with the desired breadth of data, especially for comparative and collective case studies. Triangulation and thick description are two important considerations in achieving depth of data. Increased depth of data contributes to the resulting credibility of a case study and may affect its applicability (or generalizability). However, there are ethical challenges associated with increasing depth of data in case study research. Site access stipulations, research permissions, and consent processes affect researchers' access to data, and privacy and confidentiality provisions influence researchers' decisions about how to protect or divulge identifying information that contributes to the depth of data.

## DESCRIPTIVE CASE STUDY

---

A descriptive case study is one that is focused and detailed, in which propositions and questions about a phenomenon are carefully scrutinized and articulated at the outset. This articulation of what is already known about the phenomenon is called a *descriptive theory*. It helps to specify the boundaries of the case, and it contributes significantly to the rigor of the finished case study. The power and promise of a descriptive case study lie in its potential for mining for abstract interpretations of data and theory development.

### Conceptual Overview and Discussion

The main goal of the descriptive case study is to assess a sample in detail and in depth, based on an articulation of a descriptive theory. This theory must respect the depth and scope of the case under study, which is conveyed through robust propositions and questions. If a descriptive theory cannot be developed easily before a case study, then the researcher may want to consider whether the case is more of an exploratory case study.

Descriptive studies seek to reveal patterns and connections, in relation to theoretical constructs, in order to advance theory development. Some researchers refer to descriptive case studies as *intensive* or *focused* case studies; these are semantically helpful terms for directing the researcher's desired level of intellectual penetration of the phenomenon.

To some degree, from the perspective of positivist research, all types of case studies can overlap, because they have the following similar aims: (a) to

depict the relatively incontrovertible details of the people, place, events, transactions, and processes of the case—a description that others would likely make if they had been there; (b) to give a clear picture of what is happening, without making judgments—an organized and coherent presentation of the phenomenon; and (c) to develop and expand on relevant concepts. A descriptive case study distinguishes itself from other types of case studies by its preoccupation with articulating a descriptive theory. In so doing, robust concepts emerge, conflate, and expand to inform, confirm, refute, and further shape a priori theories. Most important, descriptive case studies allow the reader to see the case through the theory-driven lens of the researchers. Studies are considered to be descriptive cases if there are no analytic comparisons between groups and no attempts to make causal statements or to describe unexplored territory.

The findings from descriptive case studies are generalizable to theoretical propositions. At the same time, as with expert knowledge-makers across methodologies, descriptive case study researchers thoughtfully consider whether their findings have implications elsewhere. Teasing out such implications, in part by examining rival interpretations, helps other researchers posit better questions, inspect data more closely, entertain new possibilities, and conceive the once inconceivable.

### Application

Robert Yin, an expert on case study design, articulated the critical need to establish a protocol before data collection. Such a protocol, in the context of a descriptive case study, would include the following: an overview of the case study project (objectives, issues, topics); field procedures; case study questions clearly linked and informed by propositions from the literature and a guide for how the case will be reported (outline, format for the narrative, etc.).

Agreed-upon common sources of evidence in case studies are documents, interviews, direct observations, participant observations, and physical artifacts. Not all of these sources are relevant for all cases, because each case will present different opportunities for data collection. As discovery occurs, it is critical to use rival hypotheses and theories to enhance the robustness of the study.

Eminent case study researcher Robert Stake pointed out that case study research is largely reflective work that requires a commitment to pondering the impressions and deliberating recollections, but not necessarily following the conceptualizations of others. He noted that local, foreshadowed, and consequential meanings are all important. Ultimately, the researcher decides, through both intuitive and analytical processes, which type of meaning will be privileged and the extent to which other types of meaning will unobtrusively form the backdrop.

One example of a descriptive case study is the one conducted by John Pyecha, who effectively used descriptive theory in the form of idealized expert-developed scenarios about a hotly debated issue in special education (inclusion vs. special classes). The researchers used their idealized scenarios (generated before data collection) to match up with activities conducted by each state that ascribed to one of the two philosophies. Knowledge about the phenomenon allowed the researcher to predict patterns that were eventually confirmed through a matching of the idealized scenarios with the activities of the state. Data that did not fit under the original scenarios were still collected for later analysis. The pristine way in which the case study was formulated made for crisp boundaries for data collection, an often-troublesome challenge for case study researchers.

### Critical Summary

Making use of a robust descriptive theory enables the descriptive case study researcher to penetrate the essential understandings of the case and offer up for scrutiny a case for informing theory development, in addition to potentially providing a valuable addition to the case study databank for future researchers.

## DEVIANT CASE ANALYSIS

---

Deviant case analysis is a methodological approach that is an outcome of a researcher's sampling decisions and treatment of data. Sometimes referred to as *negative case analysis*, the approach is based on the view that any findings generated from data should be able to explain a wide range of observations. This provides both the opportunity for finding novel theoretical relationships as well as confidence that a study has been conducted in a rigorous way.

### Conceptual Overview and Discussion

The idea that deviant cases are important to carefully examine is embedded in many of the qualitative approaches that are widely used in case study research. One of the central features of grounded theory is the *constant comparative method of data analysis*, the process by which theoretical ideas are revised and redesigned as data are compared with them. In this way, data are organized and compared with the theoretical relationships contained in the data, being constantly adjusted for new data that are collected. If these new data do not conform to the theoretical relationships present in earlier data, then new relationships are developed that account for all available data. The result is a condition of *theoretical saturation*, the signal that theory has been developed using the full range of data collected. The deviant or negative case study therefore provides the opportunity for a more robust theory, one that explains the unexpected or atypical as well as it explains the expected or typical.

Choosing to include deviant cases in research is therefore a matter of sampling, something that matters to all qualitative researchers. David Silverman provides a comprehensive treatment of the decisions that go into selecting a case. He suggests that

although some researchers may be content to provide a purely descriptive account of a phenomenon with no regard for generalizability, most are not. Instead, a hallmark of good qualitative research is that it produces explanations, for example, why something happens or under what conditions it happens. These types of explanations lend themselves to discussions of generalizability, usually couched in terms of transferability of findings or resonance of findings in contexts other than the one researched. As such, there is an issue of representativeness embedded in all qualitative or case study research that sampling can, to a certain extent, address.

### Application

Sampling in qualitative research is typically explained in theoretical or purposive terms; in other words, what should determine the choice to study a particular case or set of respondents? *Purposive sampling* is guided by the desire to have a case illustrate phenomena of interest. This requires careful thought on the part of the researcher to determine the people from whom and places where useful data can be obtained. When these decisions are theoretically determined, the term *theoretical sampling* is used. It is primarily concerned with choosing a sample that will contain data suitable for answering research questions and allowing for the construction of convincing interpretations of these data. At some level, researchers are advised to choose any research setting that is easily accessible and will provide the data needed for their study. It is at this point that researchers should attempt to include deviant cases in their research, lest they select only cases that conform to their a priori expectations. By actively seeking out deviant or negative cases, researchers increase the likelihood of creating a robust set of findings that have relevance in a wide range of contexts.

Once sampling decisions have been made and data collection is underway, embracing deviant or negative cases and incorporating them into the interpretation of data is an ideal way to increase the trustworthiness of research findings. This concern is expressed by all qualitative researchers in one way or another, because findings in which little confidence can be placed are likely to be dismissed as insignificant or flawed. Silverman rather stridently

asserts the need for the findings of qualitative research to have a ring of truth about them. To defend against anecdotalism or claims based only on data that confirms initial ideas, researchers should clearly identify contrary cases and show how their findings are based on detailed analysis of *all* data rather than some well-chosen examples. Using deviant cases, processes or outcomes revealed in the data that are in some way atypical gives credence to research findings by showing that every piece of data is accounted for.

Once data collection and analysis are complete, researchers are left with the job of disseminating their findings. The peer-reviewed journal is the most common place for this to occur, with articles being published that make some kind of contribution to knowledge in a particular discipline. The challenge for authors is how to present in these outlets, which have a relatively small amount of space, analytical explanations based on large bodies of qualitative data. Jennifer Mason presents this as a challenge of making arguments: the construction of a perspective, interpretation, way of thinking, or way of viewing the world. The goal is to make these arguments convincing, which comes down to engaging readers and providing them the proof they need to accept the arguments presented. Findings will attract even greater attention when generalizability or transferability are addressed, which deviant case analysis can help accomplish. The means for doing this is in showing how the explanations and arguments presented have been subject to careful scrutiny, especially from alternative explanations that may be present in deviant cases or negative instances. As previously discussed, this should be embedded in the design of research (what gets studied) and in the analysis of data (how interpretations are formed). The deviant case plays a special role here, allowing the researcher the opportunity to show how data that run counter to the theoretical explanations being developed are incorporated into research findings. In this way, a study's findings can be presented in a highly convincing manner, based on sound methodological principles that demonstrate a systematic and thorough approach to data collection and analysis, a set of conclusions or interpretations that logically flow from that analysis, and the rigor of interpretation that comes from putting it to the test of deviant or negative cases.

### Critical Summary

Deviant case analysis is an important element of qualitative research in terms of its ability to defend against anecdotalism and provide the opportunity for wider theoretical resonance of findings. The idea of a deviant or negative case is at the heart of testing the limits of extant theory, in particular as it relates to the presence of and relationship between theoretical constructs, and the generalizability of theory itself. There is something intrinsically interesting about analyzing a case in which something predicted to occur does not. Examining only cases in which expected results occurs serves to limit the contribution to knowledge that a study can make, arguably the epistemological basis of scholarly research. The deviant case can be incorporated by design as a sampling strategy, occur naturally as counterintuitive data are collected, and be used to demonstrate trustworthiness of findings. Using deviant or negative cases allows for the possibility of identifying concepts that are present but have no effect on what is being studied as well as pointing to ways in which concepts can be introduced or rearranged to clarify or extend existing theories.

## DIAGNOSTIC CASE STUDY RESEARCH

---

Interest in diagnosis can be traced back several thousand years. Ancient Egyptian observers, for

example, provided diagnostic descriptions for, among other things, epilepsy, alcoholism, and mental retardation. These early attempts at classification were undoubtedly based on intensive investigations of a single person. Today, these intense investigations of single organisms are called *case studies*. Whereas the general scope of inquiry for case studies is, at least theoretically, limited only by the creativity of the researcher and the complexity of the organism that is being studied, diagnostic case studies have a much narrower focus on disease. More specifically, *diagnostic case studies* are case studies that focus exclusively on the identification, classification, and understanding of disease.

### Conceptual Overview and Discussion

Diagnostic case studies focus their inquiries at the level of the individual and involve a systematic search for pathology of some sort. The primary goal of diagnostic case studies is classification. Scientific classification requires that a given phenomenon—in this case, a disease—be identifiable in a manner that distinguishes it from other phenomena. By identifying distinguishable disease entities researchers who perform diagnostic case studies contribute to a body of science that allows other researchers and practicing clinicians to communicate more effectively. This enhanced communication, in turn, fosters a deeper understanding of a disorder so that practicing clinicians can more effectively assess and treat patients.

Beyond an intensive focus on the individual, the essential features of diagnostic case studies are (a) systematic assessment, (b) repeated measurement across time, (c) clear operational definitions, and (d) replication. *Systematic assessment* includes using standardized procedures and well-validated instruments. *Repeated measurement* is required to reduce the likelihood that extraneous factors are influencing the outcome of the study. *Operational definitions* precisely specify how a variable is measured. Without clear operational definitions, *replication* by other researchers is not possible, and all scientific knowledge should be replicable or else its validity is questionable.

The diagnostic process formally begins once all pertinent data have been collected. The data collection process requires an extensive personal

interview and, ideally, formal testing. Modern diagnostic endeavors in mental health are based on the principles of parsimony and hierarchy. The principle of *parsimony* requires that one account for all available data with the fewest possible diagnoses. A single diagnosis that accounts for all observations is always the preferred option. The principle of *hierarchy* notes that mental illnesses cluster in a hierarchy of syndromes that tend to vary in severity. The most severe disorder that accounts for all the data is the most parsimonious diagnostic option. In practice, diagnostic endeavors follow a decision tree model. A diagnostic decision tree is a flowchart that allows a clinician to identify the most parsimonious diagnosis that fits the available data. Several decision trees are often required before one can arrive at the most parsimonious diagnosis.

In an applied setting (i.e., a doctor's office) the case study subject is the patient, and the data referred to earlier are called *signs* and *symptoms*. *Symptoms* are the complaints reported by a patient (e.g., a headache, hearing voices) and therefore are not directly observable. *Signs*, on the other hand, are directly observable and measurable (e.g., crying, a rash). Because symptoms cannot be directly observed, they are less reliable and carry less weight when rendering a diagnosis. Until very recently, diagnostic endeavors depended heavily on the skill of the clinicians or researcher and thus were often unreliable. Empirically validated diagnostic tests have now been developed for many conditions, adding considerable objectivity and rigor to the diagnostic process.

### Application

Diagnostic case studies provide unparalleled insight into illness at the individual level of affliction. These rich data have provided the foundations for many of the grand theories in psychology. Sigmund Freud, for example, developed the vast architecture of psychoanalysis from case study observations. Although many of his findings were subsequently refuted, psychoanalytic thought remains a viable and influential theory of mental illness. Diagnostic case studies, therefore, serve an important theory-building function.

The richly nuanced data that are gained from appropriately conducted diagnostic case studies can

also be used to assess treatment efficacy at the level of the individual. Although more labor intensive than a single large-scale study, a series of case studies can identify subtle individual differences in treatment response that are typically obscured by the averaging effects that result from group comparisons. In fact, diagnostic case studies are the only investigative method that will provide data on treatment effectiveness at the level of the individual.

The data generated by an appropriately conducted series of diagnostic case studies can also be used to generate hypotheses for subsequent investigation with more statistically robust large-scale studies. Thus, case studies can serve as frontline exploratory investigations that help focus larger follow-up inquiries.

### Critical Summary

Although few would argue against the hegemony of group-design methods in science, an exclusive reliance on group research designs seems illogical when the ultimate focus is the individual. Clinical psychology and psychiatry are obvious examples of disciplines that ultimately have the individual as their focus. These disciplines can be ill served by an excessive reliance on research designs that obscure individual differences by averaging results across large groups of research participants. Case studies are the only scientific method for exploring the richness and diversity of the individual.

Unfortunately, case study designs lack the rigorous control of group designs. The data generated by diagnostic case studies are also difficult to generalize to a broader population. Thus, the individual level of analysis that is characteristic of the case study method must be supplemented by the group-level analysis offered by large-scale studies. Ideally, these two methods of inquiry should coexist to generate a richly detailed understanding that can be generalized to the population at large.

---

## DIALECTICAL MATERIALISM

---

Dialectical materialism has been defined both as a *natural philosophy*—a philosophical generalization of the most fundamental truths disclosed by the natural sciences and by the Marxist social science of historical materialism—and as a *method of inquiry* committed to a realist approach in epistemology and to materialist–monism in ontology. At the most general level it represents an attempt to synthesize elements of two preexisting philosophical traditions: (1) the philosophical materialism of the European Enlightenment and (2) the dialectical logic of the German idealist philosopher G. W. F. Hegel. Hegel’s dialectics are conceived as a corrective to the mechanical determinism of traditional materialism, and materialism is seen as the appropriate basis for challenging the absolute idealism of Hegel’s system.

### Conceptual Overview and Discussion

If historical materialism is generally regarded as the *science* of Marxism, then dialectical materialism is widely considered to be the its *philosophical* foundation—although this view has been challenged by many who argue that Karl Marx’s *scientific socialism* involves a kind of transcendence of philosophy or that Marxism is a variety of humanism. The term is sufficiently elastic, however, to accommodate a wide variety of perspectives within an ecumenically defined Marxist tradition. Thus, proponents of dialectical materialism (or the *materialist dialectic*) include humanists who emphasize the role of conscious activity and the subjective factor in shaping human outcomes as well as

anti-humanist structuralists who argue that human activities and intentions are mere effects of the autonomous interplay of forces and relations of production within determinate modes of production. (Despite this elasticity of interpretation, however, many Marxists have eschewed dialectical materialism in large part because of its baleful association with the mechanicism of the Second International and, especially, the rigid dogmas of Stalinism.) Dialectical materialism has inspired a tremendous variety of case studies within both the natural and social sciences, and the fact that it has been understood and applied in Marxist thought in so many different ways invites a case study approach to the topic of dialectical materialism itself, as well as the implications of its basic principles for case study methodology.

In his *Theses on Feuerbach* of 1845, Marx suggested that his “new materialism” incorporates the traditional idealist concern with “the active side” in human affairs while also insisting on the essentially sensuous (material) character of human activity. In his 1873 postface to the second edition of *Capital*, he wrote the following:

My dialectical method is, in its foundations, not only different from the Hegelian, but exactly opposite to it. For Hegel, the process of thinking, which he even transforms into an independent subject, under the name of “the Idea,” is the creator of the real world, and the real world is only the external appearance of the idea. With me, the reverse is true: the ideal is nothing but the material world reflected in the mind of man, and translated into forms of thought. (Marx, 1977, p. 102)

What is common to Hegelian and Marxist dialectics is the conviction that reality must be grasped as a unified totality that is subject to incessant change and that is, in principle, *knowable* by human consciousness. In the most general sense, then, dialectic is the logic of an ever-changing reality. But the question is posed: Does this logic belong to reality itself, or is it simply a set of principles employed by the human mind to grasp what is happening beyond it? If mind is internally related to everything else that exists, then this question is basically meaningless, for if mind and material reality are not metaphysically separated and absolutely distinct from one another but instead form a

contradictory unity of opposites, whether grounded in physical matter or in an incorporeal consciousness, then mind and reality are *one* in a fundamental ontological sense. A consistently dialectical worldview is therefore also a *monistic* one—an ontology that refuses the dualistic division of reality into absolutely separate worlds (e.g., the material and the ideal or the natural and the supernatural). Yet this unified reality is subject to considerable differentiation, resulting in the interaction of a great many distinguishable elements. It is the mutual relations and motion of these elements that dialectical logic seeks to grasp.

At the very heart of dialectical thought is the idea that the conflict of opposites within a larger unity (the *law of contradiction*) is the main driving force behind the process of change. For Hegel, change-inducing conflict occurs within a spiritually grounded consciousness (the *process of thinking*, as Marx put it), whereas for Marx it occurs within the “material world.”

While insisting on the need to extract the “rational kernel” from the “mystical shell” of Hegel’s philosophy, Marx never gave a clear exposition of his own dialectical method. His *Capital* may nevertheless be read as a specific application of a number of key dialectical principles to a particular object of investigation: the capitalist mode of production. Among these principles are (a) the movement from the abstract to the concrete, (b) the systematic ordering of concepts, (c) the contradictory unity of opposites, (d) the transformation of quantitative changes into qualitative ones, and (e) the negation of the negation. It was left to his collaborator Frederick Engels to give a more schematic and philosophical presentation of some of these principles in such works as *Anti-Duehring* and *Ludwig Feuerbach and the End of Classical German Philosophy*. A posthumously published work, *The Dialectics of Nature*, suggests that, for Engels at least, dialectic was not simply a method (of a conscious subject involved in active relations with various objects) but a set of universal ontological principles, applicable to both the natural and the human world. Although it is doubtful that Engels intended it, this “ontological” understanding of a dialectically structured reality opened the way for an anti-humanist interpretation of the materialist dialectic—one that typically fails to register the causal efficacy of *conscious activity* in human affairs.

As the official dogma of the Soviet Union and the international Communist movement over several decades, the Stalinist version of dialectical materialism played down the subject–object dialectic that Marx and Engels inherited from Hegel in favor of a naturalization of the laws of social development disclosed by Marxist social science (historical materialism). In doing so, it asserted that human history is governed by the same inexorable dialectical laws that govern the natural world. The result was a version of dialectical materialism that pushed historical materialism toward economic determinism—the view that only the economic base of society possesses causal efficacy and that political, theoretical, and ideological factors belonging to the social superstructure are purely epiphenomenal. Indeed, in its crudest form this economic determinism accorded a privileged role in social development to technological change (the expansion of productive forces within specific modes of production). Stalinist *diamat* may therefore be understood as a reversion to mechanical materialism.

Marx and Engels pioneered a materialist conception of history (later referred to as *historical materialism*), but they never used the expression *dialectical materialism*. That term was coined in 1891 by the Russian Marxist Plekhanov, who lacked access to many of Marx’s early, more philosophical writings. The eventual publication of Marx and Engels’s *The German Ideology* and especially Marx’s *Economic and Philosophic Manuscripts of 1844* stimulated a proliferation of challenges to Plekhanov’s orthodox Marxism—an important pillar of both Second International Marxism and Soviet Communism. In later years, these challenges also took the form of a critical examination of Vladimir Lenin’s *Materialism and Empirio-Criticism* of 1908 in light of Lenin’s more mature (i.e., dialectical) views in his *Philosophical Notebooks*.

In the 1920s and 1930s, Western Marxist challenges to orthodox Plekhanov-style dialectical materialism were mounted by Hegelian-inclined Marxists such as Karl Korsch, George Lukacs, and Antonio Gramsci, who viewed the Bolshevik Revolution of 1917 as a practical refutation of the Second International’s mechanical materialism and a triumph of revolutionary consciousness and praxis. In their own ways, these theorists sought to

provide the international communist movement with a philosophy adequate to its ostensible programmatic ambition: world socialist revolution. However, this “Hegelianized Marxism” was denounced by more authoritative figures within the Third International, such as Zinoviev, as an unacceptable departure from genuine Marxism. A later generation of Western Marxist theorists, associated with Della Volpe’s positivism, Althusser’s structuralism, and Colletti’s neo-Kantianism, deployed more sophisticated arguments to purge Marxism of its Hegelian and humanist residues, often drawing on intellectual traditions expressly critical of dialectical logic. In doing this, many of these theorists sought to overcome the contradiction between the formal allegiance of world communism to dialectics and its actual commitment to more pragmatic, empiricist, and mechanistic perspectives.

The history of the controversy surrounding dialectical materialism reveals much more than the susceptibility of Marx and Engels’s “communist world outlook” to different philosophical interpretations. More important, it demonstrates the way in which programmatic considerations have dominated and shaped theoretical ones within ostensibly Marxist thought. The dialectical interplay of theory and program is one in which *program* is almost always the dominant term. This can be demonstrated by adopting a case study approach to the development, diffusion, and critique of dialectical materialism itself. Marxists drawn to more mechanical or structuralist interpretations have most commonly associated themselves with gradualist or reformist programmatic orientations and are given to citing the “immaturity of the objective conditions” as a rationale for a nonrevolutionary practice. Conversely, Marxists drawn to more voluntarist interpretations that emphasize the role of conscious human agency in social change have generally also been proponents of a revolutionary program. Among the latter, those who are most impatient for revolutionary action are also the most likely to downplay the importance of material conditions and emphasize the role of sheer will in effecting a fundamental social transformation.

### Application

As the official philosophy of the Union of Soviet Socialist Republics, the Stalinist version of dialecti-

cal materialism exerted a profound influence over Soviet scholarship for many decades, shaping the research agendas not only of historians, psychologists, and social scientists but of natural scientists as well. The application of the laws of dialectical materialism produced a plethora of studies of widely varying quality. The most infamous was undoubtedly the work of Trofim Lysenko, who claimed that it was possible to dramatically improve crop yields by changing the physical characteristics of seeds through simple manipulations of temperature and moisture and that the effects of these changes could be passed on to succeeding generations—a version of the Lamarckian theory of the inheritance of acquired characteristics. Lysenkoism had a disastrous impact on the progress of agronomy and genetics in the Soviet Union. Even so, it was officially sanctioned by the Soviet ruling elite under Stalin and Khrushchev because of its apparent affinity to such dialectical laws as “quantity into quality” and the “negation of the negation.” In the West, the case of Lysenko was often cited during the Cold War as an object lesson in the dangers of state ideological interference in science and the absurdity of dialectical materialism.

The influence of dialectical materialism on the work of scholars and intellectuals, in the communist world and elsewhere, has not always been so negative. In the realm of the natural sciences, for example, a nondogmatic materialist dialectic has been put to good use by Richard Levin and Richard Lewontin in their book *The Dialectical Biologist*, and John Bellamy Foster applied it intelligently in his elaboration of *Marx’s Ecology*. Within Marxist political economy, the concepts of dialectical materialism have been indispensable to the development of more sophisticated versions of value theory and the theory of capitalist crisis. For example, the work of Tony Smith has demonstrated how a systematic dialectical methodology can help scholars to order and develop their concepts in such a way as to more effectively synthesize the empirical evidence and theoretical insights presented by contending schools of Marxist and non-Marxist thought. Smith has produced important studies of lean production and globalization that illustrate the fruitfulness of this methodology and that have made important strides in completing Marx’s unfinished theoretical agenda for *Capital*.

Within Marxist historiography, the principles of dialectical materialism have inspired ways of thinking about historical events and processes that have often been highly insightful, but it has always been in the realm of Marxist politics that dialectical materialism has had its greatest impact, with more “mechanical” versions informing and rationalizing the national-reformist theories and projects of social democracy and Stalinism and more truly dialectical versions providing philosophical support to such revolutionary alternatives as Trotskyism and council communism. Thus, in the conflict between Stalin’s conception of building socialism in one country and Trotsky’s theory and strategic perspective of permanent revolution, the former was plainly committed to a view of human history that was mechanical and stageist, whereas the latter based itself on a more dialectical conception of uneven and combined development on a world scale. Dialectical conceptions also inform Trotsky’s characterization of the Soviet Union under Stalin as a *degenerated workers state*—a hybrid or transitional social formation in which the economic structures brought into being by the Russian socialist revolution continued to serve the historical interests of the working class but in which political power was monopolized by a privileged bureaucratic oligarchy that posed a threat to their survival. Trotsky’s case study of the Soviet Union in *The Revolution Betrayed* (1937) is an exemplar of how dialectical materialism can be applied to analyzing the social phenomenon of Stalinism, yet other Marxists, also claiming to base themselves on the methods of dialectical materialism, have drawn very different conclusions. For example, Raya Dunayevskaya and C.L.R. James employed a more Hegelian and humanist interpretation of Marxist philosophy to support the claim that the Soviet Union under Stalin was a form of state capitalism.

### Critical Summary

What these controversies point to is the conclusion that the materialist dialectic is not a method that leads ineluctably to definite conclusions. By itself, it can “prove” nothing about the nature of reality. At its best, it is simply an aid to reason and to open-ended empirical research—a stimulus to consider specific problems (in particular, those pertaining to the dynamic interplay of the natural, the

social, and conscious activity) in ways that are alert to the inherently contradictory nature of reality, that view things in terms of their empirically real interconnections with other things, and that refuse the bifurcation of reality into metaphysically separated worlds. Case study research strategies can benefit from dialectical materialism insofar as it is treated not as a dogma but as a methodological antidote to the subjectivism, idealism, and dualism that inform much of contemporary non-Marxist social science.

## DIALOGIC INQUIRY

---

Dialogic inquiry emerges from the theoretical assertions of M. M. Bakhtin. Bakhtin’s theories,

originally situated in the analysis of literary genres, examine the cultural and social context of language as a complex, negotiated, meaning-making system. Dialogic inquiry is an approach to research that examines the active and responsive nature of language among participants in appropriating, constructing, and reconstructing knowledge for self and other.

### Conceptual Overview and Discussion

According to Bakhtin, all human consciousness and experiences come into cognition through language, or language-in-use. *Language-in-use* refers to complex systems of language (including texts, artifacts, speech, gestures, conversations, socially accepted actions, customs, etc.) that produce, inform, and are continually informed by knowledge of self, other, society, culture, and so forth. Language-in-use can also be described as *discourse*.

Bakhtin claims that discourse is not neutral, but rather (over) populated with the intentions, histories, beliefs, and so forth, of others. Consequently, discourse is seen as socially constructed, situated, and continually informed by past and present contexts. Discourse is perceived as potentially transformative and replete with tensions as one negotiates multiple perspectives. As such, individuals are understood to be dynamic and evolving entities, potentially affected and changed by discourse, and possess the potential to affect change for another. Bakhtin refers to this as *ideologically becoming*.

Bakhtin defines two types of discourse: (1) authoritative discourse and (2) internally persuasive discourse. *Authoritative discourse* can be viewed as discourse that carries unquestionable authority and power and is taken as given without critique or question. In contrast, *internally persuasive discourse* is discourse that is one's own and is reflective of autonomous thought. Human consciousness, according to Bakhtin, is a continuous negotiation of tensions between authoritative and internally persuasive discourse.

More recent conceptualizations of dialogic inquiry have been taken up by others, such as Gordon Wells. Wells, building on Bakhtin's conceptualization of dialogism, proposes the *dialogic inquiry approach* to learning and knowledge construction. This model emphasizes (a) the role of

experience in shaping learning; (b) the role of internalization of external stimuli; (c) the active construction of knowledge through a meaningful appropriation and perhaps modification and improvement of external stimuli; and (d) over time, achieving an understanding of stimuli such that the knowledge becomes integrated into the individual's experiences. The approach is iterative.

When approaching case studies from a dialogic inquiry approach, Bakhtin's theoretical view of discourse shapes and precedes methodology. As a result, significant consideration needs to be given to the ways in which data are collected and subsequently analyzed. Careful attention to language; context; culture; and sociopolitical, socioeconomic, and historical perspective is required to develop cases for analysis. A continuous iterative evaluation of the results is necessary to establish the ways in which discourse shapes and reshapes individuals both internally and relationally.

The complexities associated with characterizing authoritative and internally persuasive discourses should not be underestimated. As Bakhtin explains, often discourses are simultaneously authoritative and internally persuasive, and clear distinctions may not be readily evident without perhaps some cross-analysis of multiple data sources. Cases are analyzed from the stance of interrogating multiple-voiced perspectives and the ways in which those perspectives are potentially internalized. Case studies emerging from a dialogic perspective often offer competing alternative perspectives of phenomena.

Research questions appropriate for case studies utilizing a dialogic framework might include those (a) directed at gaining a deeper understanding of phenomena, from multiple perspectives; (b) examining changes in belief systems over and throughout time; (c) analyzing the sociocultural implications of power, and so forth. In all cases, the theoretical lens of dialogic inquiry frames the methods used to undertake the research. Research of this nature is deeply embedded in theory. The end purpose of dialogic inquiry is not necessarily more theory, or more generalizability, but rather understanding.

### Application

Two examples of dialogic inquiry, from a Bakhtin perspective, in case study research are Scott Bulfin

and Sue North's study of digital literacy practices of youth and Barbara G. Pace's cross-case analysis of two college-level students' responses to critical literacy readings.

Bulfin and North's case studies of 20 youth, aged 15 and 16, investigated the ways in which digital technology practices of the youth "rubbed up" against those of authoritative figures and how those practices transcended school-home boundaries. Data sources included interview recordings and transcripts; student media use diaries; field and observation notes from school and home visits; and other documents and artifacts, including online documents (MSN conversations, e-mails), photos, and digital video (also from students' phones and digital cameras). The collection of data sources formed the "texts" from which the analysis occurred and the cases were constructed.

Bulfin and North describe somewhat obvious sources of authoritative discourses, common to both home and school, which include restricted Internet access, limited usage (i.e., digital phones, online time, etc.), and privileged usage (i.e., computer as a homework tool). The noteworthy aspect of these case studies was the way in which students exercised internally persuasive discourses, often in subversive and nonapparent ways. For example, Bulfin and North describe how one student created fictitious Websites with "safe" names (e.g., "weather") to bypass sites commonly blocked on school-based computers.

Another student described how appearing attentive in class concealed her prohibited use of an MP3 player during classroom instruction. In short, Bulfin and North demonstrate multiple ways that students found to negotiate tensions between completing discourses in both the home and at school. Bulfin and North conclude that both home and school are negotiated spaces for youth with respect to digital technology. The authors propose that literacy education could benefit from an understanding of these negotiated spaces, rather than dismissing the popularized culture that students actively seek as irrelevant to learning. The students across these case studies found ways in which to engage in the forbidden or internally persuasive discourse, despite the authoritative discourse.

Pace's research investigated the ways in which two students in a writing-about-literature class responded and interpreted events in a story. In this

study, Pace focused on two female students for a cross-case analysis to examine the how the students' initial private responses shifted (or not) following whole-class discussions regarding a story about a woman confined to her bedroom by her husband.

The first student, Kavita, was of Indian descent and had immigrated to the United States prior to the ninth grade. The second student, Jennifer, was white and a U.S. native. Data sources included student reading-response journals; transcripts; and field notes from the 2 days of class discussions, interview data, and final analytical essays.

Pace saw evidence in the data that Kavita and Jennifer both recognized the central themes of the story as independence and identity. Kavita, through the course of her interviews, described her resistance to the expectation of marriage as an authoritative discourse within her culture, whereas Jennifer failed to understand the quest of the woman in the story and largely idealized marriage. Kavita initially asserted that the husband treated the woman as "child-like." Following whole-class discussions, which centered largely on the mental illness of the woman in the story and the actions of the husband, both students argued in their final essays that the main problem was societal understanding of mental illness versus the husband's treatment of his wife.

Both women, as they engaged with the text through the various data collection stages, demonstrated high adherence to authoritative discourses, despite tensions that may have arisen around the ethical dimensions of the treatment of the woman in the story, and despite their cultural differences. The comparison of the cases, through multiple data sources, demonstrates the pervasiveness of authoritative discourses and highlights the challenges educators must contemplate with respect to critical literacy.

### Critical Summary

Case study analysis from a dialogic-inquiry perspective focuses on complex views of language-in-use, or discourse. Cases examined from this stance represent a specific theoretical perspective on the role of language. Language is seen as a complex meaning-making system that is multivoiced and culturally and socially situated. Meaning-making

is a constant negotiation between competing tensions (i.e., authoritative and internally persuasive discourses). Case studies from this perspective illustrate the way in which discourse is shared and then revoiced by participants.

## DIARIES AND JOURNALS

---

Diaries and journals are research tools that require either the participants or the researcher to reflect on the research process or research study. Traditionally, they record their thoughts, ideas, questions, and topics for discussion. *Diaries* are regular, intimate, and contemporaneous, and they act as a written record of events. *Journals*, however, are sporadic, detached, and asynchronous, but they also act as a written record. In general, diaries are used more frequently by research participants, whereas journals are used by the researchers when the focus of the study is to investigate the same phenomenon.

### Conceptual Overview and Discussion

Diaries and journals case study research lends itself particularly well to investigating the central research question under review and can be used in

quantitative, qualitative, and mixed methods research studies. Historically, diaries and journals have been used for hundreds of years, from Sei Shonagon's *Pillow Book*, to Saxon monks, to Samuel Pepys's famous diary; however, as a clear research tool, diaries and journals have been used extensively over the past three centuries.

Dairies and journals have been used in varied disciplines for varied purposes. For instance, social historians have performed hermeneutic analyses of diaries that reveal the social conditions of the time period under study, the feelings of the diarists, the dress of the time, and the politics of the time, to name a few. Often, these sources of data are doubly important because other sources have been destroyed or heavily censored. Experimental researchers use diaries and journals extensively when survey data do not provide the type of information needed for close analysis of practical problems. For example, when a researcher wants to investigate the daily habits of a target group, a diary or journal works particularly well as the participant records his or her daily activities over a specific period of time. This close analysis of participants' routines cannot be revealed through other methods, such as questionnaires and interviews. Oftentimes, these entries act as a substitute for the researcher's recording his or her observations of a target group. Naturalistic or ethnographic researchers frequently access data through diaries and journals as a method of studying taken-for-granted elements of social interaction. In other words, ethnographers are able to extract information from participants in their natural settings and explore tacit knowledge without being overly intrusive. As well, the diarist or journalist controls the recorded information and the format of the diary or journal and often constructs his or her self-identity, which becomes invaluable information for the ethnographer.

At times, the researcher might focus the entries by creating a template to be followed loosely by the diarist, or the researcher might supply a guiding question or statement (e.g., "Describe how your day goes for the next two weeks with a particular emphasis on how you discuss issues with colleagues"). Often these frames provide a starting point for the diarist or journalist without sacrificing autonomy. These entries also provide rich data for the researcher.

Often the researcher is involved in reflection on both the content and the process of the research study, and diaries and journals act as a conduit for these reflections; that is, the researcher transforms standard field notes into critical reflection or critical self-reflection on the research study. At times, the information is related to fine-tuning the study itself (e.g., revising interview questions), but frequently the researcher records personal feelings in the diary or journal, which can serve to strengthen the interpretation of the data as the recorded thoughts are seen through a more personal lens.

Finally, in case study research, as technology becomes more sophisticated, diaries and journals can be recorded and analyzed using advanced computer software. For example, if the entries from a diary or journal are handwritten, they can be transcribed or scanned into a computer for analysis or directly imported if the diarist or journalist used a word processor or recorded on a Web log (i.e., a blog). These data can then be analyzed through a variety of methods. For instance, qualitative data such as diary entries can be *quantitized* by assigned numeric values to responses or using a statistical analysis (e.g., Rasch analysis). Also, quantitative data, such as how frequently a journalist performs a daily task, can be *qualitized* so that the researcher can deduce how important a daily activity is to the whole group under study. Clearly, diaries and journals data can easily enhance legitimation of the research results because they can be used with qualitative and quantitative analyses to ensure descriptive precision and numerical precision.

### Application

Two exemplars of diaries and journals research are Bronislaw Malinowski's seminal 1967 ethnographic study of the Trobriand Islanders in the 1910s, and Dawn Francis's 1995 study of preservice teachers' practical knowledge.

Malinowski's pioneering anthropological work not only laid the foundation for the study of simple and complex cultures but also established researcher field notes as a viable method of studying participants and formed the foundation for participant observation as a legitimate case study research method. Over the course of 2 years, he lived with the Trobriand Islanders, immersed himself in their culture, and learned their language. His focus was

to learn the ways of the islanders in a functional manner, so he studied their daily rituals and recorded his thoughts in a diary.

Each day, Malinowski recorded his observations of the Pacific Islanders and discussed his perceptions of their marriage, trade, and religious customs. Most significantly, he recorded not only what the Trobriand Islanders said about their religious beliefs, trade rituals, sexual practices, and marriage customs but also how these beliefs, rituals, practices, and customs all measured against the islanders' everyday lives. At times, his diary recorded mundane activities, but frequently Malinowski recorded his own perceptions of their beliefs and his own feelings of living with the people. For instance, he noted that when fishing in the lagoon, they acted in a straightforward matter, but when fishing beyond the lagoon, in more treacherous waters, the islanders performed magic rituals to increase their courage. What Malinowski's diary entries showed was that he admired their coping mechanism and showed that they had a systematic method of dealing with their fears while maintaining their social and economic structure of being fishermen. Similar entries revealed that he perceived no difference between their so-called primitive culture and the cultures of more sophisticated people; the Trobriand Islanders perceived reality at a similar level and created intelligent solutions to complex problems.

After his two stints with the Trobrianders, Malinowski's diary entries demonstrated that the anthropologists who studied cultures from a distance were incorrect in their assumptions that all cultures followed a linear development as espoused by the social Darwinists of the time. By living among the people and recording both their daily activities and his personal comments about the people, Malinowski provided significant anthropological case study data. He was not always favorable in his comments about the people, but many times his entries were objective, descriptive, and straightforward.

Malinowski's diary was translated from Polish, edited by his widow, and published several years after his death. It is not clear whether Malinowski would have wanted his diary published, but it has proven valuable for generations of researchers.

Dawn Francis employed reflective journals with bachelor of education students in their final year of

a 4-year degree. The students were required to keep a journal that was organized into four sections: (1) lesson plans, (2) reflection on workshops attended, (3) reflection on events that impacted their personal view of teaching, and (4) a critical summary of professional readings. The preservice teachers had full autonomy over the content and format of the entries but were required to stay within the parameters of the four sections.

The students were given time at the end of each lecture to record their thoughts, and the journals were collected at the end of each class. For the most part, the readers responded to the entries in nonjudgmental ways so that the students would not be inhibited when writing further entries.

The most salient findings from this study, and reflective of many studies using diaries and journals, were that the journalists needed to learn how to journal and needed to establish a commitment to journal writing. To wit, the preservice teachers learned that the most effective ways to write were to have a balance of structured activities and prompts with free-focus writing in which they could record their thoughts in a stream-of-consciousness manner. As well, they had to be allotted time to record their entries until the process became natural enough that they began to reflect in the journals outside of class time.

Malinowski's and Francis's studies demonstrate how diaries and journals can provide valuable information about case studies through a variety of lenses. Because of the personal nature of the method, diaries and journals reveal rich data about participants and researchers that are often omitted, ignored, or elusive when other research methods, such as surveys and interviews, are used.

### Critical Summary

Diaries and journals as case study research tools often examine the participant's self-reflection and critical self-reflections and the researcher's reflections on the design and analysis of the study. Diaries and journals research is powerful because it allows the participants to reveal their feelings in relation to the research study focus in a highly subjective manner but allows the researcher to objectify those feelings through a variety of data analysis methodologies and techniques.

## DIRECT OBSERVATION AS EVIDENCE

---

In case study research, multiple rather than single methods of data collection are employed. Direct observation as a source of evidence can contribute to the development of a strong case study. Direct observation provides an opportunity for researchers to observe directly what is happening in the social setting, interact with participants, and participate in activities.

### Conceptual Overview and Discussion

Direct observation may be referred to by other terms, including *participant observation*, *site visits*, or *field work*. Use of the term *participant observation* is closely linked to ethnographic research. Michael Patton, who has written extensively on qualitative research, indicated that direct observation provides insight into the taken-for-granted aspects of everyday activities that may go unreported by participants, gives the researcher direct experience of the phenomena being studied, and creates an opportunity to see and hear what is happening in a social setting rather than focusing solely on narrative descriptions of participants.

The nature of direct observation as a method of data collection will be shaped by the particular epistemological research tradition that is guiding the overall research project. Egon Guba and

Yvonne Lincoln proposed five paradigmatic perspectives that describe contrasting epistemological views. These epistemological perspectives include positivism, postpositivism, critical theory, constructivism, and participatory paradigms. The particular epistemological view taken in the research has methodological implications for decisions about the role of the researcher and the nature and focus of the observations.

Positivistic and postpositivistic paradigmatic views would suggest that the researcher takes the role of a detached observer, whereas other views would suggest there is engagement of the researcher as a participant, critic, or collaborator in the research. The researcher may just “hang out” or participate to varying degrees in the activities or roles within the setting being studied. As Michael Angrosino and Kimberly Mays de Perez observed, ethnicity, gender, and class, as well as social and cultural norms, will shape the researcher’s role in the social setting, influence the nature of observations and interactions, and generate different conclusions.

Observations may be structured or unstructured depending on the epistemological underpinnings of the research. In some types of case study research direct observation will be guided by specific checklists as a means of focusing on selected behaviors or activities that are the focus of the research. In other types of research observations may be completely unstructured at the beginning and become more selective over time. The research purpose and questions identified for the project should provide direction as to the focus and duration of observations. Periods of significant immersion are generally required for the researcher to integrate him- or herself into the setting and gain sufficient insight and experience for analysis.

Observation requires the development of skills in paying attention, locating oneself as an observer, and disciplined practice in writing field notes. Reliable and accurate observation means that researchers must be present in the moment in order to engage in, as Michael Patton described, “systematic seeing.” Systematic seeing is a disciplined approach to making observations that are accurate, reliable, and relevant to the focus of the research. A systematic approach to observation means that one is constantly aware of and attentive to what is going on in the setting at multiple levels. What is the nature of the setting? What are

people saying? What are people doing? What interactions are taking place? What else is going on? Which of these observations are relevant to the focus of the research? Disciplined observation requires immersion in the setting and constant questioning as to the meaning of observations. In order to generate insights from observations, researchers must be equally disciplined in acknowledging their own perspectives and positioning as a researcher and in the writing of field notes that capture valuable observations and clues as to the meaning of observations.

Robert Emerson, Rachel Fritz, and Linda Shaw have written extensively about writing field notes. In field notes the researcher records what he or she has seen, heard, felt, smelled, and experienced through his or her direct observation; they provide an opportunity to reflect on one’s own values, beliefs, and assumptions that may be influencing perceptions. In addition, field notes can be used to record analytic insights and methodological decisions. To enhance reliability and validity, researchers using direct observation should articulate their location in the research and be cognizant of factors affecting their location and experience as well as potential influences on what people say and do. These issues have been discussed in relation to emic/etic perspectives or insider/outsider debates. Discussion of observations and findings with participants can also enhance the reliability and validity of the research. Because direct observation is one source of data in a case study, the use of triangulation in data collection will also contribute to increasing rigor because comparisons, insights, and new understandings in the research will be generated through analysis of other data sources.

### Application

In a study that examined nursing practice in inner-city healthcare centers, Bernadette Pauly drew on critical and constructivist epistemological perspectives that shaped the focus of observations and her role as an observer. In this study observations were focused on the role that nurses played in facilitating access to healthcare for people who were street involved (e.g., homeless or using drugs). In particular, the focus of observations was on the nature of interactions between nurses and the persons accessing care within the context of an inner-city

healthcare center. Pauly was particularly interested in the enactment of ethical nursing practice that fostered access to healthcare, so she observed and documented what nurses did and said, and she looked for responses from those accessing healthcare and clues that would illuminate an understanding of the impact of the cultural context on nursing practice and access to healthcare. Initially, Pauly was attentive to all aspects of the setting, such as the physical location/layout, organizational structure, type of services provided and by whom, people accessing the center, relationship to other relevant organizations, background/experience of participants, important issues or dominant concerns of participants, dominant values, and organizational norms. This initial phase of paying attention with all of one's senses was important for getting a big picture or general survey of the setting and was followed by a phase of more focused observation and inquiry. As the research progressed, observations became more focused on the knowledge, attitudes, values, and beliefs of registered nurses that were consistent with enhancing access to healthcare and the corresponding factors that reduced access to healthcare.

Pauly began with an assumption that she would be a participant in the setting and negotiated her role with the participants. Initially, she acted as an observer, following nurses in their everyday activities. Over the course of the study, she participated as a nurse, receptionist, and team member. It was possible for her to take on these roles as participants came to trust her and because she was already a registered nurse with 20 years of experience in healthcare. It is expected that the role of the researcher may change over the course of the research and will need to be negotiated to determine the least disruptive approach that is consistent with the goals of the research. Being engaged actively in the setting gave Pauly an opportunity to make up-close observations from different points of view that informed her understanding of the cultural context. For example, acting as a receptionist and answering the phone or welcoming people coming to the clinic gave her an opportunity to see and make observations from the perspective of people entering the clinic setting and thus gain a better sense of the overall structure and organization of the clinics and cultural milieu.

At the beginning of the study, Pauly was advised to identify herself to clients as a registered nurse

and researcher, because registered nurses working in the inner-city health clinics were among those most trusted by people who came to the clinic. However, this positioning as a nurse meant that she was provided with information by clients that they thought appropriate to share with nurses and thus acted as a factor that shaped the information they provided. In some regard, being a registered nurse gave her access to experiences that other researchers might not have gained, such as ease of entry into clinic rooms and freedom to move on the street when doing outreach. However, this positioning likely restricted access to drug culture and street activities such as the sex trade or drug dealing.

Researchers conducting research that involves direct observation often enter into a setting that may be unfamiliar to them. This has the benefit of providing a fresh perspective from which to make observations and the ability to bring to light everyday events and activities that might go unnoticed by those who are already participants in the setting. Although Pauly was an experienced nurse, she had not worked previously in inner-city healthcare centers, and she had limited experience with issues related to homelessness and substance use. Nurse participants in the study felt that the research brought attention and value to aspects of their practice that often went unnoticed. In other examples, the researcher may already be an active participant in the setting before becoming a researcher. This can facilitate entry into, trust, and acceptance in the setting. It may also provide access to perspectives and experiences inaccessible to outsiders. A disadvantage is that such positioning may limit the researcher's ability to see taken-for-granted aspects of everyday life. Negotiating researcher roles for those already immersed in the setting may create confusion for participants, and thus it may be ethically impossible in the context of preexisting relationships, such as manager/employer and service provider/client, to conduct research in one's own setting.

The use of direct observation requires particular attention to issues of consent in the planning and implementation phase of the research process. Covert data collection is rarely if ever acceptable by current ethical research standards. Consent may be written or verbal. For example, in Pauly's research in inner-city healthcare centers written consent was used for primary nurse participants

and verbal consent was used for secondary participants, such as clients who were not the primary focus of observation. Informed consent can sometimes be challenging to obtain given time constraints, relationships with participants, and the nature of the observations being made. It is often difficult to determine in advance how or what data from observations will be used in a report of the findings. Thus, it may be important in some studies to return to participants to gain consent for inclusion of particular information or data.

### Critical Summary

Direct observation provides a unique perspective for the researcher to obtain data for case study research. It is essential to make explicit the underlying research tradition to guide methodological decision making related to the role of the researcher and the nature and focus of observations. In the conduct of the research, disciplined practice is required to enhance the rigor of the research, and awareness and thoughtful reflection are needed to address challenging issues related to ethics and power.

## DISCOURSE ANALYSIS

---

The term *discourse* and its adjective, *discursive*, are not meaningful research terms unless modified by additional descriptors. One can say something about *Foucauldian* or *Derridean* discourse analysis, *critical* discourse analysis, *narrative* discursive approaches, and so forth, but one should be wary of any research claiming merely to be “discursive” and any methodology claiming only to analyze “discourse.” As a term in common parlance since at least the mid-16th century, *discourse* is legitimately used to describe any speech, any conversation, and any process of reasoning. It may even still be used in its original etymological sense, meaning “to run to and fro.” Anyone whose research is spoken or written—that is, anyone—may claim with some justification that such research is discursive.

### Conceptual Overview and Discussion

Approaches to social science research claiming to be discursive in a specifically methodological and/or epistemological sense began to appear in social science theorizing in the 1980s, usually in scholarship claiming either to be *deconstructive*, with reference to the work of Jacques Derrida, or *genealogical* or *archaeological*, with reference to the scholarship of Michel Foucault. Derrida and Foucault do not stand alone, but they, far more than their colleagues (including Deleuze and Guattari, Kristeva, Spivak, Baudrillard, and others) have become popular in the English-language social sciences. Much of this discursive work has claimed to be, or has been labeled by others, *post-structuralist* or *postmodernist*. Such work can be understood to represent one variety of anti-essentialist, or social constructionist, thought.

Conceptually, such work is grounded in Saussurian linguistics.

From this perspective, one can speak meaningfully of *discursive systems* as an object of analysis. When used this way, a discursive system has much in common with a paradigm as described by Thomas Kuhn in *The Structure of Scientific Revolutions*. In both cases, the reference is to a system of interlinked assumptions, values, beliefs, and interpretations forming a specific common sense about what is real, true, good, and important. The main difference between these terms would be that calling such common sense a discursive system directs one to look at this system through a linguistic lens, considering text as the data for analysis that will yield information about the underlying beliefs and their consequences. One must be careful not to automatically assume that the term *discourse* is being used in this way when one encounters it because, like the term *paradigm*, it has been used in a plethora of ways, some incompatible with each other, some questionable in their own right.

Broadly speaking, these approaches to scholarship are all heirs to the phenomenological philosophical tradition. One broad cluster of positions within this tradition, a cluster primarily indebted to Hegel, attempts to derive from interpretive reality an underlying, hermeneutic truth. Recent heirs to this tradition would include Hans-Georg Gadamer and Jürgen Habermas. Another, perhaps broader cluster emerging from this tradition abandons the idea of objective truth for more constructionist/anti-essentialist assumptions within which reality is treated less as an objective thing to be discovered and more as a complex, multiply determined entity whose meanings are socially produced. The distinctive quality of discursive approaches to research would be reliance on the root metaphor of *textuality*.

If reality is a social product, it follows that the structure of a society's language contains evidence of the process by which that reality is produced and that determines the boundaries to what can and cannot be real within that common sense. When Foucault referred to his early work as *archaeological*, it was in this sense. Like an archaeologist digging through an ancient city, a "city of language" (a metaphor originating with Ludwig Wittgenstein), Foucault was exploring in language the sedimented evidence of the assumptions; the

values; the common sense through which, for instance, a phenomenon such as madness could have one set of meanings in one era and a contradictory set of meanings in another.

### *Textuality as a Root Metaphor*

In a review of the organizational culture literature in the early 1980s, Linda Smircich distinguished between scholars who treat culture as a variable and those for whom it is a *root metaphor*. For the latter group, culture becomes the lens through which sense data are interpreted. Culture is not a topic among others; instead, all reality is significant to the extent that it is represented in cultural terms. From this perspective meanings are, axiomatically, cultural meanings. Analogously, for a Freudian psychologist sexuality is a root metaphor; psychodynamic processes are interpreted through a lens of sexuality. Marxian theories of surplus labor value appropriation constitute a root metaphor for Marxists. It is in this sense that textuality can form a viable root metaphor for analysis of social reality as discourse, as discursive systems—as *text*. It is not that everything is really text but that everything that has meaning functions textually and can be studied through the root metaphor lens of discourse.

One might, for instance, look at the discourse of universal human rights in Western history. Whatever good and bad has been done in the name of these values, there is an identifiable set of core statements and beliefs that powerfully affect actions, from political colonization of much of the world in past centuries to the recent American war on terror. The discourse of human rights has provided a language of social progress, of the "white man's burden," of liberating people and of democratizing. The relationship among knowledge, power, and action in these highly influential events can be profitably studied by seeking the data contained in text as evidence. Although there have been multiple approaches to discursive analysis, all tend toward one of two poles on an essentialist–anti-essentialist epistemological continuum. Empiricist approaches, including, for instance, Peircean, Chomskian, and critical realist perspectives, are grounded in the assumption that language is a reflection of an underlying reality. The role of analysis, then, is to clarify language to

make it a nondistorting conduit for that underlying reality. Moving toward the opposite end of the continuum, many interpretive, poststructuralist, postcolonial, and related perspectives assume a more constructivist view of reality; that is, although physical reality is presumed to exist, we have no direct evidence of this reality except as it is mediated through socially constructed interpretations. Therefore, reality, understood as *meaning*, is literally a *product of* language. Consequently, one cannot seek “true” meanings. One can only elaborate how meanings are produced, foregrounded, marginalized, and shaped by social interaction that leaves its evidence in language.

For example, one might consider the tension between Frankfurt School critical theorists and French poststructuralists. Although the Germans, such as Habermas, conceded a high degree of constructivism, ambiguity, and interpretation to our knowledge of reality, they remain devoted to the search for transcendent meanings that reflect, if imperfectly, reality. We might contrast this with the major works of Foucault, who repeatedly attempted to show how fundamental notions such as insanity, crime, or sexuality changed so profoundly from one cultural epoch to another that there could be nothing about the notions that could be said to have meanings that transcended the situational.

For example, if one were to study representation of women in popular magazines from a feminist perspective, a Habermasian analysis would be directed toward showing how the underlying truth of gender equality is masked and distorted by representation. A more Foucauldian analysis would be epistemologically unable to claim to know an underlying truth; it would be restricted to showing competing representations and analyzing the differing consequences of differing representations. One might then advocate one representation over another, but this must be acknowledged as a value-based act. It cannot be legitimated with reference to objective truth or reality.

### *Speech Acts and Rules Governing Speech Acts*

One can study the structure of a language, or one can study how individuals and groups use a language. Either is a legitimate object of study, but it is important to distinguish between the two. The latter is about what *is* done in a *specific* instance. The

former is about what *can be* done in *any* instance. For instance, suppose one conducted participant research with a group of salespeople with attention to the uses of humor by informants. It is possible that analysis of one’s field notes would reveal patterns in the identities of the individuals who were the object of the jokes. A group of unhappily married men might be well stocked with humor reflecting negatively on wives. Another group might consistently denigrate recent immigrants, and so forth. Broadly speaking, there are two different constructs we might use this data to analyze.

On the one hand, this research might provide empirical data about the intentions and values of individuals. This might contribute to answering questions such as “What portion of salespeople in this formerly male-only occupation are prejudiced against female ‘salesmen’?” or “How do people feel about the recent influx of immigrants from Ethnia?” On the other hand, our research might not be about individual perceptions and intentions at all. Suppose a happily married, profeminist man started work with a group of older *salesmen* who bonded in their free time by telling jokes that reflected negatively on wives and family life. The new guy must choose between being untrue to his values on the one hand and risking being an outcast on the other. In this case, the misogyny of the work group may not even involve intentionality or self-consciousness on the part of those participating. It is structural. Our research interest might be the process of social construction through which misogynistic jokes are normalized as expected behavior and legitimated as inoffensive. This situation was not produced by the study’s participants, although they participate in perpetuating it. This is a structure preexisting, and largely independent of, their speech acts, one that they entered and one that can be studied as an entity in its own right.

### Application

Analogously, one might look at the discourse of “productivity and efficiency” in organizations, with its origins in large-scale industrialization and its present contradictions in emerging postindustrial economies. This is a theme researched discursively in Jacques’s *Manufacturing the Employee*, which seeks to discursively analyze the pernicious legacy of the industrial within the postindustrial

from a perspective indebted to Foucault. Similarly, one might study masculine bias within management discourse as did Joyce Fletcher by inquiring how the discursive system makes it easier to successfully speak of military and sport images than of more work-relevant feminized images related to nurturing, supporting, and communicating—even when these feminized qualities are precisely what is stated by management as being needed for organizational effectiveness.

The metaphor of text has not been limited to books, articles, and things commonly thought to be texts. Any systematically encoded practices can be read as texts. Verbal speech can be considered text. Street advertising, graffiti, signage, television, architecture, and more can be read. For instance, one might “read” particular forms of music videos, such as gansta rap, in order to determine the structure of that particular language in terms of its symbols and meta-messages structuring what can be said. What can be said, for instance, regarding the appropriate role of women (be a “ho” or a “bitch”) or the meaning of success (“bling,” coercive “gangsta” power). This constitutes a language in the sense that a music video producer can—and must—work with a specific vocabulary of symbols whose meanings are already familiar to speakers of this language: viewers. If these symbols are combined according to the rules of the language, they produce intelligible meanings. If they are not, they either produce unintended meanings or they are simply unintelligible. Even subversion of the rules, ironically, demands observance of the rules.

For instance, the 1998 video *Pretty Fly (For a White Guy)* by the Offspring, places a clueless, white suburban male at the center of an otherwise-expected language of rap video symbols, the gangstas, the guns, the bling, the women tricked out as bitches and ho’s. With just the one symbol subverted—a rapper who is nerdy rather than cool/threatening—but leaving the language otherwise intact, the video is made humorous.

In contrast, imagine trying to make a rap video encouraging young men to embrace Islam; dress conservatively; treat themselves and women continently; abstain from alcohol, drugs, and guns; and devote time to spiritual study and bettering the community. There is no music video language for this message. There are heavy metal videos, rap videos, and rock chick videos, all with their own

dialect of the language, but there is no vocabulary within this language for representing Islam. One can do a video for the rock band Shihad, but spiritual *shihad* is unrepresentable, except as foolish. To communicate that message, one would have to either fit Islam into the lexicon of music video language (at the expense of the message), or one would have to get that language community to learn another language. This is done, for instance, by outreach programs such as San Francisco’s Black Muslim Bakeries, where people are drawn for the food but through this interaction have an opportunity to observe reality interpreted through a different language—the discourse of Islam—within which it is the vocabulary of the music video that is unrepresentable, except as degenerate.

### Critical Summary

It is quite important at the present time to question whether the object of discourse analysis (or discursive analysis) is the speech act or the linguistic structure determining which speech acts are meaningful, because they are two different objects, and it is common for authors to fail to specify which they are studying. This potential confusion is compounded by a growing trend to call one’s analysis discursive when it is grounded in methods and techniques that used to be called interpretive, ethnographic, narratological, or dramaturgic. Given the very broad set of meanings the term *discourse* has had, this labeling cannot be termed incorrect, but it is confusing and can be misleading. Within organizational studies, for example, most of the researchers who have worked under these headings have concentrated on the intentionality of individuals or groups, not on the structural conditions underlying those speech acts. Such work has not introduced methodological or theoretical innovations but has simply attached a more fashionable (albeit less informative) name to an established approach. To further complicate the matter, these approaches *can* be used as a basis for structural analysis, such as that of the anthropologist Claude Lévi-Strauss, so one cannot create a neat correspondence between theoretical position and method.

At present, one can assume only that research claiming to be discursive will, in some way, work with the metaphor of text. Beyond that, one cannot assume any specific methodology, epistemology, or

object of analysis, because these are subject to variation. This is a problem only if one assumes discourse to be a discrete theoretical or methodological position, which it is not. Like *qualitative research*, *discourse analysis* is a term applied to heterogeneous positions that appear incoherent if lumped together but that constitute several distinct clusters of coherency if studied in their own right.

## DISCOURSE ETHICS

---

Discourse ethics, as Jürgen Habermas himself puts it, is a “discourse theory of morality” that defends the primacy of the “just” over the “good.”

It provides a procedural explanation of the moral point of view and how moral norms may be justified on the basis of reasoned discussion, argument, and agreement among participants in practical discourses.

### Conceptual Overview and Discussion

Discourse ethics arises out of Habermas’s application of his *theory of communicative action*, in particular the validity claim of *normative rightness*, to moral theory and moral philosophy. Discourses, which address problematic validity claims, represent a reflective form of *communicative action*. All moralities are viewed as revolving around ideas of equality of respect, solidarity, and the common good, and such ideas can be reduced to the symmetrical and reciprocal relations presupposed in communicative action. In everyday communicative action within a particular lifeworld it is not necessary to extend the presuppositions about symmetry and reciprocity to people external to or not belonging to such a lifeworld. However, because lifeworlds exist in the plural, an extension into universality becomes necessary when argumentation on moral norms is at issue. Habermas distinguishes among three kinds of practical questions—pragmatic, ethical, and moral—but only issues of the right or of the just regulation of social interactions are subject to universally valid argumentation, agreement, and consensual regulation. Ethical questions (e.g., who we are, who I want to be), questions of the good, cannot be abstracted from specific ideas of identity and the good life within particular lifeworlds and traditions. This focus on the moral sphere as coextensive with questions of justice excludes much that is at present understood under the term *ethics*.

The project of discourse ethics has been assisted by Habermas’s early collaboration with Karl-Otto Apel on the idea of an “ideal community of communication.” This allows for a reformulation of the monologic nature of Kantian ethics by grounding moral norms in dialogic communication. As participants in argumentation, viewed as a problem-solving procedure that generates convictions, we are all on our own yet simultaneously embedded within a communication context. Immanuel Kant’s categorical imperative—“Act only according to that maxim by which you can at the same time will that

it should become a universal law”—is replaced by a procedure of moral argumentation, combining the *discourse principle* (D) and the *universalization principle* (U).

The principle of discourse ethics (D) states that only those norms can claim to be valid that meet, or could meet, with the consent of all people affected in their capacity as participants in a practical discourse. Ideal conditions of such practical discourse can never be fully realized, and Habermas has now moved some distance from his earlier outline of the ideal speech situation, but the idea of consensus under ideal conditions has concrete practical implications in that participants engaged in a cooperative search for normative rightness or the just in any given contested situation must assume that such conditions are met to a reasonable degree. For this to occur (U), the universalization principle must hold, and such conditions are not met unless all affected can freely accept the consequences and the side effects that the general observance of a controversial norm can be anticipated to have for the satisfaction of the interests of each individual and that these consequences are preferred to those of known alternative possibilities for regulation. In practical discourse U acts as a rule of argumentation and is grounded in the presuppositions of argumentation in that anyone who attempts to discursively redeem normative claims to validity intuitively accepts such procedural conditions. Apel notes that this insight was unavailable to those following the philosophy of the subject (e.g., Kant) in that the uncircumventable “I think” (“Cogito”) is not now to be understood as something transcendently isolated and autarkic (as portrayed, e.g., in Rodin’s *The Thinker*) that could never become part of language but must always and already be understood as “I argue in a discourse.” One argues in practical discourses as a participant who belongs simultaneously to a local and an ideal communication community of Others.

Agreements made possible by discourse ethics depend on two things: (1) a person’s right to say “Yes” or “No” to validity claims, as in communicative action, and (2) overcoming the egocentric viewpoint. People are individuated through processes of socialization and moral theories must solve two tasks simultaneously: (1) the inviolability of and respect for each individual related to autonomy and freedom and (2) protection of the

web of intersubjective relations of mutual recognition to which correspond the principles of justice and solidarity, respectively. Both principles have the same root: the vulnerability and exposedness of the human being linked to the insecure and fragile nature of personal identity that cannot be maintained in splendid isolation. It follows that the idea of autonomy becomes intersubjective in that the free actualization of one person’s individuality depends on the actualization of freedom for all.

Discourse ethics, notwithstanding its sustained critique of individual reflection, remains in the tradition of Kantian moral philosophy in that it is deontological, cognitivist, formalist, and universalist. Kant dealt only with problems of right or just action, not with all the problems of the good life as in classical moral philosophies. The phenomenon to be explained, in terms of moral philosophy, is the normative validity of commands and norms of action—which a deontological ethics conceives as analogous with the truth of assertoric statements. This positions discourse ethics as a cognitivist ethics that answers the question of how to justify moral norms. Formalist ethical theories provide some rule or procedure that explains how something is to be looked at from the moral point of view; one could, for example, refer to John Rawls’s “original position” or George Herbert Mead’s “ideal role taking.” Kant’s categorical imperative acts as a principle of justification that distinguishes between valid and invalid norms in terms of their universalizability. Discourse ethics remains formalist in replacing the categorical imperative with the discourse principle (D) that provides only a procedure, practical discourse, but no substantive guidelines. Finally, discourse ethics remains universalist, and critical modernist, because it retains the central intent of Kant’s categorical imperative within the principle of universalization (U).

### Application

Discourse ethics is grounded in argumentation; hence it is open to empirical investigation. Since the publication in English of *Moral Consciousness and Communicative Action* in 1990 and *Justification and Application—Remarks on Discourse Ethics* in 1993 and its influence on subsequent major works on democracy, political theory, law, religion, political economy, and cosmopolitanism, much theoretical

debate has occurred among theorists of morality, ethics, religion, justice, democracy, globalization, communications, politics, political economy, and law. Empirical work is in its infancy, but if the appropriation of Habermas's earlier work on communicative action by scholars in the social sciences is any guide then the range of possible applications of discourse ethics to substantive issues in a globalized world is vast.

One recent example is Rebecca J. Meisenbach's application of discourse ethics in exploring organizational communication in a case study of the American Red Cross's (ARC) handling of its Liberty Fund. This fund was created after the September 2001 attacks on the United States. Donations poured in, but questions almost immediately arose as to how such donations were to be used. In late October, the CEO who initiated the Liberty Fund (which had received over \$500 million at that stage) resigned amid rising negative publicity, including a subcommittee meeting of the U.S. House of Representatives, as the public and donors claimed they had been misled about who were to be the recipients of the fund; that is, victims and families of victims of the September attacks or other ARC clients. Meisenbach subjects various definitions and conflicting interpretations of ARC communications to critical analysis by identifying validity claims in terms of discourse ethics and by determining who could possibly be affected by drawing on the universalization principle (U). The "monologically" created Liberty Fund is contrasted with the non-ARC-related September 11 Fund; the latter viewed as responding to problems and donor concerns much more quickly, dialogically, and openly than the former. Moral rightness and justice are placed here at the center of case study research and are shown to be capable of providing both an explanation of how such organizational difficulties arose and, perhaps most interestingly, how they could have been avoided.

### Critical Summary

Discourse ethics draws on two key assumptions: (1) that normative validity claims have cognitive meaning and that they can be treated in a manner analogous to truth claims and (2) that justification of moral norms or commands requires that a real

practical intersubjective discourse takes place in contrast to the monological form of Kant's categorical imperative. Grounded in argumentation, many avenues of empirical investigation from the methodological perspectives of participant, virtual participant, and observer are possible in diverse fields.

## DISCURSIVE FRAME

---

Defining *discursive frame* requires an examination of each term. In a narrow definition, *discourse* is the sum of a conversation, or speech, or some other unit of language communication. More commonly in academic use, discourse is conceptualized as originally defined by French social theorist Michel Foucault. Foucault focused on communication and meaning within a societal group and sees that a particular communication and meaning system is created within the group by objects, ritual, and the privileged: what the members of the particular group can talk about, where and how they can talk about it, and who can do the talking. With these limitations on the particular group culture, a discourse evolves as a system of thought reflexively created with particular ideas and beliefs, actions and practices, attitudes and preferences, and the subjects and worlds

these systematically construct. Discourse is assumed to belong to or at least reflect a group or segment of society and is significant both by what is said and what is not said. Consequently, one commonly hears references to *feminist discourses*, or *liberal discourses*, or *postcolonial discourses*, or *racialized discourses*.

Within a particular discourse participants can make choices, sometimes subconsciously and sometimes strategically, about how to “hear” something or how to “say” something. This can be called *framing*. Erving Goffman set the foundation for current sociological and media concepts of framing with his position that unconsciously developed cognitive schemas or structures shape the way individuals perceive and represent reality. These frames, or cognitive perceptual structures, develop through communicative processes.

### Conceptual Overview and Discussion

George Lakoff and Evan Frisch pointed to an instance of very specific strategic framing of discourse, namely, the choice by the Bush administration following the events of September 11, 2001, in the United States. The event was at first called a *crime*, and a narrative and response strategy could have been created on the basis of the crime frame. However, the Bush administration consciously rejected the crime frame and chose to use instead a war metaphor: the “War on Terror.” A *frame* in this perspective refers to the packaging of a rhetorical message in a way that particular responses will be encouraged and others discouraged.

*Discursive frame* can be looked at as “framing discourse,” as in the case of the response to the attacks on the World Trade Center and the Pentagon on September 11, 2001. Within the already-particular and limited discourse of American political rhetoric, a specific choice was made to frame the response in a certain way. In the music research example provided in the next section, elite performers seemed to use a selective frame within the unique discourse of music.

### Application

A characteristic of case study research is inherent in its name: The focus is on a case. Often the specific case involves a group of people constituted in a

particular way that makes it qualify as a case. Given what has been said about discourse and about framing, it is logical to assume that in many cases there will be a unique discursive frame. This means that the case study researcher needs to be taking discourse into account in the research.

For example, if a researcher were to construct a case study within a university department, knowledge of the discourse frame of the department might be crucial to certain questions, as evidenced in the following true incident. A few years ago, a professor was offered a position in a university, and while he was making plans to purchase a house and relocate his family he was asked to present a lecture that he was doing on a university tour. The lecture, duly delivered, presented a position critical of a major donor to the department. Within 2 days, the offer of the position was revoked. When asked whether the donor had put pressure on the administration, the answer was “There was no communication with the donor.” There did not have to be. The discursive frame within the department did not allow discourse critical of the donor. Everyone “inside” knew that and responded without any overt complaint from the donor. The department had created subjects and worlds in manner described by Foucault.

There are two ways discursive frame can enter the research. The first is as a possible barrier to in-depth interview responses. The discursive frame limits what participants may tell you in conversation or interview, and a researcher may need specific strategies to breach the discursive frame and allow the interviewee to speak the unspeakable, to acknowledge denied perspectives or experiences, and to shape interpretations critical of dominant discourse. This was illustrated in the research of Linda Cameron and Lee Bartel.

Cameron and Bartel undertook a research study examining the conditions of learning for musicians. Asking for written, anonymous, personal narratives of memorable experiences with music teachers, they discovered that many people had negative experiences with lasting effects. When Bartel and Cameron began a second study involving interviews with elite performance teachers, they encountered what seemed to be a unified positive narrative about how wonderful music is and how rewarding it is to be a musician. No one talked about tyrannical conductors; or egotistical,

abusive teachers; or the psychological hardship of thousands of hours of solitary practice. What they encountered was the discursive frame of music education.

The second place for discursive frame is a methodological one, as discourse analysis or frame analysis to explore the discourse itself. For example, Maura Kelly described analysis of discursive frame in her research of teenage sexuality discourse. She started with the premise that her interviewees would use three metaphors (gift, stigma, and process) related to virginity loss and that these metaphors were products of specific discursive frames. Her research then defined these research frames as (a) abstinence—the discourse that constructs teen sex as immoral; (b) urgency—the discourse that constructs sex as a pleasurable activity and as essential to the consolidation of gendered identity; and (c) management—discourse focused on the management of risk (physical, social, and emotional), especially with regard to contraception.

Furthermore, to analyze discursive frame is to put the discourse into a context, to compare it with other, related discourses. As well, focus can be placed on a specific discourse community—perhaps as a case itself—of which a person is a member. A person may well be a member of several discourse communities and move among them quite consciously—effortlessly or with difficulty.

### Critical Summary

Given the prominence and dominance of the text, spoken and written, in qualitative research, discourse awareness and discursive framing must be considered an important methodological and procedural dimension. It also has the possibility of being a highly productive analytic lens.

## DISSERTATION PROPOSAL

---

A dissertation proposal is a plan and the means by which a student systematically documents why a research problem is worth investigating and how that can be done appropriately for completing a dissertation. Most universities in the Western world require a research dissertation or thesis proposal to be submitted for approval if a student is enrolled in a graduate research-based degree. That degree may have a coursework component as well as a requirement to complete a dissertation. In some instances, the degree has a research-only requirement. Some universities require a proposal to be approved before a student's enrollment is confirmed. An approved proposal ultimately is a foundation document for the dissertation-level

research. In what follows, important aspects of a dissertation proposal for case study research are considered.

### Conceptual Overview and Discussion

A dissertation proposal outlines key elements of the student's proposed research from its inception until the production of the final dissertation draft, which will ultimately be submitted for examination. The student is making, in his or her proposal, an underlying argument about a research problem or issue. Until a proposal is formally accepted by the university, the student is usually not able to begin work on any field, laboratory, or clinic-based research that will form the basis of his or her dissertation.

Just as there are numerous ways to conduct sound research, there are many approaches to proposal writing. Most universities offer general guidelines for doing so that are augmented by specific requirements from each of the faculties. To be sure, there is no universally accepted way of developing a research proposal. Developing a sound dissertation proposal may take successive revisions that, although initially time consuming, may produce a better study and save time over the course of the research. It is not unusual for some students to have to resubmit a proposal a few times before the proposal is accepted. Expectations about the design and contents of a dissertation proposal are usually set out explicitly and implicitly by each university or by individual faculties. For example, there may be a requirement that the proposal not exceed 20 pages in length. There also may be a non-negotiable expectation about a research writing style or referencing system, for example, American Psychological Association style. By contrast, students may be encouraged to select or adapt a proposal format from a range found in the literature. Decisions about the format of a proposal are influenced by the purposes, nature, and design of the research that is to be attempted. Sometimes, the format of a student's dissertation proposal is very similar to what the first final dissertation's few chapters will ultimately be. The final format of a student's dissertation proposal is likely to be determined after deliberations with the supervisor and supervisory team.

Even if a student's dissertation proposal has been formally accepted and endorsed by a faculty, it does not contain or allow for every part of the

research that is to follow. Nonetheless, the proposal acts as a common reference point for both student and supervisor(s) to refer to over time. In that regard, a dissertation proposal provides a documented "organizational memory" of what was formally agreed to by all relevant parties. Because the proposal may also be used as a form of a working and moral contract between a student and the supervisor(s) over several years, it is important that it outline, for example, a clearly defined argument, explicit theoretical perspectives, justified research design, anticipated costs, and a time schedule. Importantly, the contents of the proposal need to show that the research will be feasible and able to be done in a scholarly manner by the student. Both the proposal and, in particular, the research, should be able to withstand rigorous scrutiny from scholars in the field.

### Case Study Proposals

Undertaking case study research is often exciting and challenging. On the one hand, it usually provides a dissertation student with numerous opportunities to directly understand a complex, delineated, and contemporary phenomenon in its naturalistic setting. On the other hand, it requires considerable effort and discipline, if the case study is to be evidence based and done well.

Because increasing numbers of students throughout the world are undertaking research-based graduate degrees while maintaining full-time jobs, case study in particular may be a viable research strategy for many to consider. Oftentimes, case study can require less time for field work than, for example, ethnographic research. That does not mean case study research requires less time overall than other forms of research; however, this time prospect may prove attractive to dissertation students who are more easily able to study after work hours and less able to get extended time off from their jobs to undertake field work. In this regard, case study is potentially a highly flexible research strategy for the 21st century, especially given the emphasis on life-long learning and organizational learning. Of course, as with all dissertation-level studies, there is an expectation that the quality of the case study research process and outcomes will be significant. Poorly designed and executed case studies can diminish the standing of this type of research.

### Application

There are countless ways in which a student learns about the nature of case studies and how to design, conduct, analyze, and report on this form of research. Early on in the process, one way to heighten the prospects of case study research being sound is by using an evidence base to inform the dissertation proposal writing. Preparation and write-up considerations for a proposal vary considerably depending on the nature of the case study research that is ultimately to be undertaken. It is important that a student's epistemological, ontological, and methodological assumptions are acknowledged in a proposal. As well, the theoretical framework that underpins the proposed case study usually needs to be apparent. The research paradigm in which the student will be situated when undertaking the case study should also be nominated. It is important to be explicit about these elements, because the net effect of a student's way of viewing the world, reality, and what constitutes knowledge influences what is ultimately selected for investigation. A student's research standpoints also shape how the case study is conducted, analyzed, and interpreted.

A proposal that involves only a qualitative case study will be different in some ways from a quantitative case study proposal (see examples given in the following paragraphs). A mixed-method case study proposal will likely adapt aspects from both qualitative and quantitative research domains.

#### *Example 1: Components of a Qualitative Dissertation Proposal*

Introduction: background, the problem, purpose, aims, theoretical and conceptual frameworks, study's questions, unit of analysis, potential significance, definition of terms, limitations, delimitations. Literature review, Methodology: justification for design and methods, field setting, sample, ethical protocols, data gathering methods (interviews, document appraisals, observations), trustworthiness, validity, reliability, triangulation, data analysis, timeline schedule, budget. Conclusion, References, Appendices: ethics applications, ethics approval letters, sample letters of invitation, semistructured interview guide, observation rubric.

#### *Example 2: Components of a Quantitative Dissertation Proposal*

Introduction: background, purpose, aims, problem statement, research question and hypotheses, unit of analysis, significance, definition of terms. Literature review, Methodology: design, theoretical stance, instruments, sample and selection of sample, statistics, ethical considerations, procedures, data analysis, time frame, budget. Appendices: ethics applications, questionnaire.

Ideally, a proposal should show that the student has a detailed grasp of the sequencing and organizing involved in any field work component of the case study. This includes having an understanding of ethical ways of conducting research, knowing how to perform document analyses, interviewing and observing participants, and developing a system for participant checking of tentative findings.

As Robert Yin has long identified, explanatory and exploratory case studies have the potential to produce theory. This is likely to render those types of case study very attractive to dissertation students if there is an expectation that a study should add knowledge to a field. Undertaking a descriptive case study may be inappropriate at a dissertation level because of the inability to develop theory from such research.

In the social sciences, qualitative case studies that are undertaken from an interpretivist researcher stance are increasingly common. As many of Sharan Merriam's case studies show, these investigations seek to identify meanings that participants have about a context, event, individual, group, or phenomenon. In this paradigm, the researcher analyzes triangulated data inductively to create rich insights that reveal a deep understanding of the unit of analysis within the context in which it exists.

Unlike some types of research, case study can be developed by researchers from disparate paradigms. Ideally, judgments about the clarity, trustworthiness, and ethical nature of a case study proposal will be formed in light of relevant evidence. For example, what may count as trustworthiness in an interpretive qualitative case study is not likely to be suitable in a positivist-informed quantitative case study. How, and the extent to which, validity and reliability within each of these case studies are achieved is likely to differ.

### Critical Summary

In effect, a proposal offers an argument to convince scholars about the usefulness and viability of the intended research. It is expected that the logic that underpins the proposal is an outcome of thorough preparation by the student. The proposal should show that the student has understood and chosen a theoretical framework, design, and methods that cohere to enable a credible, significant, and fascinating case study to be produced.

## DOCILE BODIES

---

The term *docile bodies* was developed by French social theorist Michel Foucault in his book *Discipline and Punish* to help understand a shift in the way that power was exercised over subjects/citizens beginning at the end of the 17th century. Instead of a violent taming of what might be called the “wild body” of the deviant, institutions and practices of social control undertook practices aimed at observing, documenting, and cultivating reflective, penitent, and, most important, self-regulating subjects.

### Conceptual Overview and Discussion

Foucault’s *Discipline and Punish* is fundamentally an account of the way power shifted in the 17th and 18th centuries away from the external discipline of the body (e.g., torture) toward various forms of internal discipline that involve the compliance and active participation of the subject. Foucault’s account begins with a case study description of the torture of the criminal Robert-François Damiens to illustrate the apparent brutality and ultimately depict the strangeness of these kinds of practices to the modern reader. He then goes on to show how the relatively rapid movement away from these kinds of disciplinary practices toward those of the regulated life is characterized by the 19th-century prison. In other words, the development of humane institutions” had less to do with softening the treatment of deviance than with the efficiency and effectiveness of compelling the deviant to develop what Hans Gerth and C. Wright Mills called “internal whips.”

There has been considerable misunderstanding of what Foucault meant by *docile body*. Often this is interpreted to mean that bodies are constrained and restrained in contemporary prisons through a kind of brainwashing. This critique misses the central point that the docile body is a productive body in the sense that it is carefully taught how to appear and how to behave rather than being left in what might be considered a “wild” state only to be brutalized when it gives offense to power. The production of the docile body in Foucault’s analysis is not a body that does not move or that is inactive in any real sense; instead, the docile body is one that is under the control of its possessor in alignment with norms and more or less subtle forms of regulation that are learned and developed through training rather than through the application of external force. The idea of *biopower*, or control of the body, refers to those knowledges, practices, and training regimens that educate the subject about how to appear and act.

The docile body is not marked, broken, or brutalized; in fact, it is the intact and healthy appearance of the body that has become an embodiment of an important sign of the power of regulation. Indeed, the regulated body takes on the appearance of what we have come to call “healthy” to the extent that regulated bodies are understood as representing the way that people are naturally supposed to be. The regulative moves that have

produced this body are thus obscured as regulation and assigned to nature. Power, then, is applied in multiple and subtle ways by the acting subject rather than through external means of control that Foucault exemplified in his discussion of torture. We come to desire self-regulation, for example, in exercise regimens, health literature and discourses, or through reading gendered men's and women's magazines. Although in *Discipline and Punish* Foucault used the idea of "normalization" to describe this general phenomenon of control, he later called this disciplinary power by the name of *biopower*. Biopower, then, marks an important shift from the application of restrictive force to the production of a reflective self. Power, then, is productive, multiple, and situational rather than coercive, uniform, and centralized. Knowledgeable subjects internalize and reproduce through disciplined, thoughtful, practice constructions of the self that themselves reflect knowledge about what is proper, correct, educated, sophisticated, and sane.

One of Foucault's most important contributions to social thought is the way in which he has demonstrated how conceptions of each of these categories of civility, decorum, propriety, and health are generated discursively as containers of power. He did this by documenting the rise of new 18th-century institutions such as prisons, modern schools and hospitals, and asylums as spaces in which individuals could be grouped not for control and repression (although his accounts never sugar-coat the repressive foundation of these institutions) but instead for "correct training" and internalized discipline. Because of its focus on the multiple ways that power is enacted and negotiated, Foucault's work has generated renewed interest in the social sciences and humanities in microanalysis and in the power of case studies to illustrate the mundane production of power by ordinary social actors.

### Application

Training and surveillance were essential to the process of correct training and the production of docile bodies. Although the routines of institutional discipline were key preoccupations in his early work, Foucault was also very interested in the way that power is spatialized. The architectural technology of Bentham's *panopticon* served as the principal physical means through which the docile body might be produced and monitored. In this ideal type

architecture of control, the inmate of the prison was removed from the isolation of the dungeon and placed within the well-lit, totally visible cell. Each cell in the panopticon was oriented in a circular pattern around the central guard house in such a way that a single guard could see every part of each individual cell. The body of the prisoner was therefore on display at all times and available for assessment and correction. The ideal prison was renamed *penitentiary*, a place of penitence where the inmate would be taught to reflect and to develop a personal understanding of correct behavior and, most important, to adopt the attitude that it is his or her responsibility to understand and improve. The ultimate goal is an intuitive normative understanding, not the memorization of rules. This, in a sense, sets the tone for future humanistic developments such as progressive education that understands children as knowledge constructors rather than as receptors, or contemporary visions of proactive healthcare as the responsibility of each person. Foucault saw each of these as yet another instance of biopower.

These modern institutions also provided study spaces for nascent disciplines and their aligned professional practices, such as psychiatry, psychology, pedagogy, criminology, and social work, to come to know their subjects and generate new and deeper knowledge about them. In this way the disciplines of the human sciences came to construct a vision of humanity while at the same time mapping the multiple ways that individual social actors could deviate from the idealized human condition.

The new locus of power was thus in the body of the prisoner rather than in the instruments of physical violence, restraint, and physical control. Rather than disabling the body through external violence, the body would be controlled from within. In this sense Foucault's work fits in with the work of other social historians, such as the Marxist E. P. Thompson, who studied the cultural changes that were associated with the transition to market capitalism in Europe. Within the context of a modern society in which coordinated, productive activity was at the center of the industrial complex, education, broadly understood, became essential to the development of a labor force that could be counted on to work regular hours and in tandem with other participants in, for example, factories. The training of the body to work repetitively, automatically, and accurately became an important component of industrial production and prog-

ress. It was also crucial to the production of the modern democratic citizen, whose choices and agency needed to be brought within limits and set toward coordinated ends.

The main difference between Foucault and Marxists in their examination of the production of the docile, or disciplined laboring body is the way Foucault conceptualized ideological mechanisms as the locus of power. He saw the production of knowledge as central to social production and reproduction more generally. Foucault paid little attention to the way that large-scale economic forces operate in social space. This opposed the Marxist-inspired vision of the fundamental or infrastructural importance of material forces of production which themselves generate ideological forms.

In his later work Foucault became more interested in everyday life practices and the way that power worked as a productive force to delimit and conceptualize core features of modern self-production. There is an obvious connection here between the proliferation of discourses around the production of the self, the multiple locations in which self work is done (from prisons and schools to shopping malls, gyms, and spas), and the need for specific micro-case studies of how power works as a distributed and differentiated rather than a centralized phenomenon. This interest in biopower moved in two directions: (1) toward the constitution and regulation of populations (governmentality) and, simultaneously, (2) toward the intimate self-governance. His interest in biopolitics shifted from the institutional regulation of deviance toward the discursive production of desire and what he called the “care of the self.” This marked a more fundamental shift inward as Foucault investigated the terrain of normalized human conduct and the persistent resistance that shapes and reshapes discourse around sexuality, intimacy, and self-understanding.

The focus, then, is on the more contemporary preoccupation with the production of the body as an object of desire, experience, and cultivation. This shift parallels the transition from the institutional density and power of the state and the productive enterprise (industrial capitalism) that began in the latter part of the 19th century toward the importance of information, the mass media, network society, and other contemporary change forces placed under the rubric of the knowledge society. This general approach to social analysis

has been enormously influential in recent decades in a variety of spaces. For instance, Mark Poster analyzed the way that Foucault’s work can support understandings of emerging information technologies and the way in which knowledge is a principal instrument of power. Another example is found in the work of urban sociologist Manuel Castells, who has developed a detailed and profound analysis of the way that self-production and identity questions have come to assume a critical importance in contemporary societies.

### Critical Summary

In the end, Foucault saw no clear escape from the inevitable play of forces and ideas that institute power at the very center of all social life. Every utopia, every solution, becomes yet another vision that constructs an idealized picture of human nature or correct conduct and at the same time a new set of others, monsters, criminals, and deviants. The idea that power can and should be seen as a productive social mechanism was revolutionary, and it marked an important turning point in historical studies toward microanalysis and social histories of the details of everyday life and mundane institutional practices. Fundamentally, the body is the location of power, and Foucault’s concept of the docile body represents one of the first and most influential ways of theorizing the ways in which biopower operates.

An important methodological implication of Foucault’s work as well as the work of other poststructural theorists is the idea that structural explanations of social institutions and processes are inherently oppressive. Because of this attention to microsituations we see the way that power operates, not as a structural foreclosure but rather as a dynamic process of dominant strategy and resistance tactics. In this sense, Foucault’s own broadly conceived case studies of prisons, asylums, and hospitals demonstrate how the docile body is never perfectly produced. As he pointed out in an interview in which he used the extreme example of the Nazi concentration camps, resistance is always present and always possible, even in the most oppressive social conditions.

## DOCUMENT ANALYSIS

---

Documents, as a record of human activity, provide a valuable source of data in case study research. Along with interviews and observations, they comprise one of the main forms of data sources for interpretation and analysis in case study research. Document analysis can provide a window into a variety of historical, political, social, economic, and personal dimensions of the case beyond the immediacy of interviews and observations.

### Conceptual Overview and Discussion

Documents can include a wide variety of materials relevant to the case under study. In Sharan Merriam's view, documents comprise a variety of written, visual, and physical material, including any artifacts that can shed light on the case. In this view, documents are by-products of human activity that "document" their activity over time. Because these documents have been created through ongoing day-to-day activities unrelated to the present research they can provide authentic records that shed light on multiple facets of the case and can provide clues that may be useful in framing interview questions and observation protocols. Documents can be categorized into three main types: (1) public records, (2) personal documents,

and (3) physical materials. A fourth category of documents are those created by the researcher, such as field notes and a research journal. Many of these documents may be created and/or stored in an electronic environment.

Although at times there is a clear distinction between public and private documents, at other times the line between them is quite blurred, creating a continuum from completely public, to semi-public, to semi-private, to completely private. Personal documents can now be found anywhere along this continuum. With burgeoning online venues such as personal Web pages, Facebook, and numerous blogs, the personal easily becomes available to the public. Traditional public records include anything that is available for public use, although some of these are more readily available to the public than others. These documents include (but are not limited to) census data; newspaper articles and archives, maps; court documents; wills; company and government policy documents; manuals; handbooks; photographs; magazines; books; brochures; and advertisements, from billboards, to flyers, to television commercials. The myriad range of public documents available requires creativity on the part of the researcher in identifying which might be most relevant to the particular case. Along with researcher creativity, research participants can point to valuable documents the researcher might not have thought of, especially those that are not completely public. Thus, whereas documents can help lead to good interview questions, interviews can also lead to new document sources. This category could include semi-public documents, such as employee contracts, manuals and policy handbooks, minutes, payroll lists, health records, and so on, to leads on personal documents, such as photo collections, family histories, diaries, letters, scrapbooks, videos, and other electronically stored family or individual records. This category of documents, by representing accounts created by individuals or particular interest groups or organizations, can provide valuable perspectives on the case that likely will not be found in documents originally created for the general public. Finally, artifacts and physical traces as documentation of human activity can provide rich data sources to analyze.

Document analysis begins as documents are identified and/or selected on the basis of their

usefulness or relevance as data for the particular research. A parallel step is to validate the source and authenticity of the chosen documents. Knowing the source of documents enables the researcher to determine their likely purpose or intent as well as determine the perspective from which they were created. Merriam suggested several questions researchers might ask about the authenticity of a document:

- What is the history of the document?
- Is the document complete, as originally constructed?
- If the document is genuine, under what circumstances and for what purpose was it produced?
- What were the maker's sources of information? Does the document represent an eyewitness account, a secondhand account, a reconstruction of an event long prior to the writing, an interpretation?
- Do other documents exist that might shed additional light on the same story, event, project, program, context? If so, are they available, accessible? Who holds them?

Merriam comments on the importance of distinguishing between primary and secondary documents. *Primary documents* tend to be those created by people closest to the phenomenon under study. *Secondary documents* are those created by those not directly involved and perhaps at a later date. It is possible for a document to be either a primary or a secondary document depending on the purpose of the research. For example, a photographer's pictures could be primary documents in a study focused on the photographer but secondary documents if the objects or people in a photograph were the primary research focus. Once the selected documents are located and authenticated, they need to be copied and/or photographed. These copies of original documents can then be sorted into appropriate categories, and further analysis can be carried out.

Document analysis in terms of who has ready access to or who created which documents in a case can lead to insights about relationships among case participants, power structures, and communication patterns. Documents can be analyzed in terms of demographic and historical information

to provide background to a case. They can be compared for confirmatory or contradictory information that can illuminate new understandings or further questions to pursue. Content analysis, which has been a staple of document analysis, can take the form of highly structured searches that count the number of times particular words or phrases are used. Jonathan Hull described evaluation processes for computer programs designed to perform various document analysis functions on large volumes of data such as checks. The constant-comparative form of document analysis described by Robert Bogdan and Sari Biklen is a much more fluid search for themes or meanings that recur in a variety of documents leading to categories. Depending on the research focus, researchers may be searching for descriptive information, may do a comparative analysis of different perspectives from different sources, or may do a critical analysis that would uncover hidden sources of power.

### Application

Document analysis is a helpful research tool that can be used in as wide a variety of ways as a researcher has the imagination to create. A few examples are suggested here. A variety of documents, including such items as letters, sketchbooks, original artwork, and critics' reviews, could provide the total data source in a case study of the evolution of an individual artist or a particular art movement. A combination of public documents, such as newspaper accounts and public notices, could be compared with a variety of personal journals, photographs, and letters to tease out some of the contradictions and complexities of a particular case. Kelly Asmussen and John Creswell, in studying perceptions of campus safety after a gunman attack on campus, discovered an increase in newspaper advertisements for and registration in self-defense classes. Through records kept by the campus bookstore they identified increased sales of mace and whistles, and a sharp increase in cell phone purchases, especially by women, was noted. These documented changes, when compared with those before the gunman incident, pointed to a dramatic increase in safety concerns. A document such as a map or photograph could be used to stimulate interview

responses. A high school social studies teacher had students compare copies of high school yearbooks from 1948 up to the present day to examine shifts in the school community's gender and ethnic composition, shifts in the kinds of extracurricular activities, and shifts in various awards given, which can mirror changes in the surrounding community. A critical analysis of promotional brochures for an institution or business can lead to the identification of belief systems that may lie below the surface of espoused purposes.

### Critical Summary

Because they were originally created outside of the scope of the research, documents can provide a rich source of data pertaining to the day-to-day activities surrounding the case. Documents can also provide historical information that lead to a better understanding of the case in question and can provide a diverse wealth of information from a wide variety of sources. This wealth of possibilities creates several issues of which researchers need to be aware. Researchers need to be cognizant that because different documents were created for different purposes, they will present different points of view. To limit bias, researchers need to have a wide enough variety of documentary sources to provide a reliable research report. On the other hand, much of the documentary data may be irrelevant to the present research purpose, and the sheer volume of documentary data can become overwhelming. Thus, researchers using documents as a data source need to both broaden and narrow their scope, ensuring that they use documents that provide a rich variety of information focused on their particular research purpose.

## DOCUMENTATION AS EVIDENCE

---

*Documentation* refers to the variety of written, audio, and visual artifacts that exist within natural, nonlaboratory contexts before a research study is initiated. Documentation has traditionally been associated with historians, for whom it is the main source of evidence, next to oral history data. Qualitative researchers across diverse social science disciplines (e.g., anthropology, business, economics, education, political science, and sociology) also collect documentation, either when direct observation is not possible or as a supplement to direct observation.

### Conceptual Overview and Discussion

Documentation can be categorized as written, audio, or visual. Written documentation may include media or government reports; minutes, policies, or other procedural documents; letters; memos; and diaries. Documentation may also be auditory, consisting of interviews, videos, and radio and television scripts. Visual artifacts include photographs; maps; and material resources such as tools, instruments, and everyday utensils.

Documentation can be further classified according to accessibility and origins. *Open documentation* is accessible to the general public, usually through archival repositories or publications. Open documents may include correspondence, minutes of meetings, reports, and committee papers. In some cases, however, repositories may restrict conditions of access. Information from medical and personnel records is often protected by *restricted access* because they can present the researcher with ethical concerns. "Restricted" designations often require researchers to use pseudonyms or to aggregate findings to maintain individuals' privacy.

*Closed documentation* is usually accessible to only a small number of people who tend to be the originators of the material. This category pertains particularly to nonarchived items residing in familial collections.

Documentation can be categorized as official, personal, or popular culture with respect to origins. *Official documents* are generally produced by organizations for communications or record-keeping purposes. The most commonly recognized of these are research and discussion papers published by the organization as well as day-to-day correspondence (memos, letters, files). These are usually easily accessible because they tend to be archived in repositories approximately two decades after their creation. For items that have not yet reached the 20-year mark, researchers are required to apply to the organization of origin for access under freedom of information legislation.

*Personal documentation* includes items generated for personal reasons (letters, diaries, family albums and genealogies). Such evidence is among the most difficult to obtain because it is privately owned. *Popular culture documents* are generally used for commercial purposes, including television and radio programming, such as commercials, photographs, and other objects. Obtaining access to these items requires compliance with relevant copyright laws. One of the key considerations when working with popular culture is to limit the vastness of the materials available to ensure they are manageable yet still representative.

For qualitative researchers, there are many advantages to collecting documentation as evidence. Most important, documentation enables the researcher to examine phenomena in naturally occurring, contextualized settings. Documentation can be transported and/or copied, facilitating analysis and the production of enduring records. One of the difficulties of undertaking research in which data are generated (e.g., surveys and experiments) is the potential impact of the researcher on a study's participants. Researchers working with existing (pre-study) documentation avoid the possibility of overly influencing a study's participants.

All research methods present researchers with both advantages and disadvantages, and documentary evidence is no exception. Documentation becomes problematic when the researcher is able

to uncover only partial evidence because of a failure to preserve materials or a loss of items. Under these circumstances, researchers must work with tentative conclusions. As well, researchers working with documentation run the risk of not recognizing erroneous or biased information. Finally, the meaning of any documentation is rooted in context and is not always immediately apparent. Because the researcher's interpretation renders material meaningful, it is important to ascertain whether items are authentic, credible, representative, and meaningful.

### Application

To determine *authenticity*, the researcher must ask: Is the material genuine/original? Who created it? Where, when, and why was it created? Answers can be generated by comparing private and public manifestations of the same materials. For example, one might compare popular coverage of key World War II events with descriptions of the same events communicated in a personal diary.

*Credibility* refers to the accuracy of the document. Has it been tampered with or modified? Is the object representative of the time it was created? Is it likely the language, clothing, or architecture belong to the alleged era of origin? Is an intra-office memo plausible, given organizational contexts and agendas of the day?

Researchers working with documentation also face the dilemma of whether evidence is particular to a single social setting or is *representative* of a larger context. For example, can one conclude that career aspirations of young adults in a school-to-work transition program in economically depressed regions are representative of all young adults? In this regard, it is imperative that researchers consider a sample group's characteristics.

In determining the *meaning* of evidence, researchers deal with interpretation, which inevitably depends on a document's authenticity, credibility, and representativeness. Consider a researcher who is conducting a case study of an organization that has held an employee retreat. The agenda items and minutes include team-building exercises as well as proposals for reorganizing the institution. It would be unwise for the researcher to assume that the retreat and reorganization were held because of economic hardship reasons unless

other documents (e.g., financial statements) indicated financial urgency.

### Critical Summary

Documentation provides researchers with a range of contextualized, naturally occurring materials when direct observation is impossible or needs to be supplemented. Written, audio, or visual evidence derived from official, personal, or popular culture is used extensively by researchers across social science disciplines. Useful as it is, documentary evidence is not without drawbacks. The effective use of documentation as evidence depends on researchers' abilities to scrutinize the material and determine its authenticity, credibility, representativeness, and meaning.

case study research inasmuch as it calls attention to the complexities of meaning-making present within the various disciplines of the social sciences engaged in interpretive research. The concept is used to name interactions present between the text attributable to the research focus, topic, or participant and the text the researcher brings to the inquiry. These two contexts—the context of that which is being researched (often referred to as the *object of the research*) and the context of the researcher (often referred to as the *subject of the research*)—interact dialogically and co-inform one another within the research process.

### Conceptual Overview and Discussion

Although the term *double hermeneutic* is frequently attributed to sociologist Anthony Giddens, philosophical constructs upon which the concept is based echo back to Martin Heidegger's notion of *Dasein*—interpreted here as a form of presencing—that is, to the researcher's presence within the research process. The concept of the double hermeneutic was further developed through extensions and interpretations of Heidegger's work by German philosopher Hans-Georg Gadamer and by French narrativist Paul Ricoeur. More recent philosophical and methodological examinations of the double hermeneutic include the move toward a postpositivist era in the social sciences, which situates the researcher fully within the interpretive process and demands attention be paid by the researcher (and, by extension, the research design) to the dialogical relationships operating within the various disciplines of social science research. This demand for attention to the interconnected spheres—or circles—of meaning-making, in both design and interpretation of research, leads to an increased emphasis on reflexivity within the research process. Not to be confused with self-reflection—although self-reflection is one of the tools the researcher can use when grappling with tensions arising—*reflexivity* refers to an awareness of the discourses within which both the research and the researcher are embedded as well as to the ways in which the contexts of the research refer back, reflexively, to prior experiences and knowledge constructs. Thus, the double hermeneutic requires that the researcher tend to the dual, or double, meanings present at both the microlevels of research

---

## DOUBLE HERMENEUTIC

---

In the field of hermeneutics—that is, interpretation, or meaning making—the *double hermeneutic* is used to name a concomitant production of meaning and meaning-making within the research process. The double hermeneutic is present in all

design and the macrolevels of situating the research within a given social science community, be it anthropology, education, history, political science, sociology, or other.

### Application

When designing social science research it is important to consider that the parameters of the research context are not limited to the object of the research; instead, the research design also needs to tend to the situatedness of the researcher. Inquiry that acknowledges the presence of the double hermeneutic can use reflexivity to better grapple with the interactions of meaning-making present between subject and object, and in both the research design and in the interpretation of data.

By incorporating reflexivity in the research process researchers work to render explicit the effect of the double hermeneutic. However, there is a paradoxical element in both the double hermeneutic itself and in the reflexivity used to address it: Because both the effect and the means used to render the effect more explicit call on meaning-making within and through the researcher and the research process, one encounters a seemingly endless series of referral. In this, the paradox of endless referral creates a tension within the process of reflexivity and returns to name the effect upon which it operates, that is, the double hermeneutic itself.

### *An Example of the Double Hermeneutic at Work in Case Study Research*

The following example illustrates the presence, or effect, of the double hermeneutic using a fictitious sketch of a case study scenario in educational research:

A researcher (e.g., an ethnographer conducting a case study in an elementary school classroom) collects data relevant to a research participant (e.g., a child learning to read) through participant observation. Subsequent to collection, the data are analyzed by the researcher to identify themes relevant to the reading process (phonological awareness, use of cuing systems, emotional responses, etc.). The researcher then situates the identified themes within the current body of literature on reading and learning to read and, on the basis of interpretations of the data, uses the results of the

case study to generate questions for further inquiry. In this scenario the double hermeneutic requires that the researcher acknowledge not only the context being researched (a child learning to read) but also the research itself (the act of defining the process of a child learning to read through ethnographic research). Because reading and research present as both historical constructs and contingent agents within such an inquiry, the research participant (the child) is not a finite object of study; instead, the child is engaged in meaning-making, and this meaning-making produces data, which are subsequently used in meaning-making by the researcher. Because of the effect of the double hermeneutic, the researcher is similarly implicated, because the act of researching also contributes to the production of knowledge within the research context. Consequently, the presence of the researcher serves to alter the meaning-making of the researcher (the ethnographer) and the researched (the child) throughout the research process.

The researcher needs to take into account, therefore, the dialogical production of meaning within the research context. The effect of the double hermeneutic means the research context is not “meaning neutral”; instead, the researcher (an ethnographer, in this case) and the researched (a child learning to read, in this case) are both active participants in the production of knowledge and the interpretation of meaning. Because of the historical and contingent production of meanings inherent in the multiple layers of the inquiry, the double hermeneutic engages both the researched and the researcher in a continuous interpretation of meanings within and through the discourses within which the research is embedded.

### Critical Summary

The double hermeneutic is an effect found in the dialogical relationships between research and researcher within social science inquiry. The presence of the double hermeneutic creates an additional space of interpretation that is neither that which is being researched nor the researcher; instead, the double hermeneutic calls attention to the interaction and concomitant meaning-making therein. Reflexivity can be used to engage some of the tensions presented by the double hermeneutic but will itself contribute to a further commingling

of interpretation and meaning-making. The effect of the double hermeneutic reminds researchers to examine the discursive effects of a given research context, within which discourse and meaning-making are produced by both the context and by the researcher's interactions and interpretations of and with said context.

## DRAMATURGY

---

Through employing the metaphor of “life as theater,” dramaturgical sociology is concerned with how certain understandings of reality are negotiated, maintained, sustained, and negated through human interaction. In dramaturgy, the microlevel interactions, the acts performed by various actors and actresses, are what constitute the human experience and create, rather than signify, the social order.

### Conceptual Overview and Discussion

Because the task of dramaturgy is to understand social interactions, how people come to create meaning, and why people behave in certain ways, the relationship between dramaturgy and case study research is in congruence. Case study research

utilizes theoretical understandings to make sense of a particular event, situation, or narrative under inquiry. Dramaturgy, as a theoretical lens, blends with case study research efficaciously if the researcher is seeking to understand human behavior through a social constructionist viewpoint. From this perspective it is argued that humans are not construed as objects on which outside structural forces act but as empowered beings who create meaning and direct their destiny through encounters. For the dramaturgist, the common or shared reality between or among people *is* reality.

The concepts of dramaturgy were first introduced by Erving Goffman in his foundational work *The Presentation of Self in Everyday Life*. According to Goffman, people perform in their relationships with others through a process of monitoring of words and deeds, trying to control the information about themselves through masking some aspects and emphasizing others. An understanding of identity as fluid, dynamic, and agentic, rather than predetermined, passive, and stable, is essential to a dramaturgical approach.

Goffman's understanding of the self stems from George Mead's work *Mind, Self, and Society*, in which the self actively intervenes in the world and is created through social interaction rather than composed of an abstract essence. Dramaturgy shifts to a more radical view of identity in which identity comprises a series of masks of underneath which lies no distinct, “real” permanent countenance.

### Roles

The central focus of dramaturgy is on the encounter of people who utilize roles, scripts, stages, props, and costumes to influence their audience in an attempt to negotiate reality. The desire for ontological certainty as an existential aspect of the human condition fuels the process of negotiation whereby people seek to make sense of social reality. Particular understandings of social scenes become privileged or deprivileged over others as both actor and audience negotiate, assign meaning, and order reality. Goffman is clear that life itself cannot be reduced to theater. It is *not* simply theater, but it is *like* theater. The expressions, symbols, and aspects of drama illuminate the process of how realities and meanings come to be

constructed in relationships. The metaphor of theater and its theatrical concepts are tools for analysis rather than instrumentally based truth claims about reality itself.

People partake in acting out different roles within society and organizations. The concept of the role is one of the important aspects of the dramaturgical metaphor. *Role* pertains to the particular image that a person wants to convey to others. A university professor seeks to convey an image that lets her students know she is knowledgeable in her subject matter, authoritative, and legitimate. To fulfill this role, she must attend specialized training that likely involves obtaining a doctorate from an accredited university. This is to instill the impression on future students, colleagues, and other audiences that she is set apart from others because of her training. Although the training does provide invaluable information, it also has a secondary purpose, which is to aid in the perception of credibility and professionalism.

In some form or another, paid and unpaid organizational roles (e.g., mother, banker, soldier, minister) require certain cues to let the audience know which role the person is going to be enacting. The more authentic the performance, the more believable the proposed version of reality is to the audience. Actors and actresses dramatize their actions and behaviors in order to appear convincing and to evoke the appropriate impression. However, one individual's role alone cannot create the "show." In addition to the setting, props, and costumes, the efficacy of performances by the actors and actresses in terms of scripting is vital to the play's success.

### *Performances and Scripts*

The idea that metaphorical scripts exist that people act out implies a predeterminism, but this is antithetical in dramaturgy, which is rooted in an interpretivist paradigm. People are the authors of their scripts in their enacted role performances. Performances are the rule or code-governed activities that serve to influence the audience within an interaction. They are enacted in the context of what is deemed appropriate behavior in the setting. Performances are not always done solo, but often in concert with other like-minded actors playing the same role.

Goffman introduces the notion of the *team*, which refers to a group of people who are in confluence in order to foster a certain perception of a situation. What is required in teams is a cohesive attempt to manage impression. To do this requires defensive and protective measures or devices such as dramaturgical discipline, dramaturgical loyalty, and dramaturgical circumspection, which are revealed through performers' skillful scripting.

*Dramaturgical loyalty* refers to team members being able to trust each other with secrets and with maintaining boundaries between insiders and outsiders. Implicit is the understanding that performers must "act as if they have accepted certain moral obligations" (Goffman, 1959, p. 212). In other words, a member should not expose secrets or exploit compromising positions to his or her advantage. Dramaturgical loyalty involves acting in a way that demonstrates solidarity among the team members without overcriticizing and underperforming. To exhibit dramaturgical loyalty, a team member must devote him- or herself to the norms, codes of conduct, and group rules.

*Dramaturgical discipline* ensures successful team performances. This requires self-control, not only to uphold a sense of dramaturgical loyalty but also to perform in a way that captures the true image of the team and appears authentic to the audience and other actors. Dramaturgical discipline concerns having the know-how to "cover up on the spur of the moment for inappropriate behavior" that which is not compatible with the social and/or moral codes of conduct of a particular role (Goffman, 1959, p. 218).

A third device used as a defensive measure is *dramaturgical circumspection*. This involves the ability to think ahead to the future and make necessary adjustments or fashion impromptu scripts in the face of uncertain situations where the integrity of a role or representational image of a team is threatened. Unforeseen situations arise that require team members to respond to objections, challenges, and perceived threats to the version of reality a team is trying to negotiate as legitimate.

These theatrical tactics are revealed through scripts that can be written ahead of time (e.g., retail companies). In these cases, scripts can be utilized by management to control employee autonomy. Scripts may or may not be written ahead of time, but nonetheless they are often used

to control the audience's (e.g., customers at a car dealership) view of reality and to persuade the audience to see reality as the actor does.

### *Settings, Props, Costumes*

In addition to scripting, settings, props, and costumes also aid in revealing sincere performances and enacting efficacious protective and defensive measures. Similar to scripting, settings, props, and costumes help facilitate a particular version or social reality. They manage impressions of audiences. Different roles and performances require different, but relevant, settings, props, and costumes.

A costume is usually the quickest way to signal what role someone is playing. For example, the waiter in a restaurant signals that he is on duty when he is wearing the restaurant's uniform. Not all costumes are intended to cue the same symbolic meaning, and some costumes would not be appropriate in certain settings. A person employed by Disneyland wearing her uniform would not look "right" if she were taking orders from a customer at a restaurant.

Location and setting comprise another important factor in understanding dramaturgy. Goffman refers to *situation propriety* as the understanding that the meaning of an interaction depends on the context in which it emerges. Different interactions mean different things in different settings. Team members can manipulate scenery to consciously replace what appears ordinary and mundane with a sense of vibrancy—seeking to alter perceptions of reality.

The concepts of "front stage" and "backstage" are relevant to understanding setting. In scripting a form of dramaturgical loyalty to the restaurant, a waiter does not act or speak in the same manner in the kitchen after dealing with an unreasonable customer as he does when he is dealing with the customer in the dining area of the restaurant. *Backstage* refers to the special dimension of not being seen and/or heard by a given audience, whereas the audience is privy to the performances during front stage performances. By waiting until he gets to the kitchen area where he is free to vent, the waiter is preserving his image as a professional and upholding a reality that the restaurant is customer service oriented.

Finally, performances require use of props—all which can be manipulated to convey a certain meaning and understanding of reality. In enacting a dramaturgical circumspective tactic, a human rights activist might use props such as signs and barriers to defend team members from hostile protests. Costumes, props, and settings set the stage for the dramaturgical imperative "the show must go on."

### Application

Dramaturgy presents an alternative to the examination of organizational practices and their resulting performance. Dramaturgy allows the researcher to explore organizational practices as a performance in and of themselves. For example, consider the common practice in organizations of creating job descriptions for each role in the organization. Instead of focusing on the means and ends, the researcher would examine the process as a performance. The creation of official job descriptions reduces the burden on employees to demonstrate on a regular basis their importance in and to the organization. Instead, this task is given to an individual or group of individuals within the human resources department. These expert players take on the performance of presenting the essential nature of the roles and responsibilities of each employee.

As an example of dramaturgical case research, Peter Manning examined the period of declining crime in New York City during the mayoral reign of Rudolph Giuliani and tenure of New York Police Department (NYPD) commissioner William Bratton (specifically, 1994–1996). The case study looked at the way the police, politicians, and media represented both the causes of the decline in crime and the strategic and tactical actions of the police. Manning examined how dramaturgical concepts could be used to detangle the tenuous connection between changes in the police force and changes in the crime rate and how the media narrative changed over time. Manning also examined the dramaturgical nature of policing and the effort required to interweave the realities and practices of the street-level officers with the often oppositional and incongruent statements and positions offered by the top-down command structure of the force. The spokespeople for the

police force engaged with the media to craft the meaning of policing as a strategic, controllable, and effective tool for the prevention and management of criminal behavior. Initially, the media accepted the police narrative; however, after several controversial events (the most notable being the sexualized abuse and torture of Abner Louima), the nature of the media's coverage changed. Manning suggested that the NYPD lost the ability to manage the spectacle of crime control after this series of events, and the media shifted their focus to the dark side effects of the policing policies they once celebrated.

In contrast to the large scope of Manning's analysis, Catherine Watson presented a microlevel analysis of inmates' representations of self in Tanguay Prison in Québec City. This second example is more representative of the norm in dramaturgical analysis in that it focuses on the co-creation and representation of reality between individual actors and audiences. Watson examined the roles women in the prison were required to play in order to impress the audience of social workers and prison officials toward the purpose of acquiring access to gradual release programs and eventual freedom. Prisoners needed to follow different scripts depending on the nature of their relationship with criminal activity, with the more demanding scripts forced on the women with the more intimate and enduring careers in the criminal arts. Watson also examined the backstage activities of the prisoners in the games of one-upmanship and competition that took place away from the gaze of the prison staff and the effort put into the design of the costume required to convey the correct message of civility and proper moral bearing when in view of the audiences (hair, makeup, etc.).

A third example of case research is Iain Mangham's investigation of a large family-run business. He explored how situations that appear bizarre and contradictory to an uninitiated observer can be elucidated by understanding the purpose of the events in the minds of the actors. In this case, the scene under analysis was the weekly Monday meeting between the managing director (a member of the ruling family) and his senior managers (non-family employees). The managing director had advised Mangham that the purpose of the meetings was to invite discussion and criticisms of proposals and decisions to enhance the firm's

performance. The researcher was baffled by the behaviors of the nonfamily managers in the meeting because these behaviors were contradictory to the stated purpose for the meetings. The managers supplied little discussion and were reluctant to criticize one another or the decisions of family members. Mangham eventually discovered that the managers believed that the purpose of the meetings was a farce (the decisions were made by family members in the family context), and thus they followed the scripts that were in their best interests.

### Critical Summary

The major critiques of dramaturgy attack its descriptive endeavors and its lack of a consistent theoretical framework. To place boundaries and systematize a particular episteme can make it oppressive and exclude alternative epistemic theories. Goffman's dramaturgical perspective, both liked and disliked, is useful for someone desiring to be able to describe and understand rather than prescribe or predict human behavior.

## ECOLOGICAL PERSPECTIVES

---

Ecological perspectives reflect an epistemological stance that places importance on the role of environments. Ecological perspectives borrow concepts from biology as metaphors with which to describe the reciprocity between persons and their environments. Ecological perspectives can be found among a wide variety of academic disciplines. Ecological perspectives are pertinent to case study research since any case study is situated in an environment in which the study's subjects are a part as well.

### Conceptual Overview and Discussion

Ecology originated as a branch science of biology that examined the relationship of an organism to its environment. Beyond this origin, the ecology metaphor has attracted the attention of scholars from many disciplines outside the natural sciences. Influenced by the works of biologists on the interaction of organisms within their environments, social scientists started to engage themselves in examining human groups in a similar way. Ecological perspectives address the importance of environments in the broadest sense.

The present entry focuses on works of the two most influential scholars who contributed to the conceptualizations of "ecology." Urie Bronfenbrenner and James Jerome Gibson made great contributions in psychology and beyond. Bronfenbrenner and Gibson were hardly the first people to point out the

importance of environments in social science. However, both Bronfenbrenner and Gibson are considered to be pioneers in ecological research, placing "ecology" at the center of their academic endeavors. The concepts of "bioecological systems" by Bronfenbrenner and "affordance" by Gibson are discussed below to highlight the major theoretical tenets found in ecological research.

In *The Ecology of Human Development: Experiments by Nature and Design*, Bronfenbrenner proposes a conceptual framework for child development that focuses on the interrelationships between various environmental settings.

Affordances, coined by Gibson, are generally defined as the interactive possibilities of a particular object or environment. His interest in the optic perception of visually impaired people led Gibson to develop the notion of affordances. Gibson challenged the traditional view on vision: namely, the eye serves as a camera to capture an image and the image is transmitted to the brain. To a visually impaired person, this analogy of the eye as a camera would not work. Visually impaired people's ability to navigate is based on detecting environmental structures as revealed over time along a habitually traveled route. These distinct types of information specifying particular route properties are variable and ubiquitous, and are embedded in the surrounding environment. He illustrates the nature of affordances by listing many examples: an apple affords eating; a cliff affords falling off; a sidewalk affords locomotion. Gibson developed the notion of affordances in his more general ecological approach to perception, emphasizing that

affordances are specified by information available in ambient stimulation—the array of light, sound, and other forms of energy surrounding every organism—and thus can potentially be perceived if the organism is sensitive to this information. However, affordances are objective properties of the environment in the sense that they exist whether or not they are perceived. Thus, a situation can be described as a complex set of affordances for an individual, some of which will be perceived by the individual and some of which will not.

### Application

There are a number of case studies where ecological perspectives are applied in a wide variety of disciplines, ranging from psychology, language acquisition and language socialization, development of communication robots, and identity formation to the ecology of language.

Shirley Brice Heath's work is an award-winning in-depth longitudinal study of language socialization in two communities in the rural United States. Heath documented how children learned to use language and how their uses of language established their identity, roles, and relationships among families and friends. Following these children into their schools in the early days of desegregation, she documented how their distinct ways of learning language affected their integration into academic life.

The field of identity studies is also cognizant of the need for alternative models to homogeneous, monoracial, linear models of identity development. Robin Lin Miller expresses this necessity for alternative models among multiracial and multiethnic people. According to Miller, a theory of ethnic identity development for multiethnic or multiracial people should be ecologically anchored, including aspects of boundaries surrounding social groups, principles for accommodating structural change, and rules to describe situational views of self. This factor applies not only to a particular groups' rigidity or fluidity, but also to the rigidity or fluidity of the self-views of multiethnic individuals. For example, a multiethnic person may experience herself as a multiethnic person at home, but within the environment of her Japanese grandmother, she may experience "self" as a descendent of Japan. In such circumstances, social context has the potential to affect how a multiethnic person views his or her own ethnic identity.

In 1970, Einar Haugen proposed the paradigm of "the ecology of language." The ecology of language, later called ecolinguistics, refers to a new ecological study of the interactions between a language and its environment. Ecolinguistics emerged in the 1990s as a new method of linguistic research that took into account not only the social context in which language is embedded, but also the ecological context in which societies are embedded. Pioneered by Einar Haugen, linguistic ecology or ecology of language uses the metaphor of an ecosystem to describe relationships and interaction among the diverse forms of language found in the world, and the groups of people who speak them.

Ecological psychology, pioneered by Gibson, has been extremely influential in the fields of design, arts, ergonomics, and artificial intelligence. Two very interesting applications of ecological psychology in the fields of artificial intelligence and arts are introduced below.

First, ecological psychology was applied to develop and design a communication robot. This robot, called *Muu*, was developed by a group of researchers at Advanced Telecommunications Research Institute International in Kyoto, Japan. *Muu* was designed to simulate human communication in a multiparty conversation as it moves through a human-inhabited environment. In designing and building the sociable robots, researchers embedded *Muus* with an intrinsic "drive" for social interaction. By shifting from an observer's view to an introspective one, we initially experience an "incompleteness" or "indeterminacy" in the meanings and roles of our actions and utterances. These become definite when grounded through social interaction. By moving around, *Muu* detects the presence of a human and approaches him or her and attempts to attract the human's participation in conversation. By engaging in communication with a human, in other words, being grounded through social interaction, the robot's intrinsic drive is fulfilled.

When one talks with others, one responds to their actions and carefully coordinates oneself in getting the conversation going as an interlocutor. As an adult native speaker, one is capable of such complex operations. Gibson calls this operation "perception-action coupling." Miki Goan, as an ecological psychologist, attempts to unveil the mechanism of such complex but commonplace perception-action couplings in

Japanese spoken communication by examining plays written and directed by Oriza Hirata, whose fame lies in his remarkable talent for creating realistic conversation in theater.

### Critical Summary

As a result of Bronfenbrenner's groundbreaking work in human ecology, environments—from the family to economic and political structures—have come to be viewed as part of the life course from childhood through adulthood. The “bioecological” approach to human development broke down barriers among the social sciences, and built bridges between disciplines. Although Gibson himself did not explicate the notion of “affordances” fully, the influence of his work reaches far and wide, as seen in the above example. While the full potential of ecological perspectives in various academic disciplines is yet to be realized, their ongoing development is promising.

Case study research is inherently empirical and situated in physical environments. Thus, elements of ecology are embedded in case study research. Case studies of high caliber not only strengthen the case study as a research method but also promote the theoretical potentialities of ecological perspectives.

## EPISTEMOLOGY

---

Epistemology concerns opinions about knowledge. When do we have valid and reliable knowledge? How do we know that a generalization is factually correct? How do we obtain “the truth, the whole truth, and nothing but the truth” in a courtroom or in a social scientific investigation? Epistemology, therefore, is the philosophical study of the ways in which we can distinguish between knowledge that can be considered by most experts to be scientifically true and information that is not valid and reliable. There is also a philosophical position that extends epistemology to the notion of sound common sense.

### Conceptual Overview and Discussion

Many people in everyday practical situations believe that they can recognize the truth “when they see it” and do not bother with the nuances of deeper epistemological issues. However, utilization of everyday-life common sense can lead to significant errors, as in eyewitness testimony or the interpretation of hoaxes or spam and bogus Web sites online. Epistemological considerations need to be taken into account for sophisticated understanding of any research results, but they are often overlooked, as in the use of results from public opinion polls or from case studies of various kinds. For example, what is the epistemological status of case study material from a psychoanalytic therapy situation? Many researchers ignore epistemology when establishing their research design, but that makes them like the drunk searching for his keys under the street lamp though he probably dropped them in the dark. A quantitative analysis that uses variables at the categorical, nominal level of analysis often cannot be interpreted to reveal the results that some researchers would like to extract from

the data. Although many factors enter into research design, one's epistemological convictions often help to determine the types of methods and techniques that will be favored. Charles Ragin has written on this question and has indicated through rigorous analysis the ways in which many researchers make mistaken assumptions about the validity of results obtained through cross-tabulation. Though not always the case in the social sciences, those who favor a positivist epistemology are more likely to utilize quantitative methods, while those who lean to more interpretive approaches often emphasize qualitative methods. Although not universally applicable, particularly when several cases are being compared, most case study research—particularly studies of single cases—tend to be interpretive and qualitative. The emphasis on interpretation of human meaning in one or a few cases rather than broad statistical patterns in a large number of cases (or a sample of the population) is an epistemological decision. Efforts to combine quantitative and qualitative research techniques often do not face epistemological issues squarely. Many quantitative researchers may discuss a few of the cases discovered during survey research or other positivist approaches, but the discussion of such cases is often, ironically, not very systematic or thorough. Case study research takes time and effort. It cannot simply be an “add on” to essentially quantitative variable analysis.

### *Historical Perspective*

Many students and even many researchers have great difficulty with the term *epistemology*. To many academics it appears inexplicable. Lack of clarity is due in part to a failure to grasp the historical development of the term. To fully grasp the idea behind epistemology it is useful to have a historical perspective. A succinct general overview has been put together by Randall Collins, a well-known sociological theorist who has examined worldviews, theologies, and philosophies historically and comparatively. His comprehensive treatment allows us to situate the Western European rise of universities and disciplines. It is only with the rise of specialized academic disciplines at modern universities, starting particularly in German-speaking Europe in the 19th century, that epistemological concerns could be radically

separated from metaphysical concerns related to theology and premodern philosophy. Philosophical inquiry became a specialized academic discipline only after thinkers like Immanuel Kant and G. W. F. Hegel separated the study of phenomena from theological and metaphysical concerns.

The history of methods and techniques in the social sciences cannot be separated from broader philosophical concerns. Epistemological innovations led to significant changes in theoretical and methodological approaches, which eventually led to innovations in more specific methods and techniques. It is not possible to have interdisciplinary research involving interpretive case studies without beginning with a solid foundation in two or more disciplines. When two disciplines have radically different epistemologies it is not possible to move beyond mere multidisciplinary; but, when two disciplines share some epistemological similarities, then true interdisciplinarity can become a more viable goal. An interpretive sociologist and an interpretive psychologist can find some degree of common ground on the basis of a shared emphasis on interpretation of human meaning, just as a positivistic sociologist and a positivistic psychologist may find some overlap in statistical techniques such as factor analysis. Some of the cutting-edge or emerging and “emergent” work in the social sciences in the 21st century involves interdisciplinarity. But it is often not so much a matter of “thinking outside of the box” as thinking within two very similar epistemological boxes. To the extent to which 21st-century interpretive case study research can be considered “scientific” (at least in the broader sense), it must be firmly grounded in well-developed, highly sophisticated understanding of epistemological issues within disciplines.

### *Humanistic Scholarship Versus Modern Science*

Epistemological distinctions between science and other forms of research are accepted by many academics. It is regarded as axiomatic by most university researchers that even the best scholarship is not clearly and unambiguously scientific. In English, the word *science* has come to mean a kind of activity that is clearly not “scholarship” in the strict sense. For example, if a scholar translates a Sanskrit text into French, that is scholarship but it

is not regarded as science. In German the word for science is *Wissenschaft*; the German word tends to allow for a much wider range of academic activities. Few academic researchers interested in interpretive case study research would deny that it is possible to make a fairly clear-cut distinction between humanistic scholarship and modern science. (Well-known 19th-century German scholars like Wilhelm Wundt and Heinrich Rickert debated the nuances of this problem and arrived at ingenious answers.) Since the 17th century, a “scientific” approach has gradually become differentiated from a “humanistic” approach. While it is somewhat anachronistic to use the terms in that way, especially since early modern science was regarded as “natural philosophy” and one of the “liberal” disciplines, nevertheless science and scholarship have gone their separate ways. In the late 20th century many critics pointed to the fallacies buried in the optimism of research conducted a few decades earlier. In the 1950s and 1960s the topic of epistemology was often ignored altogether. Feminist scholars, many of whom come from a humanist tradition, have been particularly critical of simplistic assumptions about the impact of implicit assumptions concerning gender roles. For example, if it is assumed that women cannot attend college, as was the case for many female novelists, particularly prior to World War II, then it will inevitably be the result that women’s contributions to all disciplines will be viewed as less significant. A famous example is the neglect of women scientists who worked in genetics and astronomy, but we forget quite easily today how difficult it was for many women, even in the humanities and social sciences, to receive full recognition for pathbreaking contributions.

### *Hermeneutic Rules*

If we consider the possibility that there is no clear black or white epistemological gap between science and nonscience, then we can move to a conceptualization of epistemological approaches along a continuum from extreme, lawful (“nomothetic”) positivism to radically descriptive (“idiographic”) humanism. Many aspects of social science can be considered to fall somewhere along that continuum, and not just in one limited way. That is, while some social science may be nomothetic and while other

aspects may be idiographic, there is a great deal of social scientific research that is neither one nor the other. Some argue that the terms nomothetic and idiographic actually represent “pure types” at the extreme ends of a continuum and that most social science research falls somewhere between the extremes, midway along the continuum. In other words, we can extend the notion of “interpretation” to cover much more than used to be meant by “interpretive social science” during most of the 20th century. With what Richard Rorty has coined the “linguistic turn” (or “narrative turn”) of the late 20th century, there was a rediscovery of hermeneutics and semiotics. How do we read a “narrative”? How do we make sense of words on the printed page? While even today many people associate hermeneutics strictly with theology, the idea of systematic interpretation has been extended by writers like Paul Ricoeur. Some thinkers, particularly those who follow the Science and Technology Studies (S&TS) approach, argue that there is no clear cutoff point among interpretive practices and that even the “hard sciences” do a great deal more interpretive work when analyzing data than refereed journal articles would make one suppose. Nevertheless, it is clear that the so-called soft sciences require a great deal of interpretation of human meaning. That is what prompts many social scientists to use detailed information from a single case (or a relatively small number of cases) and eschew more superficial information from large numbers of cases studied in a somewhat perfunctory manner. The epistemological consideration is similar to the popular aphorism: garbage in, garbage out (GIGO). Yet, many researchers remain relatively “modernist” in their axiomatic assumptions about epistemological validity.

### *Postmodernist Epistemology*

Some authors, like Norman Denzin, have referred to a crisis of representation and legitimation in social science. Postmodern social theorists argue against positivist epistemological assumptions, which makes sense to most interpretive social scientists, but they continue that line of argument to what they regard as its logical conclusion. They argue against *any* form of unthinking essentialism or narrow foundationalism. Many positivists regard such arguments as exaggerated

claims, or even outright charlatanism. Yet, many interpretive social scientists recognize at least a grain of heuristic value in some aspects of postmodernist antifoundationalism. It is widely acknowledged among qualitative researchers, for example, that generalizations have to be made on the basis of deep knowledge of situational context, both in time and in space. Nevertheless, to the extent to which authors like Michel Foucault or Jacques Derrida make arguments favoring one viewpoint rather than another, they have to have at least an implicit epistemology. The postmodernist or neomodernist position cannot end with negation. It must continue with the dialectic in order to reach an epistemological position that allows for research, including case study research. That position has to go beyond being simply a critique of premodern and modern standpoints. There has to be something “positive” in even the most negative critique if the author is going to put forward assertions about pattern and processes.

Derrida’s postmodernist epistemology centers on his conceptualization of what he calls *differance*. He invents this new word to distinguish two meanings concealed in the French word *différence*: (1) a distinguishable aspect of some phenomenon and (2) the diachronic context of different meanings at different times and the “deferred” use of words and other signs. An example might be the use of the signifier “gay.” When we sing “Don we now our gay apparel” we utilize the sign differently than when we discuss homosexuality. We are able to differentiate in both senses of *differance*. Contextualization of meaning in the use of words and other signs provides a higher level of “objectivity” than ahistorical and atemporal/acultural speech or writing. Hence, every statement regarded as factual can be a “fact” only in terms of some standard for evaluation. Derrida is regarded by thinkers like Thomas Baldwin as “deconstructing” the *differance* between many utterances. That is especially the case when it comes to implied dualisms. Every discourse about “objectivity” assumes its antonym, “subjectivity.” When we move beyond the Cartesian subject–object dualism of the past 400 years we then also move away from “modernist” epistemology. Modernists take the concept of objectivity for granted, but the very term *objectivity* has to be differentiated from its opposite and contextualized historically and culturally. In other

words, Derrida makes sense if we read him with an appreciation for his radical critique of assumptions that originated in the 17th century, at the beginning of the “modern” era in European and, eventually, world history.

### *Feminist Epistemology*

Just as many thinkers reject postmodernist radical epistemological “deconstruction,” there is often antipathy to feminist writers who claim that the viewpoint shared by women is distinctive from the masculine (or “masculinist” and “patriarchal”) perspective. Many feminists have criticized science and the humanities, as well as the social sciences, for a lack of attention to the feminine standpoint. Women see things differently, it is argued, because they are located in a different “space” and therefore see social reality differently. Sociological theorists like Dorothy Smith have called this feminist standpoint theory. Smith advocates starting from where women are, which for the most part is at a lower rung on the stratification ladder. It can be argued that the very idea of a separate and superior feminist epistemology is logically contradictory. Cassandra Pinnick, for example, argues that feminist epistemologies that radically challenge non-feminist epistemologies cannot resolve the conflict between a theory’s stated aim and the goal of showing how it is better than rival views. That is, there is an internal contradiction. To claim that all epistemologies are relative and contextual makes it difficult to argue as well that a feminist epistemology is superior. If any particular feminist epistemology is superior, then it cannot be the case that all epistemologies are merely social constructions. If *all* epistemologies are merely artifacts, then feminist epistemologies would have to be mere contrivances as well. A similar circularity is often said to exist within various forms of critical theory and postmodern theory. At the same time, a strong defense of decidedly feminist epistemologies is that they have addressed issues related to epistemologies developed within a framework of patriarchal domination. The question then becomes how anyone can escape patriarchy defined as all encompassing and determinative. Nevertheless, it may be that if we carefully differentiate various types or stages of male domination historically and contextually, we can also distinguish among kinds of epistemological

conviction. After all, most social scientists who are “modernists” believe that modern science is epistemologically superior to premodern ways of thinking. Even in the humanities there tends to be a view of modern science that allows for science as epistemologically different from humanistic scholarship. In the 21st century, women’s voices are being heard more frequently and there has been heated debate concerning nuances of the sex divide when it comes to epistemologically well-founded truths. For example, there is continuous debate concerning the social scientific merit of separate women’s studies programs. Does sex/gender make a difference in how human beings interpret data? Is there a separate and distinctive woman’s way of knowing? The same basic epistemological problem also extends to nationality and citizenship, race and ethnicity, class and status, and many other social structural considerations. Can someone exercise empathetic understanding if she or he is not a full member of the community or group? How “scientific” is interpretive case study research done by someone who is an outsider, even if he or she is a participant observer?

### Critical Summary

The topic is complex and cannot be summarized in a thousand words, hence the further readings below are important. Even the use of key words like *gender* or *modernity* can be subjected to epistemological concerns. Do feminists who use the word *gender* mean an ordinal level variable or are they mainly concerned with differences between biological women and biological men, regardless of sexual preferences and behaviors? Do postmodernists hold a completely consistent position or are there many different kinds of internally inconsistent Postmodernist epistemologies?

## EQUIFINALITY

---

*Equifinality* is the concept of multiple paths to a common end state. It is an important element of general systems theory, as conceived by Ludwig von Bertalanffy in his effort to unify the sciences, and interpreted by Daniel Katz and Robert Kahn for organizational studies. Equifinality is an implicit assumption of case study research that presupposes that each organization is unique and that local details such as employee expertise, technology, and economic and cultural environments matter in the determination of organizational outcomes.

### Conceptual Overview and Discussion

Systems theory assesses physical, organic, and social processes with regard to resources or inputs,

transformations, results or outputs, and recycling of resources. A closed system provides a singular and determinate path to a specific result. It implies a fixed chain of events. On the other hand, open systems interact with changing environments. By virtue of environmental uncertainty, open systems are more difficult to predict but may generate parallel outcomes from multiple trajectories, as reflected in the concept of equifinality.

There are many physical, natural, social, and personal processes that exhibit equifinality. For example, similar geological formations may arise in multiple ways. Distinct species may exhibit parallel adaptations or similar characteristics as a result of natural selection. Individuals may contract a disease or experience a psychological condition (e.g., borderline personality disorder) from different sources and contexts. Organizations may generate high-quality production through multiple paths.

Equifinality demonstrates the logical error of affirming the consequent. While Event A may produce Result B, one cannot assume that Event B would bring Result A. However, the absence of Event B should guarantee the absence of Event A. When there are multiple paths to a common result, one cannot be certain which path has been followed.

Equifinality figures prominently in Katz and Kahn's work on organizations because it facilitates diagnosis of organizational problems, and does so better than any deterministic and unidimensional analysis. Katz and Kahn deliberately situate organizational studies in the spectrum of sciences subsumed by systems theory.

### Application

Organizational studies researchers have found multiple organizational configurations that lead to similar results in profitability, employee turnover, and product quality. For example, Robert Paul MacDuffie and others have described a binary path to quality in auto manufacturing. At one extreme, Volvo once produced high-quality automobiles through a system of autonomous working groups. On the other hand, Toyota developed a lean (and less expensive) manufacturing model with far less employee discretion but similar quality outcomes. The concept of equifinality within open systems theory anticipates this discovery of convergent results.

### Critical Summary

Equifinality enhances the value of case studies. Causal connections cannot be casually inferred in organizational contexts. Social systems do not conform to mechanistic models of class struggle, technological change, or scientific advance. Case studies reveal the details of institutional development and illustrate the complex paths of organizational change, the multiple contingencies and outcomes.

## ETHICS

---

*Research ethics* refers to moral standards for research practices that involve humans. It is culturally expected that researchers “do the right thing” for fellow human beings in all their social research. But it is no longer left solely up to individual researchers to behave in the best interests of research participants or the profession. In most countries and fields, research is governed by institutionalized, documented codes, overseen by authoritative agencies or “ethics review committees” (e.g., American “institutional review boards,” IRBs; Canadian “research ethics boards,” REBs).

This entry is organized in three parts. Part 1 sketches typical emphases of the codes, summarizes

key rules of ethical research conduct, and forewarns of challenges in implementation. Part 2 highlights problems in organizational mechanisms managing the codes, and advises practitioners accordingly. Part 3 summarizes philosophical, cultural, and political contexts of the current normative landscape in research.

Much of this article rests on the well-developed, interdisciplinary ethics policy governing the core research community in Canada, maintained by the Interagency Panel on Research Ethics, and expressed in the *Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans*.

## Part One: Ethical Principles and Codes

### Basic Guidelines

#### Foundation

As the central imperative of conduct toward participants, the *Tri-Council* code asserts the primary value of human dignity in the holistic sense of guarding the physical, mental, and cultural well-being of the individual.

#### Basics

Basic rules of conduct are variously grouped and labeled, but cover these seven issues: (1) Do not harm participants. (2) Maintain their privacy. (3) Bring them available benefit. (4) Inform them about the research. (5) Involve them only voluntarily. (6) Ensure research of good quality. (7) Be honest with data and reporting.

In the strictest jurisdictions, ethics committees require a thorough summary of key components of the design, and written rationales for all elements with ethical implications, such as: purpose of the study, scientific and applied value, sampling design, modes of getting data, lists of survey questions, experimental or quasi-experimental procedures, information given to participants, mode of securing consent, provisions for protecting identities, and probabilities of harms and benefits to participants (and researchers' steps to minimize the former and maximize the latter).

#### Four Complications

Ethical practice is not as simple as the list implies. First, ambiguities, dilemmas, and contradictions emerge in the implementation, and "rules

for breaking rules" are unavoidably incomplete. Second, rules apply in some circumstances but not others, or in varying degrees. Third, pressures frequently build to take shortcuts. Fourth, the approval process before an ethics committee is sometimes a challenge in itself. For all these reasons, every social-behavioral researcher needs training in ethical matters, or good self-education.

### *In Whose Interests?*

Cross-pressures impinge on researchers' judgments. Which interests are to be served? In what priority? This concern takes at least three forms: (1) advancing science versus protecting personal well-being, (2) managing combinations of stakeholders, and (3) serving the profession. However, the bottom line *prioritizes the well-being of participants* in the event of conflict with other goals or circumstances.

#### Science Versus Persons

Motivated by commitment to truthful knowledge and desire for technical advancement, the prevalent epistemology associated with modernism assumes that improved scientific knowledge fosters progress. This impetus, however, can conflict with the wishes or well-being of persons from or about whom empirical information must be obtained. Science is ethically restricted, sometimes drastically, by cultural imperatives around legitimate actions toward persons. As a blunt example, prevailing norms prohibit imagining that individuals, in the name of science, be treated experimentally to social abuse and then entrusted with young children's welfare, yet such a design could crucially test whether and how victims of abuse pass it along.

To reiterate, persons trump science in today's consensus. Nonetheless, some forms and degrees of risk are permitted in treatment of participants. "Rules for rule-breaking" are indicated, where relevant, in the following discussions.

#### Other Conflicting Stakes

A study involves various stakeholders, with varying motivational mixes and power: project participants ("human subjects"), constituencies that participants represent, researchers themselves, employing institutions, funding agencies, contractual clients, politicians, and so on. For example,

*researchers* themselves may be concerned with balancing advancement of knowledge, delivering practical benefits to humanity or sponsors, promoting their careers, dealing with members of the team, and staying within budget. A *client organization*, commissioning a study, may constrain the project toward reaching conclusions that favor organizational vested interests. Actual *participants* may want to contribute, while “gatekeepers” for their community might object.

To manage wisely the ethical imperatives, researchers must *know* this social context and how cross-pressures can generate ethical issues (hence, practical challenges) for their work. It is smart to map these features of the case study, to consult stakeholders in advance, and to seek advice of knowledgeable colleagues.

#### Professional Stakes

Science depends on *trust*. Two concerns ensue: reliability of the scientific knowledge base; and the public good name of research.

First, despite checks and balances in scientific culture (rigorous training, replication, peer review, and critique), one can readily misrepresent methods or findings. Obviously unethical, under cultural proscriptions about lying and the assumption that distortions *set back our knowledge base*, dishonesty harms us all.

Second, exposure of a lying researcher undermines *public trust* in science and scholarship generally. This sets back future research by reducing the likelihood of funding or the credibility of well-researched policy recommendations. More deeply, it diminishes popular trust in the social system, hence community cohesion.

#### Rights of Individuals and of Groups

The liberal ideological tradition, predominant in ethics codes, emphasizes rights and well-being of *individuals*. However, in practice, rights of *collectivities* (differentiated communities) are also crucial. For instance, ethical assessment of research proposals commonly takes into account interests of those minority communities that have mobilized politically to assert their rights.

Regardless of direct pressure to avoid studying a community—or to suppress results—many researchers confront issues of whether and how to report

findings that could significantly disadvantage that community. Nate Johnson, for example, once wrote a perceptive piece on the issue of sociologists destructively “brangin’ heat” upon a ghetto.

#### Research Quality as Ethical Concern

The scientific quality of a research project has ethical implications that are sometimes included in codes. Two reasons are cited. First, it is inappropriate to have persons invest effort—and sometimes hope—in studies that are likely to produce untrustworthy results. Second (like exposed research lies), poor research damages future cooperation with legitimate studies, just as the annoyance factor in telephone marketing has damaged scientifically motivated surveying.

#### Minimizing Harm

Following from the principles of “human dignity” and “welfare and integrity,” the most obvious rule is the Hippocratic oath: “First, do no harm” or *avoid harming people* through research. What constitutes “harm” takes infinite forms and becomes murky, as the preceding discussion indicates. Like most ethical norms in research, it requires serious analysis, considerable life-wisdom, and negotiation with gatekeepers (including ethics committees). It is important to realize that harm extends to psychological threats to participants’ emotional balance and selfhood, as well as to social damage through exposure of discrediting information, and to research interventions that could rebound negatively upon the cultural system of the group(s).

#### Criterion of Minimal Risk

The central codes of both the United States and Canada feature a standard of *minimal* risk. This does *not* designate the injunction to minimize harm (itself a requirement), but rather, a guide to *degree of scrutiny* to which an ethics board should subject proposals. Both these codes set the participant’s *risks in everyday living* as the threshold at or below which research participation remains minimally risky. If joining the research would increase the likelihood or intensity of harm to the person beyond that level, then the ethics reviewers must look for offsetting safeguards in the research

design, or impose them, proportionate to the potential harm. The Canadian definition further requires reviewers to imagine how the participants *themselves* would reasonably perceive and judge the risks of taking part in the study, relative to their daily circumstances.

#### Criterion of Proportionality

The notion of *proportionality* is treated in two senses. One is the tradeoff between foreseen harms and benefits of a study. The second, invoked here, is the guideline that the degree of independent oversight (including initial approval by review mechanisms) be proportionate to the perceived potential for harm to human participants. Thus, perhaps, a proposal implying “minimal risk” may receive “expedited review” (a less probing check by, for example, one or two committee members).

#### Conditions Permitting Risk of Harm; Balancing Harms and Benefits

If we set the standard as prevention of all types of potential harm to all participants, research could not proceed. (Imagine a highway accident for a participant en route to an interview.) Thus, an implicit calculation of probabilities of degrees of various risks comes into play, placing a significant yet inescapable burden of sincerity and intelligence upon deliberations of both researchers and ethics committees.

When a project exceeds “minimal risk,” how are limits set on exposure to risk? Besides “informed consent” (the first precondition) and the criteria of scientific worthiness and lack of viable alternative approaches, researchers must convince the ethics committee that greater risk is hedged by the following conditions: (a) researchers ensure that all other standards of ethical conduct are met; (b) benefits to participants would reasonably outweigh risks, or, barring this, that benefits to larger categories of people would be truly valuable; and (c) all possible steps are taken to protect participants. However, the more severe the degree and types of perceived risk, the greater the likelihood that adjudicators will reject the project, regardless of benefit, on grounds that participants’ rights ultimately take precedence, and that there are prevailing cultural–historical reasons to restrict tightly the treatment of humans as fodder for science.

#### Protection of Privacy

Although billed as a distinct principle of ethics, respect for *privacy* is normally a practical issue in *preventing harm* to persons. When someone discloses opinions, actions, or circumstances, such information is to be withheld from others whom the participant has not explicitly authorized to know it.

Boundaries of privacy occupy two levels. Data are *anonymous* (nameless) when nobody but participants know who disclosed particular information (common in surveys). By contrast, when researchers can link data to providers, but vow to conceal identities, data are *confidential* (keeping faith with, trust). It is important to use the terms appropriately, and to ensure which form of privacy is pledged to participants.

#### Informed Consent and Voluntary Participation

Among ethical injunctions, *informed consent* and *voluntary participation* are perhaps most directly under the control of researchers. Simply: (a) ensure that participants clearly understand what they are getting into; and (b) prevent any coercion from influencing their consent.

How to do this, under real-world circumstances, can be more complex. Imagine the preconditions for ensuring that all participants *adequately understand* the information about the study, their involvement, and likely risks and benefits. Also, special provisions are needed for participants ill equipped to appreciate the information or to indicate free consent (very young or cognitively impaired persons, groups subject to coercion, or people desperate to gain favor). *Written* (signed) consent is considered best; where that is unfeasible, *oral* consent is permitted, with precautions.

To complicate practice further, special rules do permit studies where distorted information is given to participants in advance or their consent is not obtained. *Deception* of participants (lying to them, especially about study purposes) is permitted under strict preconditions: (a) that the study would provide important knowledge; (b) that misinforming participants is necessary to research purposes; (c) that probability of harm to participants is trivial; (d) that participants will be “debriefed” (truthfully informed and psychosocially supported) after

the fact. By extension, similar provisions govern *covert* research in which participants are unaware that they are objects of study (although *anonymous public* settings are exempted from such concerns). Ethics committees are especially vigilant about these matters.

### *Analyzing and Communicating*

In processing data, interpreting empirically, and reporting methods, the ethical obligation is to be sincere and forthright about the full negative-and-positive spectrum of factors affecting the trustworthiness of the research conclusions: in short, to be honest.

A special pair of issues pertains to participants. First, how much information, and what type, are they entitled to at the end of the project? Codes often suggest that findings be returned to them (even in situations other than applied research under contract), at least in ways beneficial to the community, while guaranteeing protection against individual harm. For instance, it is common (where relevant) to include a provision like this in the informed consent: “If you would like to have a summary of the results, [here is what to do].” The second question is: How do we protect identities of individuals we portray in our case studies? In qualitative reports, particularly, we commonly hold up an exemplary individual, with verbatim quotations, accompanied by indicators of the speaker’s position along social dimensions that typically would influence a person’s views or actions. Such information helps others from the population to pinpoint the speaker’s identity. Some researchers advocate revising the traits—such as age, gender, job—in ways that would not distort the findings meaningfully.

### *Bringing Benefit*

The principle of *beneficence* (doing good) advocates striving to maximize project benefits to human beings. Researchers are enjoined to improve the lot of participants to the extent of the project’s reasonable capacity. More commonly, the rule is satisfied indirectly by the yield for “society at large” and the need for quality work. Because the standard of beneficence is more elusive than that of minimizing damage to participants, it does tend

to be overshadowed by concrete and immediate concerns about harm.

### *Inclusiveness*

Another important principle is *inclusiveness*. This is intended to deter two counterproductive tendencies of past researchers. One was to choose participants of a specific type and then to extrapolate to “people” in general (notoriously in terms of age, gender, and class). The other was to focus on improving the lot of their type of participants while recurrently neglecting the needs of other categories of people (such as the elderly, ethnic minorities, females, persons of other cultural traditions). It is essential, then, to explain and justify the grounds upon which the project will focus upon a specifically bounded population.

A rather discrepant challenge arises when the project involves researchers from one politically and culturally hegemonic population, with participants from a subordinated population. Two obligations come into play: to demonstrate that the project has the approval of participants; and to show why it is significant to the research question to target this particular population as a data source.

### *Conflict of Interest*

*Conflict of interest* exists when a researcher has a personal stake in the group under investigation and the empirical outcomes could significantly affect that group’s interests. Researchers should deal explicitly with such concerns, both in the ethics application and in the field work journal (as issues arise). The questions are especially germane in *participatory action research*, where community members join the team to study and improve their own circumstances.

### *Ethics and Laws*

Closely linked to *ethical* considerations are *legal* concerns, “criminal” and “civil.” The team must be especially diligent in tackling potential problems (and seeking legal advice) at the earliest stage.

Research ethics and legal codes occasionally come to loggerheads, with a researcher as quarry for the two competing hunters. Researchers can be jeopardized in trying to obey legal and ethical requirements simultaneously, and may be forced to choose a haven when the directives are mutually

contradictory. Likewise, a researcher who becomes privy to information about criminal acts will face the challenge of violating confidentiality. These matters are far too complex and contingent to warrant quick descriptions or advisories here, apart from a condensed forewarning. Major extant codes do provide helpful advice, but each case faces its own unknowns.

Sometimes research design and field work routines can place researchers themselves in criminal legal jeopardy (e.g., participant observation in a biker gang). (To clarify: placing *participants* in legal jeopardy is a different matter, and falls under “avoiding harm.”) Also, the mandates of professional ethics and of the state judiciary sometimes come into conflict, presenting the researcher with a major dilemma: for example, when a subpoenaed researcher must choose between violating participant confidentiality and incarceration for contempt of court. Legislation and legal precedents remain ambiguous and variable on these matters. The only appropriate comment here is to foresee such events as well as possible in a given study, to consider all factors (including the sequence of priorities of interests of all stakeholders), and to act so as to maximize human well-being (even if far more easily said than done).

#### *Variations by Research Design*

The special issues entailed in different designs are too many even to summarize here. Within a case study, quantitative and qualitative modes of generating data invite quite different considerations. Quasi-experimental, sample survey, focus group, and participant observation techniques likewise bring out varying challenges. The best advice (besides knowing well both the core ethics material and the particular research setting) is obviously to search out treatises on, and exemplars of, ethical practices in the genre or in similar field work sites. In addition, as explicated below, practitioners who transcend the stereotypical quantitative methods are particularly cautioned to scope out the approval bodies they might encounter, in which familiarity with their methods can often be extremely scarce.

#### *Exemption From Review*

In some jurisdictions, certain designs are exempt from committee examination. Given their low ethical threat, the following may be permissible on

the face of it: anonymous surveys; secondary analysis of anonymous data; observations in anonymous public places; interpreting verified information preexisting in the public sphere; suspending confidentiality for data about individuals occupying prominent public positions; testing of, or data collection about, students or organizational members, either for ordinary pedagogical purposes or for routine processes of managing the organization. Such a listing cannot be definitive. It varies formally by jurisdiction (e.g., according to research methods guru Earl Babbie, the federal requirements in the United States could effectively exempt much of social science research, while in Canada, exemption is quite rare), and informally by negotiation and by traditions of normative interpretation. In addition, certain preconditions may be attached, such as an advisory that survey instruments should include ethical pledges to respondents. Also, committees do commonly require application for *every* project about humans, so that they might be triaged for exemption, simplified checks, or full committee debate.

### **Part Two: Bureaucracy and Beyond— What to Do**

#### *Problems With Ethics Committees*

Apart from contingencies of uneven expertise, individual temperaments, and the politics ever-present in group decision making, problems arise in ethics adjudication committees when members fail to appreciate the *disciplinary* or *methodological* traditions of the colleagues proposing a given project. This situation has supplied much fuel for scholarly critiques of the current institutional apparatus around research ethics. Objections have been especially vociferous from social researchers against committees dominated by medical clinicians and “natural” science practitioners, especially those schooled within the boundaries of experimental design, who may have little grasp of the perspectives of social-behavioral (and humanities) disciplines. Applicants’ level of frustration has been magnified by the fact that many of the prevailing ethics codes originated from medical circles, and tend to maintain that focus, to the detriment of diverging research questions, designs, and practices appropriate to other realms of inquiry. And among social-behavioral researchers, those advo-

cating *qualitative* procedures have been especially stymied by committees that fail to grasp the emergent contingencies and the unanticipated circumstances required in the very design of many qualitative research plans.

Stories recurrently circulate among researchers about cases where overly rigid or misplaced ethics scrutiny has snuffed out potentially important studies. Numerous researchers have testified to switching their programs away from topics likely to get a rough time from committees. Ethics applicants should investigate carefully in advance what they are up against in their particular milieu of approval mechanisms, and to strategize accordingly.

### *Practical Preparations for Ethics Review*

#### Reading Up

In many disciplines of social science, the leading textbooks for introductory courses in research method will contain helpful chapters on research ethics. Clearly, especially useful sources are those tailored to the research genre of one's project, and those written in the national context(s) of the project's setting. Likewise, it is imperative to study the official ethics guidelines of the specific jurisdictions and professional associations within which the project falls.

#### An Ethics Inventory and Account

As a commonsense measure, it is very helpful to prepare an "ethics outline" or matrix, including all anticipated issues and how the study proposes to manage them. This not only reduces nasty surprises during the ethical approval process or during field work, but is also useful in drafting the ethics proposal itself.

Similarly, the project journal file (itself a crucial general resource, not always receiving due attention)—kept throughout the research sequence—should include notes on every matter touching upon matters ethical and legal.

#### Knowing Whose Approval Is Needed and What to Do

Every research team must carefully check the ethical rubrics applicable to its circumstances. A great many national states and international political jurisdictions have ethical codes for health or medical studies, but lack centralized codes for

social research as such, whether academic or applied. However, particular disciplines and organizations commonly do have them. In addition, for self-protective if not also moral reasons, any researcher is strongly advised to ensure that treatment of human participants, individual and collective, is reasonably acceptable to those participants and to those who might intervene on their behalf, regardless of the letter of the officially sanctioned provisions. It is not only institutional committees that might object powerfully to measures that researchers undertake. In the field work site itself, significant objections may emerge, and foreseeing them can make a crucial difference both to the project's final report to its ethics committee(s) and to the practical level of community cooperation around access to needed data.

At the stage of obtaining official ethics approval for the project from committees, it is essential not only to study pertinent guidelines and address the formal requirements, but also to ensure that one appreciates the unstated assumptions of the code and of its enforcers, and how to address those concerns accordingly. In a word, save trouble by asking someone in the know.

Note that a particular project—especially one done by a team—may come under the purview of two or more official jurisdictions of ethical oversight. There may be specialized committees for disciplines, levels of governance (national, local), particular organizations (universities, hospitals, etc.), multiple research sites, and special populations. Each ethics committee has its own rules, its own mix of members, and its own politics. Also, a project may cross political borders. A research team may be based in one or several places, while data and participants are found in one or more other jurisdictions. Especially when a project spans national frontiers, its directors must determine which formal codes pertain and how to satisfy the potentially multiple arrays of ethical stipulations. In the case of anticipated contrasts in cultural background assumptions of the populace or of gatekeepers, the most far-seeing project overseers will also do the necessary homework around informal expectations of acceptable conduct.

#### Budget and Timeline

When estimating the timeline for the project, it is essential to allow for the ethics approval process,

which is commonly overlooked during the application for funding. Thus it can be most helpful to investigate first the typical pace of decision making within the relevant approval processes.

For the rare case study with both an ample monetary budget and a controversial design, it can be worthwhile to bring in an expert ethicist.

#### Revising Plans

Sometimes researchers discover they must revise their design or methods after the project is under way. Typically, one is obligated to approach the ethics review committee for approval of any change that could significantly affect the potential ethical contingencies of the project. Many committees provide relatively speedy consideration of such changes.

#### Summary Advice

Researchers can never guarantee that participants' engagement in the project will not impact negatively on their well-being. With the best intentions and planning, some things will most likely go wrong, especially in field work. The only countermeasures are to be ever vigilant and to maintain open communication with all relevant parties.

### Part Three: Wider Perspectives

Researchers on a tight schedule can relegate this last section to moments of leisure. Here the agenda very briefly addresses philosophical grounds of research ethics, alongside social, cultural, political, and historical perspectives on where we are today in these matters.

#### *Grounding of Ethical Principles*

This entry would frustrate most ethical philosophers to distraction, since it deliberately foregoes significant discussion of the complex understandings and multiple contrasting conclusions that scholars have achieved over the centuries. Those debates are far from irrelevant to social researchers, but this entry must hand the work over to other reference sources. This entry notes only two of the many nuanced answers to this single question: *On what basis are the rules of ethical research founded?*

Two very general and contrasting types of answers to this question are: *rational-foundationalist* and *social-constructionist*.

#### Constructionist

Either inherent "natural" rules are the mythical product of ideology or they are secondary to what actually happens, so what needs to be taken into account are the *historically and socially constructed norms prevalent in the cultural order* within which rules of research behavior are being established and implemented. This is the prevalent working viewpoint in social science, and the operational assumption of this entry.

#### Foundationalist

By analyzing intellectually the very *nature of things*, and especially the nature of humans and their shared living, we can eventually deduce the inherent principles of human rights and of proper conduct toward one another, and from there we can devise correct rules of research behavior. This viewpoint persists in philosophical and popular debates, and remains the stance of some scientists who consider the issues at this level.

#### *Cultural and Political Context of Contemporary Concerns*

To grasp the current norms around research, one needs a sense of the sustained humanistic and political reaction against egregious transgressions of human rights in the second half of the 20th century and the history of famously controversial cases. Details are beyond the bounds of this entry. It is sufficient to cite some of the best-known examples. The Nuremberg trials of Nazi Germans exposed human atrocities, including medical and other scientific experiments that were intensely politicized by the victorious prosecutors and provided the fountainhead of latter-day debates around research ethics. Enduring human rights and colonial independence movements in the subsequent decades, and attendant attention to other troublesome studies, brought to a crest the pressure for ethical codification and bureaucratic regulation. Among the other provocative studies, some of the best-publicized North American examples are Stanley Milgram's electroshock obedience study, testing proclivity to inflict harm upon others solely through commands to do so; the Camelot Project, involving academics in counterinsurgency research in Southeast Asia during the United States' embroilment in Vietnam; the Tuskegee syphilis study, in which black males of the

deep southern United States were denied available medical treatment in order for researchers to observe physical outcomes of the disease; and the CIA and McGill University studies of brainwashing techniques in Montreal, Canada.

A more general and amorphous challenge bears mentioning since it could impact upon a researcher's plans (perhaps especially in the United States). Sociologists speak of a "moral panic" when a normative concern so fires popular imagination that an irrational overreaction sets in. In some respects, an element of moral panic has distorted some instances of ethical research oversight. Reduced to abstractions and deprived of context, as principles tend to become in either a bureaucratic or vote-seeking environment, some reasonable guidelines have been juridically transformed into absurd restrictions: witness an American court ruling that a child's selective guest list for a birthday party discriminated against certain boys that were not his friends. Analogies to this sort of thing are not unknown in ethics adjudications, and can add complications to a sometimes challenging process.

## ETHNOGRAPHIC MEMOIR

---

An ethnographic memoir is a nonfiction text that recounts past individual experience as representative of a particular sociocultural group. These narrative constructions convey history through a personal lens and are subject to interpretation of viewpoint by the audience and sometimes by a self-conscious author. Ethnographic memoirs are a subgenre of life-writing.

### Conceptual Overview and Discussion

Ethnographic memoir usually represents dramatic or life-changing events as part of an individual's

life story. This narrative accounting lends itself particularly well to case study research. The reader arrives at the text prepared to learn the wider significance of particular historical events through an eyewitness account. In this way the ethnographic memoir is a form of testimony. Such testimony has a truth value similar to sworn statements in a law court. This dimension of reportage of what someone has experienced or witnessed makes the memoir compelling literature for case study research. At the same time, this feature of observation necessarily has limits. As Primo Levi explains in his memoir of Auschwitz internment between 1944 and 1945, *The Drowned and the Saved*, he is capable of sharing only what he lived, which is a partial experience of the Death Camp. His insight accordingly is specific to his work as a chemist and existence in the men's section of the camp. Levi's example is telling for another reason: Levi's recollections are told after much time's passing, when he has assumed a postwar position as a Jewish Holocaust survivor, scientist, and author of his experiences. Also, as he reckons, events that may have been misconstrued at the time of their occurrence have been synthesized in part on the basis of other survivor stories and are revisited on the basis of subsequent life experiences.

Commentary by Gary Weissman about Elie Wiesel's *Night*, his chronicle about being a teenager in Auschwitz from 1944 to 1945, speaks to the revisionary process of memoir. In Wiesel's case, several versions of his experience exist (ranging in length from around 100 to 800 pages), and there are different translations of the shorter French version *La nuit* (starting in 1960, the most recent in 2006). Purporting his view as shared by other critics of Wiesel's memoir, Weissman interprets the various editions of *Night* according to Wiesel's implied audience: the Yiddish text of 800 pages for Yiddish-speaking Jews and the slim French text of about 100 pages for Christian readers. Accordingly, the case study researcher gleans that rhetorical aims affect even how much information—or data—is given to different presumed audiences.

### Application

Not all ethnographic memoirs are so tragic as Primo Levi's and Elie Wiesel's, which reflect war-time trauma. More mundane memoirs bear on

case study research into ethnography while sharing important narrative characteristics with remembrances of more extreme events. Take Wayson Choy's *Paper Shadows: A Chinatown Memoir*, for instance. Choy's memoir is spurred by his finding out from a radio talk show that his "mother," the woman who raised him, was not his biological mother. This call to Choy, then in 1995 a successful novelist aged 57, led him to research his life growing up in Vancouver's Chinatown. His memoir has become a source of "knowledge" cultivated through ethnographic research and searching his memory and corroborating previously neglected glimpses of insight through discussion with other members of Vancouver's Chinatown community.

The chapters of Choy's text are structured around inserted photographs whose significance is then explained. Marianne Hirsch interprets the evocative use of family photographs in her *Family Frames: Photography, Narrative, and Postmemory*. Hirsch cautions against the presumed transparency of meaning in photographs. Nonetheless, photographs enrich a memoir, which shows the protagonist reporting on experience that may be unfamiliar to the reader because of distance across time and between cultures.

Suzette Henke draws insight for her investigation into life-writing from women's traumatic accounts. Foregrounding both significant limitations and opportunities for narrating important personal events, trauma theory increasingly informs the interpretation of memoir. Trauma study highlights the void between past and present and between extreme conditions and the everyday, but also opportunities for "narrative recovery" (Henke's term) from the recurrent memory of traumatic events through life-writing itself.

Some of the characteristics of memoir are shared with other forms of retelling, such as fiction. The personal positioning of the author makes her or him into a figure like a character in a novel. Descriptive aspects are drawn out and their significance given in actions, such as might happen to a picaresque hero. But the notion of the traumatic void most especially foregrounds the way significant people and events forming a community are being conveyed, often to another constituency that has an interest in learning more about the group represented by the protagonist. The narrator's text offers a bridge toward understanding the significance of events, which

supplements data in case study research. The memoir's narrator resembles the first-person 19th-century protagonist who provides information about unknown dimensions of life in addition to entertaining the reading public.

Ghosts in Choy's book are a motif symbolizing the haunting unknown. Though he does not see any ghosts himself, he remembers his Confucian neighbors and relations claiming to. Hence the text shows Choy from age 4 to 11 years witnessing a spiritual existence that he comes to value in maturity when he is prompted by the phone-in guest to the radio show to review events as he experienced them as a child, in order to glean insight into the shadows already forming around what he had then assumed were stable, clear understandings.

The reader follows the history of Chinese Canadians through Choy's retrospective journey of remembrance. *Paper Shadows* traces his family history back to the Sino-Japanese war, and forward to the arrival of Asian males looking for wealth in the Gold Rush and as workers building the Canadian Pacific Railway, and to the imposition of the Canadian 1885 Head Tax and the 1923 Exclusion Act. His memoir reveals a system of illegal documents used to circumvent controls on immigration and citizenship status after the railroad was completed, through the Second World War, and later when it was not possible to return to China.

Historical events in memoir are given individual significance. Discriminatory practices based on the Head Tax and Exclusion Act set an exorbitant price on entry into Canada or prohibited families wanting to rejoin male workers. Accordingly, many "uncles" (usually unrelated men constituting pseudo-family among other Chinese in Canada) influenced Choy's development and especially his knowledge of Chinese custom and history. Bearing actual family lineage and having living relations in China, Third Uncle had special influence on Choy's experience of Chinese values, cultural expression, history, food, and ceremony. Choy returns to his youthful adventures with these single men, especially Third Uncle, as he tries to draw out for himself and for the reader how he came to be raised in a close-knit community as an adoptee, unbeknownst to himself.

Significant for the reader, but understated by the author, is the fact that his adoption and the identity of his biological parents were known in Chinatown.

Even his lifelong friend Larry Wong knew, but did not hazard to tell him. The title of Choy's book *Paper Shadows* speaks to the flimsiness of documents. Wayson's "mother" assumed the identity of a married woman born in Canada who died in China in order to get into the country. Wayson himself owned a certificate of birth attributed to people whom he assumed were his birthparents, which was procured from a family friend, a midwife, who could register the birth. When the Exclusion Act was rescinded following the Second World War, Choy was then in a position to enter fully and legally into Canadian citizenship, unaware that his identity was fabricated and historically contingent.

### Critical Summary

Like the paper documents Choy's text reveals as discursive legal constructions, memoirs are telling personal stories that are necessarily subject to scrutiny by researchers, both in order to unravel the sociocultural and historical nuances of reported events, but also the affect of their narrativization itself. A form of life-writing, ethnographic memoirs overlap with trauma studies—bridging distance and degrees of experience through language. But not all ethnographic memoirs, such as Choy's story of a happy but naïve or uninformed childhood, are traumatic. When they are interpreted as narratives, memoirs are valuable first-person accounts that productively inform case study research into particular cultural experiences.

## ETHNOGRAPHY

---

The term *ethnography* has a double meaning: it refers both to a set of research methods used in field work and to the report presenting that field work, usually a richly detailed narrative account of people's everyday lives. Ethnographers develop close connections with the subjects and situations they study in order to grasp what the anthropologist Bronislaw Malinowski called the "native's point of view." By participating in people's lives, researchers develop an understanding "from within," describing situational members' lived experiences in detail and in depth, presenting the complexities of ordinary, everyday life as lived in particular settings. In many disciplines, such as public administration, public policy, and organizational studies, case study often refers to research produced using ethnographic methods, if not to ethnography itself.

### Historical Overview

Where a historical narrative of ethnography's origins might begin is a matter of reconstruction and interpretation. Although widely associated with anthropology and its 19th-century European origins, other sources can be identified. Some scholars locate its roots in ancient Greece, identifying Herodotus and Thucydides as proto-ethnographers because of the extensive detail in their travel accounts. Others look to non-Western worlds. David Deal and Laura Hostetler, for example, find a form of ethnography in bound collections of 18th-century Chinese hand-painted illustrations and handwritten texts that reveal how imperial China viewed culturally "other" populations—those minority ethnic groups living in frontier regions under imperial Chinese control. Still others oppose anthropology as the source of ethnography by

pointing to its use in European colonial administrative practices and by missionaries, explorers, government officials, military officers, and local leaders before becoming identified with that discipline.

Origins aside, both anthropology and sociology have a rich history of ethnographic writing. Malinowski is widely credited with giving modern ethnography its character by arguing that its principal method of collecting data should consist of extended and immersed field work among the people being researched, preferably in their native language and in collaboration with native researchers. This established participant-observer ethnography as the expected form, replacing the late 19th-century armchair ethnography that had based its analyses on the accounts of the earlier travel writers, missionaries, colonial officers, and others. In the so-called Chicago School in the United States, anthropology and sociology were initially linked and used the same methods. As they separated into two distinct disciplines, sociology took the name *participant observation* for its more urban-focused studies of life within national borders, whereas anthropology claimed the term *ethnography*, using the same participant observation methods, for its predominantly overseas studies.

Riding the waves of colonization, decolonization, and finally globalization, ethnography has also been transformed. In the first half of the 20th century, ethnography was often used in support of a religiously and politically motivated, evolution-of-civilization theory of cultural progress. Moving away from this view in the 1950s, ethnography became the vehicle for defending a cultural relativism that stressed the uniqueness of predominantly non-Western cultures in a culturally homogenizing world. From the 1980s onward, however, ethnographic findings were increasingly used to bolster a growing cultural self-critique in the West. In this process, the classic one-ethnographer—one-field (tribe, neighborhood, etc.) approach has gradually given way to the realization that in the (post-) modern, globalized world, ethnography must evolve into a multi-sited, interpretive endeavor, as "native cultures" can no longer be restricted to the confines of single spaces and set time frames. This broadening of the field has stimulated ethnography to evolve from an anthropology-dominated research instrument into a research strategy increasingly attractive across the social sciences, and it is

now practiced by many who have no formal training in anthropology departments. These much broader applications of ethnography raise the question whether, and to what extent, political ethnography, organizational ethnography, and other “marked” forms are developing distinctive sets of ethnographic practices reflecting the settings, actors, and theoretical questions that are of particular concern to them.

### Ethnographic Field Work

As with case studies, the ethnographic research process involve an interchange among evidence derived from different sources and methods of inquiry. The latter are the combined field research tools of talking to people (including conversational or ethnographic interviewing); observing (with whatever degree of participation); and close reading of documents (where relevant to the research question and setting). Research practices typically include engaging with participants in everyday talk and acts, a (participant) observing of routine activities as well as of less common rituals and ceremonies. Examples include hanging out with members of a street gang or shadowing managers in their day-to-day activities. Ethnographic research combines action (joking, working, chatting, hanging out) and proactive perception (observing, listening, reading, smelling). Using this distinctive set of methods and practices over an extended period of time, ethnographers are able to describe actors’ sensemaking across a range of circumstances, looking at what people do and what they say they do.

Analysis treats the symbolic representations of the meanings of the artifacts actors use in both speech and act—that is, the specific language, acts, and/or objects that embody and transmit actors’ sensemaking as they use them in creating, experiencing, and explaining social realities. These symbols include such theoretical categories as narratives, discourses, stories, metaphors, myths, slogans, jargon, jokes, gossip, rumors, and anecdotes found in everyday talk and text (symbolic language); rites and rituals, practices, customs, routines (symbolic acts); and built spaces, architectural design, clothing, and other physical artifacts (symbolic objects). Ethnographers work to make sense of situational actors’ sensemaking, usually through the latter’s own language and concepts

although theorized in terms of culture,” “identity,” “scripts and schemas,” “values, feelings, and beliefs,” “interpretive models of and prescriptive models for reality,” and the like—in short, as “meaning making.” Drawing on specific theoretical orientations, many ethnographers situate the minutiae of situational actors’ lifeworlds within their wider historical and social contexts.

Although ethnographic understanding develops through “immersion” in the field, “distance” is equally as important as “closeness” for an adequate understanding of the “natives” and, indeed, becomes crucial precisely when immersion takes over, so to speak. When the field becomes strongly familiar and “ordinary” to the researcher, it becomes important to avoid getting bogged down in a myopic gaze, seeing only the things that are simply “there” to be seen. Then, ethnographers need to regenerate a basic wonder about the unexpected and the counterintuitive of everyday “normality,” problematizing what they are observing in order to make what seems familiar and understandable strange again. Ethnography requires balancing the tension between an intimate familiarity with the situation and a detachment from it, being what Michael Agar has called a “professional stranger.” The ethnographer is, in these ways, cast in two roles simultaneously: situational participant and observing researcher.

### Meaning-Making and Ethnographic Textwork

Ethnography combines an orientation toward subjective experience and individual agency in everyday life with sensitivity to the broader social settings and the historical and institutional dynamics in which these emerge or are embedded. Drawing close to the ordinary communications of ordinary people on an ordinary sort of day while remaining surprised about it all enables ethnographers to describe the everyday lives of flesh and blood people. Like Sergio Leone’s acclaimed style of filming in *Once Upon a Time in the West*, ethnographic texts tend to alternate extreme close-ups that show detail by portraying persons with particular facial expressions, talk, gestures, and clothes with wide-angle or long shots that show panoramic views of the institutional context, the historical background, power relations, and societal discourses. Through reporting on researchers’ firsthand field-based

observations and experiences, ethnographic writing, as Clifford Geertz reminded us, has the capacity to convince readers that the author has truly been there. Providing detailed renderings of settings, objects, actors, acts, interactions, and circumstances, ethnographic texts place both author and reader at the scene, in the thick of things, conveying a sense of this “being there” to the reader.

In describing situational meaning-making, ethnographic research often challenges readers as well as researchers to question their taken-for-granted beliefs about the cultural aspects being studied and (re)presented. Drawing close to subjects and situations, ethnographers typically make explicit the often-overlooked tacitly known or intentionally concealed dimensions of meaning-making. Such ethnographies can, at times, have a somewhat critical, even raw—direct, unpolished, and sometimes shocking—quality, laying bare harsh and/or hidden social realities and exposing the entanglements of culture with power. Looking at the world with an unflinching eye, ethnographers may highlight the politics of sensemaking practices as they take into account the relative power of actors, the interests at stake, and the strategies pursued. To situational members, descriptions of routine, taken-for-granted ways of thinking and acting can often be both familiar and surprising, or even confronting, as they see themselves through someone else’s eyes. In revealing otherwise covert aspects of social life, ethnographies may at times even fly in the face of what people would like to hear or read about themselves and their communities.

Ethnographic research and writing can be informed by different ontological and epistemological presuppositions. These range from a realist (or naturalist) perspective that positions the ethnographer as an objective observer and “knower” of naturally occurring social phenomena, to a more interpretivist perspective that sees social realities as being socially constructed, with the ethnographer as fully part of these constructivist processes. These different methodological approaches to research become evident in the written texts: Does the ethnographer build on a realist or a constructivist ontological presupposition about social realities, and on an objectivist or an interpretivist epistemological stance with respect to how these realities might be known? Realist-objectivist narratives treat the evidence presented as a fixed-stage, univocal

account that holds out the promise of mirroring social reality. Constructivist-interpretive narratives emphasize the contingency and multivocality of what is being reported, treating social realities as collectively or intersubjectively constructed in an ongoing interplay between individual agency and social structure, in and through which individuals and structures mutually constitute each other. Publications by James Clifford, Clifford Geertz, George Marcus and Michael Fisher, and John Van Maanen in the mid-1980s highlighted the extent to which ethnographic texts have, in some respect of the word, created the subjects and settings they studied. Looking at ethnography as what Nelson Goodman called a “way of worldmaking” highlights its interpretive presuppositional character. This is leading to growing attention to the rhetorics of ethnographic (and other research) texts: the ways they are constructed and seek to persuade their readers.

### Interpretivism and Reflexivity

Interpretive ethnography builds on the understanding that the world that researchers study does not arrive pre-labeled and pre-theorized. This calls into play a heightened self-conscious awareness of the researcher’s role in “worldmaking”—creating sense during field work, deskwork, and textwork out of the settings, events, and actors being studied. Methodologically, a constructivist-interpretive perspective increasingly expects, and even requires, ethnographers to inquire into their own meaning-making processes. This heightened self-awareness—known as reflexivity—examines the ways in which their own persons (from education and training to experience to personalities to demographic characteristics) might be shaping the knowledge claims researchers advance with respect to their research topic: their positionality. Positionality also has a physical dimension, as location within a setting can enable knowing of one sort while restricting knowing about other dimensions. For some, especially those working from a more critical theoretical perspective, this means inquiring into issues of power in the researcher-researched relationship and the links between knowledge and power. By contrast with realist ethnographers, most interpretive ethnographers think of ethnographic knowledge as being

generated in research, rather than as data being collected or even accessed, and some treat research participants as co-generators of ethnographic knowledge. In this view, research knowledge (or truth claims) is situational, co-constructed through interactions with others in social settings, and reflective of researchers' and others' positionality with respect to subjects and settings.

### Critical Commentary and Future Directions

Outside anthropology, ethnographers often need to defend their methods against charges deriving from more quantitative, positivistically informed methods. These include its questionable (from that perspective) production of evidence, relying on the person of the ethnographer and the subjectivity of both ethnographer and participants, and what is seen by others as the lack of rigor, validity, reliability, and generalizability. An understanding of the phenomenological and hermeneutic presuppositions and the 100-plus years of philosophical argumentation underlying ethnographic truth claims refutes these charges handily, as writers such as Richard J. Bernstein, Mary E. Hawkesworth, Donald Polkinghorne, and Paul Rabinow and Michael Sullivan have ably demonstrated.

More practical challenges to ethnographic research today derive from two sources. Within anthropology, its traditional settings—isolated, self-contained, remote communities—are no longer as welcoming as they were in the past, and anthropology has begun to look to other fields, many of them “domestic” (or “at-home”) settings, hitherto the domain of sociology and other disciplines. These include public policy and other governance settings on the one hand, and various kinds of organizational settings on the other, including high-technology firms and other corporations, hospitals and other healthcare institutions, and various educational enterprises. Whereas anthropology has long regarded ethnography in such settings negatively, as “applied” anthropology, shrinking resources in other arenas mean that these kinds of applications are likely to claim increasingly serious attention.

This leads to a second kind of challenge, most apparent today in the hiring of anthropologists to do ethnographic studies for marketing purposes (e.g., in Intel, IBM, and the like). This is not so different

from embedding anthropologists among army troupes in Iraq and elsewhere in order to produce knowledge that the military can use to improve its own performance. Both undertakings are close in concept (although not in politics) to action research, in its various forms, which calls on researchers to devise projects that will benefit those they are studying, often with participants involved from the initial research design. The ethical questions raised by these practices have yet to be worked out.

A third development emerges from changing circumstances in the modern world that challenge the received understanding of ethnographic methods. This is clearly evident in everyday technologies that have redesigned work practices. Traditional ethnography is built on researchers' face-to-face interactions with participants; but organizations, work, and political and social life today are often based on mediated interactions, whether by telephone, computer messaging, or even virtual Second Life avatars. Ethnographic research needs to rethink its assumptions in order to accommodate these changes.

Ethnography's strength is to “see the world in a grain of sand” (slightly paraphrasing William Blake), exploring and exemplifying the general through the local and the particular. As the structure-versus-agency debates continue to carve up the social sciences, the combination of contextual analysis with an actor-centered approach promises to remedy the apolitical reading and acontextual qualities of many social studies.

## ETHNOMETHODOLOGY

---

Ethnomethodology literally means the study of people's social, cultural, and worklives or, as Harold Garfinkel put it, "members of a local social scene." In particular, *ology* means logic and *ethno* refers to people's culture. Ethnomethodology refers to the ways people create various identifiable actions, routines, or practices.

Over the years, the case study methodology has little by little affirmed its relevance in the social sciences and started to speak with a stronger and clearer voice. A striking feature of case study is its central emphasis on the object being studied. Case studies underscore situation-specific, concrete, practical, and context-dependent knowledge. Long ago, the Greek philosopher Aristotle emphasized the value of case knowledge and the importance and influence of cases and context in the understanding of human performance. The strength identified with the case study approach lies in capturing "realities" in great detail. The detail and particularities of the case can be recognized and depicted by ethnomethodology. Thus, ethnomethodology can be used as a mode of inquiry

in doing case studies. In particular, in the ethnomethodological tradition contextually grounded case studies can be successfully generated. Ethnomethodology began to be recognized as a research approach when Garfinkel, influenced by Alfred Schutz and Edmund Husserl, published his book *Studies in Ethnomethodology* in 1967.

### Conceptual Overview and Discussion

Ethnomethodology is characterized by its pursuit of experiential processes of human action verbalized through language. Driven by its epistemology and ontology about reality creation, the ethnomethodological perspective offers a way of conceptualizing the everyday work life. Drawing on such understanding, ethnomethodology emphasizes everyday life and the ways in which people cognize, make sense of, and verbalize their actions and make them accountable to others. Ethnomethodology places importance on people, their settings, their communicative acts, action-creation and action-taking.

### Key Concepts

Attending to human interactions and practices, ethnomethodology is predominantly concerned with the empirical study of the way in which people cognize and make sense of their work life within their environments. Garfinkel referred to the ways in which people use their own methods and capabilities of cognizing and sensemaking as *ethnomethods*. Ethnomethods privilege using one's own skills and embodied competence, for example, in various situations that involve thinking and acting processes and that occur largely in interaction and conversation. There are three key concepts helpful in building case studies and using ethnomethodology: reflexivity, interaction, and language-in-use.

#### Reflexivity

Ethnomethodology takes an interest in reflexivity, that is, in the reflective capacity of human actors. All actions are essentially reflexive, whether of those who are the object of the study or of those who are researching them. Ethnomethodology refers to human practices. It can more accurately be regarded as a way to reflect upon and uncover the context and the embeddedness of action. It also

reflects on time and local historicity. Historicity embeds past experiences and local history of the moment and instantiates human interaction.

### Interaction

In the ethnomethodological context, ordinary people's interactions are focal. Ethnomethodologists take an interest in the much routinized and deep structure of interaction. Focusing on human interaction as central, everyday life is seen as an accomplishment. That is done in the course of making sense, acting, followed by naturally occurring talk. The key to this insight relies on people's process of making sense of talk in conversation with others. Furthermore, achieving intelligibility in interaction with others relies on a reflexive and consensual understanding of action, indexicality, and reliance on use of language.

### Indexicality and Naturally Occurring Language-in-Use

Equally central to ethnomethodology as human interaction is the notion of language, and more particularly, ordinary talk: that is, language-in-use. For ethnomethodologists, meanings reflect indexicality, and are contextually grounded within social settings. Indexicality refers broadly to the type of code, grammar, or vocabulary that is shared among people in a certain country or region. In other words, it identifies with the embeddedness of language-in-use in which it is created and used. Indexicality takes an interest in the "rules" people employ to make sense of verbal interaction. Indexical properties of language-in-use may refer to something else or preconceptions and discern the logic of shared meanings, that is, words that are understandable for the members of a social or cultural group in a particular context. Language is understood as naturally constitutive of social life and strongly depends on the context and history of the place in which it is used. Ethnomethodology also seeks to uncover information and messages that are both not verbalized and verbalized. For example, to understand the meaning of a verbal expression we have to comprehend what has been said and how it has been said.

### Application

#### *The Cognitive Constituent*

Ethnomethodology is dedicated to a situated analysis of human practice and interested in the

self-expression of human interaction in the course of communicative acts. It also takes an interest in how people cognize and make sense of the situations and the environment around them. Given the diversity and compatibility of positions within the ethnomethodological domain, different lines of inquiry originating from the social sciences tradition make the view of human activities and practices broader. One such view turned our attention toward the constitutive properties of cognition. Among the proponents of these lines of inquiry are Aaron Cicourel and Jeff Coulter, to mention just two. Also Garfinkel's notion of "looking" makes use of cognition, involving a site-specific collective apprehension of what is or may be accountably visible, but going beyond what is merely visible. Accountability refers principally to what people actually do and say that make sense to others. Cognizing and sensemaking are the most unnoticeable and discrete human activities associated with embodied competence that take place in everyday life. For ethnomethodology, the consensual nature of cognition, sensemaking, and action-creation are constructions existing in the mind-sets of individuals. The use of the mind-set by individuals is usually contingent on the environmental circumstances of human interaction and communication. The cognition and sensemaking that actors employ in their accounts are largely concerned with subjectivity and the individual's point of view. Cicourel pointed to the need for "cognitive linguistic concepts" that involve processes of information acquisition, storage, management, and retrieval. These ideas were developed further by Coulter, who referred to these processes as "grammars of cognition," which he understood as linguistic frameworks on which cognitive concepts and verbal expressions rely. Basically, the grammars of cognition reveal consensual processes of sensemaking that are appropriately applied to the defined situation or used in everyday life.

### Critical Summary

Ethnomethodology is not an entirely homogeneous field and should be viewed as a subset of qualitative inquiry. However, it shows the broad praxical potential to build intelligible and reliable case studies. It suffices to say that the research tradition of ethnomethodology in its empirical orientation

has much to offer the case study approach. It turns our attention to lenses that we use while thinking and acting and reflects endogenous and contextually grounded life experiences. The uniqueness of this methodology consists of uncovering in vivo phenomena that lie behind and are connected to various kinds of accounts important in building solid grounds for case studies. It is these grounds that may enhance the reliability and accountability of a particular case. This basically points to the fact that ethnomethodology preserves the analytical orientations that case studies demand that connect all the details of the activities in hand.

## ETHNOSTATISTICS

---

Ethnostatistics is a new field of scholarship that undertakes case studies of the professional creation, use, and interpretation of statistics and numerals. Ethnostatistics addresses statistics used in scholarly research as well as the professional production and use of organizational information. To explore these aspects of quantitative sensemaking, ethnostatistics focuses on informal or folk knowledge and social activities needed to actually produce and interpret statistics. Informal knowledge and practices of statistics production are essential to create and use statistics but are not well codified or explored in professional

treatments of statistics. Three levels of ethnostatistics developed through case studies of statistics production and use are: producing statistics (level 1), statistics at work (level 2), and the rhetoric of statistics (level 3).

### Conceptual Overview and Discussion

The meaning of statistics needs to be understood so the distinctive domain of ethnostatistics is clear. Statistics involves theories and techniques to manipulate data. It is the occupational home of statisticians and quantitative professionals who teach, develop, improve, and use statistics. Second, statistics is a label for rule-governed calculations. Third, statistics refers to almost any numerical summary that is the outcome of rule-governed calculations. Statistics aims to produce better counting from a technically correct perspective.

Formal texts and training provide procedures and guidelines for creating statistics, yet little is known about how statistics are created and used by their makers and users. Ethnostatistics, outlined by Robert Gephart in 1988, is a new field of methodological scholarship that studies how statistics are actually constructed, interpreted, and used by professionals. Ethnostatistics emerged from ethnomethodological research into informal practices needed to enact measurement and to interpret measures in social and organizational research. Ethnomethodology demonstrated that formal accounts and practices of science fail to describe fully what scientists actually do—the content of scientific practice. Scientific practice relies in part on commonsense reasoning and practical choices. Ethnostatistics explores the commonsense reasoning and practical choices in statistics production and use.

To study tacit knowledge and informal practices, ethnostatistics investigates the activities in which statistics and measurement are locally produced and practically relevant. Ethnostatistics explores the immensely varied practices that terms like measurement and statistics gloss over. It produces highly detailed and vivid case descriptions of the locally organized production of statistical or quantitative knowledge. Ethnostatistics thus enriches our understanding of methodological aspects of quantitative social science and provides a qualitative perspective for understanding quantitative social research methods. Ethnostatistical

case studies thus assess quantitative research practices, challenge methodological conventions, and suggest improvements in quantitative research.

Ethnostatistics explores three levels of analysis. The first level, producing a statistic, uses anthropological techniques including observations and ethnography to develop case descriptions of the work activities of quantitative professionals as they create statistics. Ethnostatistics then undertakes a second level of analysis by putting statistics to work in computer simulations that assess underlying practical and technical assumptions made in producing statistics. These studies explore how alternative assumptions would influence outcomes and interpretations of statistical measurement in specific research contexts. Third-level ethnostatistics uses literary analysis to explore the rhetoric of statistics—how textual practices persuade readers that the statistics reflect truths.

### Application

#### *Three Levels of Ethnostatistics: Elaboration and Examples*

First-level ethnostatistics studies how statistics are actually produced and used. Observational techniques including ethnography are employed to develop thick descriptions of conversations and actions of statistics producers and users as they create, interpret, and act on statistical information. First-level ethnostatistics explores the “how” of creating quantitative knowledge by following approaches developed in ethnographic case studies of natural science. This approach involves following quantitative researchers around while they work and examining the contexts, informal work practices, meanings, and knowledge used to produce quantitative research. The focus in these case studies is on who said what to whom, how, when, where, and why during the creation of measures, numerals, and statistics.

An important example is provided by Jaber F. Gubrium and David R. Buckholdt who undertook field research in two human service organizations to learn how “hard” quantitative data are created by hospital staff. Staff at one institution sought to measure “fantasizing” behavior by patients to develop a baseline of normal rates of problem behavior. The research showed that hospital staff relied on observations of patients’ physical behavior

to recognize the existence of fantasizing—acts such as staring into space. But they counted or recorded only instances of fantasizing when it was displayed in actual verbal behavior. The researchers thus demonstrated that informal practices and ad hoc rules influenced decisions to count phenomena as psychological aberrations.

Second-level ethnostatistics uses simulations and statistical methods to test the usefulness, validity, and implications of technical and practical assumptions made in producing statistics. The distinguishing feature of second-level ethnostatistics is the concern with the intersection of technical and practical assumptions and the use of quantitative methods to understand how human and social features and contexts affect measurement outcomes, statistical results, and findings. For example, conventional regression statistics is a common tool in social science and management research. Pearson’s regression statistic assumes data are measured at the interval level of analysis where an underlying continuous variable exists with equal distances between categories. However, researchers in social science and management commonly employ a parametric strategy whereby they convert ordinal data created with Likert scales (e.g., “strongly agree” to “strongly disagree” type measures) into equal interval values by assigning sequential numbers to observations. Likert-scale produced data are inherently ordinal in nature, that is, they exhibit differences in ranking of categories but no underlying equal distance between categories. In quantitative research using the parametric strategy, such ordinal data are transformed into interval data and treated as interval data for analyses.

A case study of the adequacy of the assumptions of “parametric strategy” was undertaken by Gephart in 1983 who simulated different data transformations on one data base and examined outcomes. The study revealed that the parametric strategy created measurement distortions that violated assumptions of regression statistics and thus made the use of the parametric strategy questionable. This raises questions about the validity of much research in management and industrial psychology.

Third-order ethnostatistics treats scientific reports and quantitative communications as rhetoric. That is, documents that report statistics are treated as literary documents. Third-order ethnostatistics explores how literary practices are used to accomplish

meanings for statistics and to persuade readers about the truthfulness of the documents. It shows that interpretation and use of statistics are artful, rhetorical processes oriented to persuasion rather than strictly rational processes that report facts.

Jean Helms Mills, Terrance G. Weatherbee, and Scott R. Colwell in 2006 provided an example of how university documents, including Web pages, rhetorically compose interpretations of university performance. Performance was examined in terms of rankings done by the accreditation process of the Association to Advance Colleges and Schools of Business (AACSB). This ranking process created a large number of measures of institutional performance, but the researchers show how each institution highlighted a small set of measures favorable to the institution's reputation.

### Critical Summary

Ethnostatistics offers a new domain for case study research that is timely and significant in today's world. Thus while many scholarly researchers still rely on statistics to establish scientific "truths," ethnostatistical case studies have challenged such received truths by demonstrating how different statistical measures, measurement practices, and research procedures can produce inconsistent findings and conclusions. Ethnostatistical studies have also challenged the ways statistical information is selectively created and rhetorically used by institutional stakeholders to legitimate organizational policies and reputations.

Such critical case studies of statistics production and use assume greater importance where acts of corporate malfeasance such as the Enron case can be linked to aberrant construction of financial statistics and information. Indeed the global financial crisis has underscored the risky nature of economic forecasts and planning that rely on selective construction and problematic interpretation of statistics. Statistics construction and use has thus produced adverse social impacts and challenged public trust in key social institutions. Ethnostatistical case studies thus offer a well formed basis for critical studies of quantitative sensemaking in key institutions. Such studies can lead to critical reflexivity, enhanced validity in research, and improved policy options.

## EUROCENTRISM

---

*Eurocentrism* refers to a body of knowledge that has been used to interpret the histories and cultures of non-European societies according to the European experience. Embedded in present-day thought, values, and education, Eurocentrism is naturalized as common sense that underscores non-Western values and ways of knowing.

### Conceptual Overview and Discussion

Eurocentrism first emerged as a discursive rationale that justified colonialism, the process by which the European powers reached positions of hegemony. Historically, the term *West* has been associated with ideas, values, and ideals reflecting the prevailing views of Europe—perceived to be the center of the world. As a form of thinking, Eurocentrism still permeates and structures contemporary practices, representations, and knowledge even after the formal end of colonialism. Eurocentric discourses present history as a linear trajectory, and Europe and, more recently North America, as the center of progressive, historical, democratic thought and change.

Early Eurocentrism can be traced back to the Renaissance, during which learning approaches focused on the ancient Greek and Roman civilizations, which were significant to contemporary European civilization. The assumptions of European superiority increased with European imperialism in the 16th, 17th, and 18th centuries and flourished in the 19th century. Cartography was particularly instrumental in representing the progressive industrialized character of this region, which was contrasted with hunting, farming, and herding societies in other regions of the world such as the Americas, Australia, and Africa, which had been colonized by European empires. Even the complex civilizations of Mexico, Persia, Japan, and Peru were not considered as well developed as Europe and were often characterized as being static and traditional. European writers of this time constructed the history of Europe as a paradigm to be followed by the rest of the world through either colonialism or trade. By the 19th century, assumptions about European superiority had been translated into racial superiority.

By ignoring colonial relationships between the West and non-Western peoples and cultures, Eurocentric knowledge constructs progress and modernity as an inherent and unique product of European internal conditions. In contrast, non-Western societies' "backwardness" is constructed as a result of their specific evolutionary stage or level of progress and development. These hegemonic assumptions not only ignore history but also have had important consequences for the development of social knowledge. Eurocentrism has influenced the cartographic centering of Europe; the division of global history based on European events; the portrayal of history, philosophy, and arts as being exclusively European; and the use of race as a category to classify non-Western peoples.

Immanuel Wallerstein, who has critically assessed Eurocentrism, argues that although modern social sciences were developed in England, France, Italy, and Germany, the theories and methods based on European and North American materials have been used as universal tools. Social science has been Eurocentric throughout its institutional history: (a) It grounds European dominance based on its specific historical achievements; (b) it claims that scientific truths are valid across time and space; (c) it reproduces the view that

Europe's history is universal history; (d) it separates subject from object; (e) it constructs non-Western peoples as a European projection; and (f) it centers on progress, which became the explanation of the world's history and the motor of applied social science. These different dimensions have been part of notions of progress, the binary backwardness/modernization, and rigid demarcations between fact and value judgments and the production of knowledge.

Edgardo Lander, who has also written extensively on this topic, argues that Western scientific knowledge is understood to be *true*, *universal*, and *objective*, and that by definition all other forms of knowing are simultaneously characterized as superstition or folklore. Western knowledge rests on the construction of multiple dualisms such as reason and body, subject and object, masculine and feminine, and culture and nature, which serve to sustain claims of objectivity. In social science, the discovery of universal processes—which explain human behavior and hypotheses that could hold across time and space—has been pursued to produce value-neutral knowledge and reveal the "reality" in different regions of the world. Scientific knowledge and technological development are considered to advance in a linear direction toward higher levels of knowledge that can be used to transform nature.

### Application

Methodological Eurocentrism is based primarily on the assumption that Eurocentric concepts and explanatory and interpretative theories in the social sciences like economics, anthropology, and psychology apply to all societies across time and space and produce value-free knowledge. Early forms of research were less empirically driven and more normatively oriented. The move to empirical research happened slowly and was challenged because of its methodological conflict with a positivistic social science. Attempts to make empirical, particularly case study, research more scientific led to research standardization and the use of quantitative methods to reflect the Western paradigm. Standard social science requires that conditions of (a) problem definition, (b) hypothesis formation, and (c) data collection be met in order to produce reliable empirical research.

Eurocentrism is notable in the work of the founders of modern social science, such as Karl Marx, Émile Durkheim, and Max Weber, who were interested in understanding modes of production and forms of life from traditional to modern society. During the Cold War era, sociologist Talcott Parsons adopted Weber's contribution to distinguish between Western "universalist" social forms and "particularist" social forms of other cultures. Similarly, anthropologist Robert Redfield contrasted "folk" and modern "urban" society and "low" and "high" civilizations. Eurocentrism was the basis for constructing divisions or oppositions, where Europe and North America were perceived to be the model or reference for every other history. In comparative research, these constructs were useful to divide the world along binary oppositions such as First World/Third World and developed/developing/underdeveloped. These oppositions represented an evolutionary history and a set of attributes that distinguish the West from the rest of the world. One of the clearest examples of a Eurocentric worldview is Samuel Huntington's well-known book, *The Clash of Civilizations and the Remaking of the World Order*, where he characterizes the West and the rest in fundamentally conflictive ways.

The issue of the relevance of and applicability of Western or Eurocentric social sciences to non-Western contexts has been raised across disciplines. Critics have attacked the universalistic assumptions of Western sciences in favor of "indigenous" or local theories, approaches, and knowledge. Taking different cultural orientations as a frame of reference, researchers have been able to generate heterogeneous logic of the social phenomena and incommensurable concepts and for analyzing data. Recognition of multiple cultural orientations of research activities allows social scientists to develop culturally sensitive but less objective knowledge. Solutions of the multiculturalism problem are foundations of communications and truth claims in the domain of social sciences. The critique of Eurocentrism has emphasized multiculturalism and other perspectives and contributions.

### Critical Summary

As a body of knowledge, Eurocentrism has been used to understand and interpret the histories and

cultures of non-Western societies and remains central to the production of knowledge that is regarded as truthful, objective, and universal. Eurocentrism is based on hierarchical dichotomies, the universality of the European experience, the separation of body and reason, and the construction of others.

## EVENT-DRIVEN RESEARCH

---

Event-driven research is a dynamic research design that takes an evolutionary approach, focusing on people, processes, or routines and following observed or recorded events to their eventual outcome.

### Conceptual Overview and Discussion

Event-driven research identifies events and records what happens over time, linking the events to outcomes at some point in the future (see Figure 1). Each event sparks multiple possibilities; what is of interest is the choice that is made at these junctures, and the consequences thereof. Event-driven research is longitudinal in nature and may occur over long periods of time—months or years. The same events are followed over time, linking prior events to subsequent outcomes like a narrative unfolding.

In some instances, archival data can be used to harvest the information needed to formulate

**Figure 1** Event-driven explanations  
 Source: Aldrich (2001).

event-based explanations. Not all events will lead to noteworthy outcomes, and many in fact may result in nothing at all, or nothing of interest. Unexpected and unanticipated occurrences influence the eventual outcome and are impossible to predict but can be recorded as they occur, including how they influenced or changed the event trajectory and eventual outcome. As events unfold, it is possible to identify a temporal effect including how and when events influenced or affected an outcome, or how long it took for a change to be evident. In this type of research, a lot of information about small events is gathered because the consequences remain unknown. Opposing forces, both positive and negative influences, can be noted, including how the process or organization responds. Based on a Darwinian notion of evolution, event-driven research is interested in variation, selection, and adaptation. Of interest to the researcher is the variety of possibilities, which possibility was selected, and the adaptation that occurred as a result of choices taken and the consequences thereof. The evolution of organizations is not built upon a model of equilibrium or homeostasis, but on an understanding that events change the direction of the outcome in significant ways. The order that events occur is significant in event-driven research and becomes part of the narrative that explains why a course of action was followed, and when. Events and sequences of events are observed and described, and explanations in the form of a narrative are offered to help to understand the phenomenon that is being studied.

### Application

Event-driven research is illustrated by Linda Hill in *Becoming a Manager: Mastery of a New Identity*, which documents in a case study the story of 19 newly appointed frontline managers who are

followed through the first year on the job. Data are collected prospectively by the researcher, who spends time with each new manager, conducting interviews in person, shadowing the manager, and conducting phone interviews. The story of the experience and feelings of the managers is told using the managers' own words to create a narrative that describes how the managers defined their work and the transitions they experienced during the crucial first year. The "event" is the hiring of the employee; what occurs after that is observed and recorded, as events lead to other events until a predetermined outcome is reached or, as in this event-driven case study, a defined period of time has passed. This rich and descriptive narrative poses interesting questions for additional study and provides potential for organizational theorizing that could be explored further.

### Critical Summary

Event-driven research is interested in how a process unfolds over time and results in outcomes that become events themselves that lead to further outcomes as the narrative unfolds. The basic difference between outcome-driven research and event-driven research is the stance of the researcher and the research question being asked. In outcome-driven research, the researcher is metaphorically facing backward into the past, answering questions about "what" happened and suggesting plausible reasons for "why" it may have happened. Event-driven research imagines the researcher facing forward toward an unknown future, asking "how" questions and following an event through time to explain what outcomes occurred, and the subsequent events that resulted from decisions made.

## EXEMPLARY CASE DESIGN

---

In case study research, although a selected case occasionally is treated as a unique historical event (the emergence of the United States as a 20th-century superpower), more commonly it is treated as an instance of a class of comparable events (e.g., the emergence of the United States, Russia, and China as 20th-century superpowers). Sometimes (e.g., as part of a program evaluation) the results of a case study are expected to generalize to a set of comparable cases that exhaust a particular class (e.g., a specifiable group of schizophrenics in a particular hospital). At other times, the results are expected to generalize to a set of comparable cases within a broad or even theoretically infinite class (e.g., schizophrenics in general). Regardless of whether the relationships observed are expected to generalize to a finite or to a theoretically infinite class, the relations between the particular case selected for study and the class to which generalization might be expected should be—but often are not—articulated.

A frequent assumption is that the selected case is an exchangeable member of the class as a whole. That is, members of the relevant class are considered sufficiently homogeneous to warrant arbitrary, perhaps even random, selection of any member of the class for case study. When such uniformity can be substantiated, it is plausible that (a) each instance of the class possesses the features that define class membership; (b) the features that define class membership constitute—or are within—the boundary

conditions for the occurrence of relationships observed in the selected case; and (c) the relationships observed in the selected case will, therefore, generalize to the other instances of the class. In social science research, however, members of a class repeatedly—and perhaps generally—are neither homogeneous nor exchangeable, and, to that extent, attempts to generalize from a single case become problematic.

One way to address this issue is by selecting for study a case that exemplifies the relevant class. When an exemplar has been appropriately identified, the relationships observed in that particular case may generalize to other cases to the extent that they, like the exemplar, possess the features that define class membership. This claim requires clarification of what it means to exemplify class membership, that is, what it means to say that members of the relevant class possess the features that define the relevant class. So, if an “exemplar” is “a typical example” of a class, how is such “typicality” to be understood?

### Conceptual Overview and Discussion

#### *Exemplars From Univariate Classes*

When the relevant class has a univariate definition, the search for exemplary instances is reasonably clear. When a single, class-defining feature is either present or absent (i.e., when a dichotomous nominal scale is the basis for class membership), it is possible simply to select as exemplary a case in which the defining feature is present (e.g., an individual who has been widowed). Similarly, it is straightforward to select an exemplar from the maximally contrasting class that is defined by the absence of that feature (e.g., an individual who has not been widowed). And, by extension, when a single, class-defining feature identifies a deviant class, it is possible simply to select an exemplar in which that anomalous feature is either present (e.g., an individual who is unable to recognize faces) or, for a maximally contrasting class, absent (e.g., an individual who is able to recognize faces). Thus, when a class-defining variable is nominal and dichotomous, simplicity in the choice of an exemplar, including an exemplary member of a deviant class, is ensured by the inherently homogeneous character of the relevant class.

When a single, class-defining attribute is a continuous variable (i.e., when an ordinal, interval, or ratio scale provides the basis for class membership), selecting exemplars becomes somewhat more complicated. It is possible to (a) select an extreme case that has the highest value on the relevant variable (e.g., an individual with extremely frequent nightmares); (b) select an extreme—and maximally contrasting—case that has the lowest value on the relevant variable (e.g., an individual with extremely infrequent nightmares); or (c) select a normative case that has mean, median, or modal values on the relevant variable (e.g., an individual who reports mean, median, or modal nightmare frequency). In each of these circumstances, the selection of extreme, extremely contrasting, or normative cases according to their positions on a continuum is tantamount to the creation of homogeneous subgroups of which the selected cases are exemplary.

#### *Exemplars From Multivariate Monothetic Classes*

The search for exemplary cases is considerably more challenging when the class definition is multivariate. One step in this direction occurs when an exemplary case is selected using a multiclass nominal scale (e.g., basketball players, football players, baseball players, volleyball players). In these circumstances, it remains straightforward to select an exemplar from one of the classes that constitute the nominal scale so that its sole defining feature is present (e.g., an individual who is a basketball player). And, in these circumstances, class membership remains homogeneous—just as occurs in classes based upon a dichotomous nominal variable. However, selection of a case from a maximally contrasting subclass is not straightforward, because each of the other subclasses constituting the multiclass nominal scale has a different defining feature (e.g., an individual who is either a football player, a baseball player, or a volleyball player).

A more common multivariate challenge emerges when two or more features define the class for which an exemplar is sought. Regardless of whether the class-defining features are dichotomous nominal variables, continuous variables, or some combination of these, investigators often select cases that exemplify classes in which some combination of variables defines class membership. For example, it may be possible to select a case that exemplifies

African Americans residing in Massachusetts whose income is at the lower extreme of incomes in that state. Classes defined in this way can readily contain cases that are identical on all the variables that define the class. Just as the nominal variables (e.g., African American or not African American, resident in Massachusetts or not resident in Massachusetts) and the continuous variables (e.g., extremely low incomes) that jointly define the class can separately yield homogeneous classes, their conjunction also will provide a homogeneous class from which an exemplar can be selected. This possibility defines *monothetic* classes, that is, classes in which the cases are identical—or very nearly so—on all the variables that define the class.

The essentialist logic of multivariate monothetic classes provides the investigator with a seemingly compelling option in case study research: the invariant features of monothetic classes—and of their exemplars—accommodate the logic of operationalism that dominates contemporary social science. When the necessary and sufficient features that define a class can be operationally articulated so that members of the class are homogeneous, class exemplars can similarly be operationally identified for case study. However, phenomena in the social sciences may more often require the non-essentialist logic of multivariate *polythetic* classes for which there are no separately necessary and jointly sufficient features that define a class and, correspondingly, no separately necessary and jointly sufficient features to facilitate the identification of exemplary instances of the class. So, multivariate monothetic classes provide an important transition to consideration of multivariate polythetic classes. The importance of this transition is reflected in the controversies that surround discussions of typological studies in the social sciences. Multivariate monothetic classes are often what critics have in mind when they refer to typological studies as “merely descriptive.” Multivariate polythetic classes are often what advocates have in mind when they refer to typological studies as conceptually formative or generative.

#### *Exemplars From Multivariate Polythetic Classes*

The identification of exemplars that typify multivariate polythetic classes brings out a different set of issues than does identification of the exemplars

that typify multivariate monothetic classes. Whereas in monothetic classes each instance is identical to other members of the class on all the class-defining variables, in polythetic classes each instance is “merely” more similar to other members of the relevant class than to the members of other classes. A multivariate assessment of similarity, rather than identity, seems required by Morton Beckner’s classic definition, according to which polythetic classes entail a set  $G$  of features ( $f_1, f_2 \dots f_n$ ) such that:

1. Each member of the class possesses a large number of the features in  $G$
2. Each feature in  $G$  is possessed by large numbers of these individuals
3. No feature in  $G$  is possessed by every individual in the class

A class is called polythetic when the first two criteria are met and fully polythetic when all three criteria are met. In a fully polythetic class, the members do not have even a single feature in common; there is not even one feature that is necessary for class membership. Thus, it has been useful to consider the exemplar of a multivariate polythetic class as a case whose profile of features (a) most nearly resembles an idealized array of features (in  $G$ ) that are characteristic of the class (ideal types) or (b) most nearly resembles the normative levels of the features (in  $G$ ) that are characteristic of the class (normative types).

#### Ideal Types

For fully polythetic classes, one strategy for identifying exemplary cases is to select instances of the class that amplify and accentuate the features that are most nearly characteristic of the class. This strategy can be compared to John James Audubon’s attempts to depict the typical characteristics of bird species by magnifying their features in his drawings—approaching but never quite reaching the point of caricature. The numerical counterpart to this strategy is to use extreme values on the dimensions that contribute to the definition of a relevant polythetic class and, in this way, to articulate an ideal type that amplifies and accentuates the characteristics of the class. As in Max Weber’s discussion of ideal types, exemplary

instances in this sense are those that possess as many as possible of this idealized profile of features (or, stated differently, deviate minimally from this idealized profile)—even when instances of the class possessing the entire profile are rare or even nonexistent.

A case selected because it minimally deviates from the profile of features that identify an ideal type “represents” a class of entities even though it may be far removed from the central tendencies of that class. Choosing the ideal type as a basis for case selection involves theoretical decisions at two levels. First, this selection reflects commitment to a theory of concept formation and identification comparable to prototype theory in cognitive semantics. Second, it reflects a theoretical statement about the features of the ideal type that constitute the boundary conditions within which the relationships observed in the case study are most likely to be replicated. So, although it is possible to quantify the extent to which an instance of the class deviates from the ideal type, such quantification reflects theoretical commitments that are markedly different from those that are involved in the more typical assessment of departures from normative class characteristics.

#### Normative Types

A second strategy for identifying exemplary cases within polythetic classes is to select those instances of a class that deviate as little as possible from the central tendency of members of that class (i.e., from the class mean, median, or mode for each of the features in  $G$ ). The advantages of this approach become evident within broader consideration of the systematic classificatory procedures that rely upon numerical algorithms such as cluster analysis, as seen in the work of Kenneth D. Bailey. Cluster analysis requires (a) assessment of all the features in  $G$  across an array of individuals for which a classification (or taxonomy) is sought; (b) the calculation of pair-wise similarities (or dissimilarities) between each of the individuals in that array (e.g., Pearson product moment correlations, squared Euclidian distances); (c) submitting these coefficients to an appropriate classificatory algorithm (e.g., hierarchical cluster analysis, Q-type factor analysis); and (d) determining the features in  $G$  that differentiate each of the classes of individuals

emerging from these procedures. Minimal deviations from the profile of means, medians, or modes on the features in G that differentiate each of the emergent classes are then available as the criteria for selecting the exemplars of each class.

Although it would be possible to articulate an ideal type that amplifies the characteristics of a class derived from cluster analysis, ideal types are not usually attempted in applications of these numeric procedures. The reason is that, with the proper choice of similarity coefficients (e.g., squared Euclidian distances rather than Pearson product moment correlations), cluster analytic algorithms preserve both levels and profile information in the assessment of similarity between individuals and, hence, in the creation of classes. Thus, deriving ideal types from these classificatory procedures by amplifying the characteristics of a class might actually diminish the differences between the exemplars of different classes.

Another advantage of these procedures is that they require clear differentiation between (a) the features in G that differentiate the classes (and that facilitate exemplar identification) and (b) the features that are not in G but that may nonetheless be involved in the relationships observed in the case study. This differentiation enables the investigator to select from among three different design alternatives. One form of case study involves the examination of relationships between variables other than those that define class membership. The features that define class membership, then, theoretically constitute—or are within—the boundary conditions for the occurrence of relationships between these independently considered variables. In a second form of case study, relationships between features in G and features that are not in G may facilitate expansion of the class-defining features that belong in G. Thus, the case selected for study may enable further explication of the features that define the class. A third form of case study may uncover previously unknown causal relationships between the features in G, potentially contributing to articulation of Aristotelian “natural kinds” or Kantian “self-organizing systems.”

### Critical Summary

It is important to differentiate the orientation toward exemplar identification described here

from exploratory case studies in which no relevant class has been articulated in advance. The search for exemplars is grounded in the assumption that the investigator’s long-term objectives include the generalization of relationships observed in the case study. So, the notion of exemplar, at least as understood here, presumes some degree of articulation of the class to which those relationships might be generalized.

It is also important to recognize the differences in what it means for an exemplar to be “representative,” as demonstrated most clearly by the contrast between multivariate monothetic classes and multivariate polythetic classes. There is more than one way to be a typical member of a class—and choosing between them depends upon fundamental theoretical commitments.

## EXISTENTIALISM

---

*Existentialism* refers to a branch of philosophy that focuses on the individual and emphasizes process. Existentialism places an emphasis upon how we live our lives, not the nature of our existence. Even though it is arguably ancient in inception, existentialism naturally comes face-to-face with timeless issues such as humanism, freedom, and ethics. Taken as a broad area of inquiry, existentialism offers the potential for an ethics of freedom without subsequent nihilism. Case analyses that are rooted in an existential approach are interested in the freedoms and choices of individuals, with a

view toward understanding individuals' authenticity. The denial of destiny that is part of existentialism means that responsibility and an ethics of freedom will be at the heart of any case analysis that uses existentialism as a methodology.

### Conceptual Overview and Discussion

Existentialism is in some ways the forgotten philosophic child of the 19th and 20th centuries. Variouslly seen as morally bankrupt and nihilistic, a passing fad of the Left Bank of Paris, or superseded by the traditions of "The Post" (i.e., postmodernism, poststructuralism, postcolonialism), existentialism refers to philosophies that are grounded in the contextualized freedom of individual agents. Individuals are regarded as residing in the intersection of the past, present, and future with their own potential being the ambiguous site in which the intersection of self and freedom is played out, whether in good or bad faith.

Given all of the above, the label of being an existentialist can be contentious. Many associate the atheistic existentialism of Jean-Paul Sartre and Simone de Beauvoir with all existentialism, and the proto-existentialist Friedrich Nietzsche's famous pronouncement of the death of God seems to place him in like company. However, Søren Kierkegaard's early existentialism is somewhat compatible with a more theological perspective.

Existentialism is generally not regarded as the exclusive realm of the philosophers. Indeed, many of those who are seen as existentialists have contributed to the area of understanding largely through literature, with examples such as Sartre's novel *Nausea*, the works of Franz Kafka, and Camus' *The Stranger* being notable.

To move our discussion of an existentialist case methodology along, we need to come briefly to some broad and general sense of what existentialism is. This is no simple task, for existential philosophy is diffuse. We may, however, identify some common themes that run through existentialist thought:

#### *Individuals in Process*

Existentialism is focused upon the individual, and is commonly seen as being a humanist pursuit. Furthermore, the philosophy is interested in how

individuals exist, not what their existence is comprised of. The existentialist argues that, through our nature as beings of choice, existence precedes essence. In other words, we create ourselves through our choices. This might lead one to surmise that existentialism is primarily philosophical; far from it. Existentialism is seen as being practical; indeed, a way of living. Through arguing that we are the result of our choices, existentialism does not deny that we are shaped through our situation but rather argues that we can make something out of any given situation through our choices.

#### *Time, Death, and Absurdity*

Our experience of time is fleeting and of the essence, and for the existentialist this is important. Unlike the positivist notion of a universal time, existentialists argue that we experience time in different ways and depending upon what we are doing, thus adding a qualitative aspect to lived time. We are shaped by our past and yet at the same time we are more than just products of some sort of inevitability. We create our imagined future through our choices and so even our perception of the present is shaped through our free will. Because the decision to choose is in fact a choice, existentialism argues that these choices arise largely from nothingness and negation, now center-points at the heart of how we exist. Thus our own death is a lack of existence that is ironically similar to our existence of choices, which also arises out of nothingness. This renders our own death an absurd concept.

We are thrust into a world part way through the story, in which we now create ourselves. Without a metaphysical overseer, we have no singular external focus. Yet we are also aware of our impending nonexistence. Our absurd existence, which will end at some point, seems poignant; we cannot live the lie of pretending that we will live forever and yet to remain virtually paralyzed in indecision and fear creates a sort of premature existential death of the individual. Thus, an awareness of fleeting time is part of an existential perspective.

#### *Both Anguish and Freedom*

So existentialists argue that we live with a certain dread of something we can't quite fully identify. Anguish, anxiety, and nausea are all terms

that existentialists such as Kierkegaard and Sartre have used to differentiate these feelings from simple fear. Fear is related to something specific and tangible, whereas these other terms describe a sort of despair arising from a sense of choice without clear rules. We are free to make choices, but how to know what to choose? We thus have an emotional awareness that we are trapped by our own freedom. Conversely, not to feel this anguish is to be living in self-delusion by not being fully aware of how we create ourselves through our own choices. Freedom to choose, with the anguish that results from our awareness of such freedom, is central to existential case research.

### *Ethics and Responsibility*

Can we act ethically without engaging in the inauthentic behavior of denying ourselves our choices and thus our very identity? If so, how might we avoid nihilism and at the same time avoid a false sense of determinism, thereby ignoring our innate free will? These questions are at the center of the existentialist notion of authenticity.

To live authentically is to be true to our nature as creatures of freedom and choice. We are guilty of acting in bad faith when we deny our freedom to choose. We are responsible to ourselves, and yet we chose our very identity when we live authentically. How can this become an ethics, indeed what is our responsibility, when it comes to others?

Beauvoir offers us a useful way of examining this issue when she refers to the concept of “an open future” in which we are able to extend our own freedom through the expansion of the freedom of other. Our freedom is situated in our context, but we are more than our circumstances at the same time. Existential freedom needn’t be a mutually exclusive condition among individuals, according to Beauvoir.

### *Ambiguity*

At the core of existentialism we can see that ambiguity abounds. We are free, but we feel anguish; we create ourselves through choice, and yet we are affected by the context of our situation and by others. This is the nature of a process-based philosophy in which how we live takes center stage, superseding questions of the nature of existence. At

the same time that these unique, even quirky, aspects of existentialism seem challenging, we can begin to see the outlines of the strengths that such a perspective offers for case study research. What follows are three examples of case studies that use existentialism as a key part of their analysis.

### **Application**

To make best sense of how existentialism is applied to case study research, it seems useful to offer some examples of studies that employ a variety of different existentialist perspectives. Below are highlighted three case studies that use existentialism as a primary component in the analysis:

#### *Women’s Stories and Beauvoir’s Existentialism*

Peggy Wallace’s 2007 dissertation is a specific use of Beauvoir’s feminist existentialism to probe narratives of female chartered accountants or CA (in Canada; CPA in the United States). She first develops a feminist existentialist lens based upon key aspects of Beauvoir’s work found in *The Second Sex*, specifically highlighting the ideas of woman as the other, the notion of the independent woman, and the role of institutions and motherhood in women’s choices. By applying this theoretical lens to interviews with women concerning their stories of career choice as a CA or CPA, Wallace builds a case study of how women tell their stories regarding career paths and their acceptance of the role of choice as female CAs or CPAs. This particular study then makes two broad contributions. First is the application of a feminist existentialist philosophy to a case study. Second is to thereby probe the career narratives of women who are also CPAs or CAs. Because the literature supports the fact that many women exit potentially powerful career streams that likely lead to partnership in large accounting firms, the application of a feminist existentialism is especially revealing. This approach offers a detailed examination of how the social situation of these women as well as their acceptance (or lack of acceptance) of free will, choice, and the responsibility of such, intersect. Thus Wallace’s contribution is to probe how individuals’ suppositions about themselves and their world lead to their creation of their own identity as well as the product of their aware or unaware choices.

### *Work and the Meaning of Life*

Scott MacMillan makes extensive use of existentialism to probe the meaning of work. Initially starting with an exploration of the job career calling model, he explores how individuals make sense of their work lives. His dissertation is essentially comprised of 15 in-depth interviews with individuals who have made major changes in their working lives in their middle adulthood. Rather than use only one existentialist philosopher's perspective, MacMillan derives major themes and concerns from across a variety of existentialists in order to provide the lens through which he seeks to understand the interviews.

By taking a broadly phenomenological stance and specifically applying existentialism to the meaning of work for individuals who have made changes later in life, MacMillan is fundamentally exploring individuals and their search for an authentic life. This therefore also has implications for the study of notions of spirituality and work, in that MacMillan interrogates the implied compartmentalization of spirituality (and any subsequent attempt integrate it) to domains outside of one's working life.

This work offers a substantive methodological contribution through the application of a broadly defined existentialist perspective. Beyond this, Macmillan reaffirms the need to focus upon the individual in matters of meaningful work and the complexity of the domain. Practical implications concern the identified need for a link between applied reflexivity on the part of individuals and their making sense of their own working lives.

### *Existential Sensemaking*

Anthony Yue and Albert J. Mills make extensive use of existentialism in their 2008 case study of a mountaineering expedition in the Peruvian Andes. Through weaving a complex analysis of life and death decision making on the part of the mountaineers, the authors accomplish a number of goals: they offer an example of how Karl Weick's sensemaking approach may be informed by Sartre's existentialist ontology, how individuals may skillfully navigate their own identity construction; and they shed light on the process of organizing.

The authors consider intersections in how sensemaking, which is concerned with how we

understand past events and our own identity, interacts with the freedom of choice offered through an existential perspective. They then use a detailed examination of the book *Touching the Void* by Joe Simpson as a nuanced case that demonstrates the role choice plays in how we understand and create our own identity.

One key contribution of this piece is the technical linkage of existentialism and sensemaking into a heuristic that offers the opportunity to examine organizational processes without removing individual choice from the center of the analysis. Thus the authors create a robust tool for the researching of socially situated individuals who are both free agents and at the same time influenced by their context.

### **Critical Summary**

Existentialism refers to a group of philosophies concerned with how individuals live their lives. This interest is framed with the backdrop of understanding that our lives are finite, yet even within our limited lifetimes we have a great degree of choice. This focus naturally leads to quandaries of ethics that variously relate to how an individual makes correct, indeed ethical, choices and how these choices may affect others.

The utilitarian practicality of existentialism, grounded in a sense of comfort with ambiguity, interested in how we live our lives, and concerning a nonessentialized individual with choice and freedom, is useful as both a heuristic for case analysis and as a personal philosophy for the researcher. Unlike structuralists or positivists who contradictorily make free choices while tacitly alluding to their research subject's inability to do so (based upon the researchers' chosen theoretic perspective), existentialist researchers can explore how they themselves navigate such research decisions. This relative philosophic unity between what one seeks in one's research, how one goes about doing so, and one's perception of the subjects one studies is at the crux of the practical nature of existentialism. Thus we might argue that there is a certain honesty and authenticity in an existentialist philosophic perspective for the case study researcher.

## EXPERIENCE

---

Experience is an element of case study research that helps bridge the gap between data and presentation. Experience enables a researcher to draw out various elements of the data *and* the research process in order to create a more complexly nuanced case study.

### Conceptual Overview

Unlike other forms of research, research methods in the social sciences are often experiential. The act of doing research is as vital a part of the data collection as the data themselves. This is because many qualitative methodologies are firmly connected to the human aspect of data collection. In the social sciences, humans gather data from other humans, and both researchers and as subjects are capable of self-reflection. This differs from the nonreflective subject of the natural sciences. For many, this arguably presents a problem with the qualitative methods that are sometimes used in the social sciences to gather data on subjects capable

of self-reflection. If humans are interviewing and talking to other human beings, then the data can be, some would say, skewed by numerous factors that come into play when people interact. For others, however, such argumentation is weak since all research designed and carried out by humans—regardless of the method—is a human endeavor and potentially marred by various levels of human fault and inconsistency. The concept of “experience” then becomes vitally important as a part of the training, data collection, and teaching tools in case study research.

### Application

Experience in case study research can be viewed two ways. First, there is the experience of the researchers who complete the case study. Their experience includes both the act of collecting the data and the interpretation and theorization extending from the data. This experience, made available to others, is valuable in the process of creating comparative analyses, preparing for research in general (creating a research design/proposal), or teaching. Second, the reader's experience is important in terms of assessing and applying the case study. Through comparing and contrasting experiences, richer, more detailed case studies can be developed.

One of the benefits of illustrating one's own experience in case study research is that it can effectively allow others to see how an experienced researcher has dealt with various research settings. While research settings are rarely duplicated in the social sciences, having exposure to the specific research experiences of others usually means that some aspects will overlap with one's own research situations. If the experiences of others, as presented in case studies—or in the form of critical “stories from the field”—are made available, then the panoply of possible problems and outcomes in research becomes more easily imagined. In addition to the pragmatic value of research experience, researchers' experience in varied research settings enables them to interpret and analyze subsequent experiences of data collection. Part of social science research training is a fine-tuning of the individual's ability to “read” ambiguous or “messy” human interactions. Of course, the researcher is often part of these interactions, thus researchers

have to be able to manage their current social and emotional states while interpreting them in light of past personal research experience and the integration of knowledge from others who have worked in similar situations.

G. N. Appell's collection of very pithy case studies from anthropologists engaged in field work is still salient today. The volume centers on ethical issues that can arise during field work, so each entry briefly presents the situation and the ethical problem that the researcher faced. In some cases the anthropologist's course of action is revealed, but in others the reader is left without the "answer" and therefore must decide on the most acceptable decision. This kind of material makes for a very powerful teaching tool as it opens discussions that go beyond the pragmatics of methodological choices and into the realm of the very real and unpredictable situations that can arise.

The voyage of the research experience is wonderfully illustrated in Ruth Behar's monograph. Part ethnography part diary of a social scientist, Behar's work refuses to keep clear the boundary between herself as scientist of culture and herself as human being. What many readers might find unsettling—the openness and clarity with which she exposes her inner thoughts—others find refreshing. Finally, the experiences so many unknowingly share come to light and none of the data or the ensuing case study is marred because of it.

Researchers should be able to translate their experience into a useful research tool. Without proper reflection on our experiences, in terms of using them to develop salient case study examples, they can fall too easily into the realm of interesting anecdotal information. The value of experience comes in being able to assess and analyze it critically, and then transmit it to others. The experience researchers gain—as researchers and as interpreters of others' research experiences and outcomes—is a very valuable asset in terms of teaching and training. Part of the greatest challenge in teaching case study research methods is that the subtleties of the methods can really become understood only once people experience the methods themselves. Class time devoted to lengthy discussions of interview techniques, styles, and even potential problems can carry a researcher only so far. The actual act of gathering qualitative data is the way students begin to understand how

research methods actually operate in the field and to gain insights as to a method's relative strengths and weaknesses. Again and again social science students express that before employing case study research methods they had anticipated being "good interviewers" because they considered themselves social, personable, and interested in what others have to say. After having some field experience, they found they were confronted head-on with their shortcomings and successes in using qualitative methods. Therefore, one of the strongest teaching tools one has is the use of personal experiences in previous research settings.

### Critical Summary

In light of the nature of social science research projects and the subtle nature of many of the techniques, the informed and critical experiences of others become part of the roadmap enabling researchers to find their way more confidently. Case study research is ultimately useful in the development of research projects and in the classroom because of the successful translation of researchers' experiences.

## EXPLANATION BUILDING

---

In case study research, an explanation—a good, successful, satisfactory, adequate, or acceptable explanation—is intended to act as an answer to a specific research question. What counts as an explanation depends on the interest of the

researcher. Contrastive explanation is particularly valuable in case study. It shows why one thing rather than another (which might have been expected) occurred, or why one explanation of a given event is more acceptable than an alternative. One explanation of why a sports team does well over a season might be that it possesses better players than other teams; an alternative might be that the coach is so effective that he or she can get mediocre players to perform consistently at their best. Analysis of successful teams might lead to the conclusion that one explanation was comparatively better than the other.

### Conceptual Overview and Discussion

The following examines the major considerations in building an explanation by addressing these questions: What is the relationship between explanation and understanding? In what sense is explanation objective? How do the questions asked influence the explanation? What is the nature of causality? How does a contrastive explanation provide benefit to a case study?

#### *Explanation, Understanding, and Objectivity*

To explain something means to contribute to fostering an understanding of it. Someone who can provide an explanation of something demonstrates that he or she understands it, but creating an explanation will also contribute to others' understanding.

Ludwig Wittgenstein's discussion of word games suggests that a major part of understanding something is that a person can accommodate it in his or her worldview, that complex of knowledge, beliefs, and values that is an individual's internal representation of what the world is. We avoid the apparent subjectivity of our individual worldviews because we have ideas in common with other people. Ideas shared with others possess objectivity. Thus we can share understanding through explanations that are related to commonly held ideas about the world. When such commonly held ideas are used explanatorily, they escape from subjectivity.

#### *The Research Question*

Posing a specific research question is fundamental to explanation building. An explanation does not

exist in and of itself; it explains *something*. The formulation of the question identifies the interest of the researchers, the aspects of the case they are concerned with, and the direction of the research. It also suggests what would provide a satisfactory explanation.

A research question often concerns an event that occurred and that is not understood. Lack of understanding suggests that some other outcome was expected, so the question often implies an unstated "rather than something else." For example, Why did the Soviet Union place strategic offensive missiles in Cuba (rather than directly negotiate with the United States for the removal of American missiles in Turkey)?

#### *Causality*

The question "why A?" or "how did situation A become situation B?" may invite a causal response. A scientific understanding of causality is "mechanical": effect irrevocably follows cause. When we explain, for example, how lightning kills people, the outcome is a causal chain that is an inevitable result of the laws of physics. Such a deductive-nomological explanation is usually not feasible in human affairs because human actions are initiated by ideas and result from free will. As a result, the main mode of reasoning in explanatory case study is inferential and inductive rather than deductive, and causation is construed more broadly. We identify actions or ideas that have a strong causal influence on subsequent events as causes.

It makes sense to us to say that Hitler caused the Holocaust. In explaining how he did so, we would include the key Wannsee Conference in which the practical details of how to kill 11 million people were ironed out in what became an agenda for action. But this would not have occurred if Hitler had not become chancellor of Germany in 1933 and subsequently influenced others to accept his views and so create a society in which Jews were dehumanized and the unthinkable became unexceptional.

#### *Contrastive Explanation*

The contrastive explanation takes two forms. It may show that one explanation of a given situation is preferable to some other explanation. Alternatively, it may show why one state of affairs obtains rather than some other state of affairs.

As noted above, research questions often contain an implicit “rather than” clause. Because an anticipated or expected occurrence did not materialize, it is hypothetical or counterfactual. The explanation of what did occur is contrasted with the explanation of what might reasonably have been expected to occur.

Contrastive explanations are important because they can enable us to identify how the factors that influence the actual outcome differ from the factors that would result in some other outcome. John Stuart Mill’s method of difference may be exploited when we identify that two different circumstances are the results of similar chains of causal influences and we infer that the difference in outcomes is largely due to the differences in the causal chains. Thus we recognize which factors had a particular influence on the outcome.

Not all explanations can be contrasted; they may be incommensurable. In such cases, if one explanation is to be preferred, its selection may depend on nonexplanatory factors such as the interest of the researcher. If alternative explanations are not commensurable, the acceptance of one may not require the rejection of the other.

### Application

Ted K. Bradshaw’s study of a military base closure provides a straightforward example of a contrastive explanation. Received wisdom was that the closure of a base would have major effects on the local economy. Lost jobs, falling house prices, and less money spent in local businesses are expected. This did not happen when Castle Air Force Base closed. The cleanup of the base itself created new jobs; jobs that had been held by family members of military personnel became available; retail sales grew (albeit more slowly than otherwise expected).

Received wisdom provided an explanation of what was expected, and suggested what data might be collected to support it. Because the data collected did not support received wisdom, the latter clearly provided an inadequate explanation. Bradshaw had to create an alternative contrastive explanation to show *why* the expected disbenefits did not occur.

Graham Allison and Philip Zelikow introduce their explanation of the Cuban missile crisis by

identifying three models that were considered as the basis for an explanation of the crisis.

The rational actor model is a game-theoretical analysis that holds that the crisis was a game of chicken between Kennedy and Khrushchev in which one player’s move is entirely determined by the other player’s previous move(s). The organizational behavior model is that there are a number of semiautonomous groups within (and without) government, each with its own distinct interest in the situation, and that these groups produce decisions that are channeled upward and in turn influence presidential decisions. According to the government politics model, any government decision is a result of political bargaining between factions with different degrees of power, and in which interests are traded and favors given and called in. Each one of these models represents a particular academic discipline (game theory, organizational behavior, and political science) and shows how the interest relativity of the researcher(s) will favor a particular explanatory model.

In this well-known case, the authors demonstrate that any one explanation is not conclusively superior or preferable to others, and that they all inform aspects of the crisis. A more complete explanation than is provided by any one model is given by an aggregation of the three models, despite the interests of researchers (game theorists, organizational behaviorists, or political scientists) to provide complete explanations from their own fields. It is also possible that another explanation entirely, such as one focusing completely on the psychology of Kennedy and Khrushchev, may be more comprehensive.

### Critical Summary

Explanation building is concerned with finding a robust explanation of why a particular state of affairs exists, often contrary to expectations. The expectations may be based on a theory/model or on observed previous similarities. This contrastive explanation requires the researcher to describe a hypothetical explanation and to show how actual causal influences differed from those projected by the model. A study that attempts to contrast explanations will not necessarily find that one explanation is preferable to another, but the contrasting explanation provides a methodology for case study

research that will likely lead to the determination of an acceptable explanation.

## EXPLANATORY CASE STUDY

---

Using both qualitative and quantitative research methods, explanatory case studies not only explore and describe phenomena but can also be used to explain causal relationships and to develop theory.

### Conceptual Overview and Discussion

Case studies are often lumped together under the rubric of qualitative research and are frequently confused with methods such as ethnography and grounded theory as well as those of quasi-experimental research. In fact, explanatory case studies are distinct from all of these, and unlike most qualitative research that is employed to explore certain phenomena, explanatory case studies can be employed to explain phenomena.

Explanatory case studies should consist of an accurate description of the facts of a case, considerations of alternative explanations, and a conclusion based on credible explanations that are congruent with the facts. A major proponent of using case studies to explain phenomena has been Robert Yin.

The central feature of any case study is the intense focus on a single phenomenon. In investigating this phenomenon, researchers must be concerned with all possible sources of data that may shed light on the phenomenon. Therefore, case studies should not be directly associated with any one type of data collection. Consequently, the design should be driven by the needs of the case study methodology, not by the requirements of any one type of data analysis. This is equally true in explanatory case studies.

The most difficult part of conducting any case study is defining the case. A case that isn't well defined can lead to findings that aren't actually about the case but rather something else entirely or, in the case of multiple case studies, that the individual cases are not in fact comparable. Using common terms to define a case can also be problematic in that investigators may understand different things by the same term. It is critical that investigators describe the case clearly in language that everyone understands to mean the same thing. Essentially, in order to develop an explanation the investigator needs a clear understanding of the phenomenon or phenomena under investigation. See for example G. T. Allison's classic study of the Cuban missile crises, where he very clearly defines the phenomena under investigation.

### Application

Explanatory case studies should follow an outline that clearly indicates the priorities to be explored. Some type of flowchart or logic model that portrays the patterns to be investigated is necessary in order to ensure that the investigation stays on track. Completing such a logic model in advance of the start of the research can guide investigators as to what topics or questions need to be explored.

While following an outline is critical to the design of a case study, such forward thinking does not mean that the investigator is rigidly stuck following such an outline. A key feature of an explanatory case study is for the investigator to remain

open to new discoveries during the process. Similar to a crime scene investigator using strict scientific methods in a crime scene investigation yet staying open to all possibilities affecting the crime, researchers using this method must also stay alert to all new possibilities. However, in order to prevent biasing a study by allowing such discoveries to modify the design, researchers may have to revisit the entire design should such a discovery call into question the earlier work. This iterative process is a strength of the explanatory case study as it ensures that the explanation is arrived at independent of any methodological biases.

Investigators may also want to examine rival explanations as a strategy for enhancing the credibility of their own findings. Examining another study's explanation of a phenomenon and showing how it fits or does not fit with their own shows that the researchers are open to all possible explanations and have indeed explored all possible data sources. The key to this process is to overcompensate, to saturate, when collecting information to support a rival theory, thereby avoiding the perception of bias. Allison, for example, organizes his investigation by positing three possible models of foreign policy that could be used to explain the crises.

Case study research has always required acquiring information from multiple sources. Such triangulation occurs during data collection and may lead to data sources not previously considered. This clearly is an asset as it will increase the veracity of any explanation.

A key issue in explanatory case study research is to distinguish between the actual evidence and the investigators' interpretation of the evidence. Historically, it has been very difficult to distinguish between the two as the results have been presented in narrative form created by the investigator. This has led to the criticism that investigators are presenting only the data that support their own interpretation. It is critical that researchers present their findings in such a way that the reader can clearly follow the logic employed to arrive at the explanation. See, for example, A. E. Dale's investigation of the patient's quality of life.

Generalizing from case studies has long been considered a problem. However, being able to generalize is critical to arriving at explanations. It has been suggested by Robert Yin and others that the solution is to consider each case study as a unit

equivalent to an experiment and then to conduct multiple case studies just as multiple experiments are conducted. The problem of generalizing the results is the same in both quantitative and qualitative research except that case study investigators are not driven by or constrained by an existing theory. Rather, they are trying to develop a new theory or a new explanation.

### Critical Summary

Explanatory case study research clearly has a role to play in investigating and explaining complex phenomena that may not lend themselves easily to quantitative research methodologies. The flexibility inherent in case study research provides an excellent counterpoint to the rigidity required in most quantitative research methods. Criticisms of this method are limited mainly to the difficulty in accurately accumulating and analyzing such voluminous amounts of data. Nevertheless, the explanatory case study methodology, employing all of the above factors, can be employed to test theories and hypotheses and to set the stage for richer, more in-depth acquisition of knowledge.

## EXPLORATORY CASE STUDY

---

The exploratory case study investigates distinct phenomena characterized by a lack of detailed preliminary research, especially formulated hypotheses that can be tested, and/or by a specific research environment that limits the choice of methodology. This form of case study is very often applied as a preliminary step of an overall causal or explanatory research design exploring a relatively new field of scientific investigation in which the research questions have either not been clearly identified and formulated or the data required for a hypothetical formulation have not yet been obtained.

### Conceptual Overview and Discussion

Since exploratory case studies are by definition often applied in a research context that is not clearly specified and still requires data for the formulation of valid hypotheses, their broad concept provides the researcher with a high degree of flexibility and independence with regard to the research design as well as the data collection, as long as these fulfill the required scientific criteria of validity and reliability. An exploratory case study is therefore not limited in terms of its qualitative or quantitative specificity. However, it is this ostensible high degree of potential options that causes the critics of such studies to question their relevance in terms of research that goes beyond the elementary formulation of hypotheses leading toward continuative research, instead of considering this a valuable methodological approach in itself. It is here where the parallels between exploratory case study research and grounded theory become obvious.

Since the primary aim of exploratory case study is the exploration of the hitherto unknown—in terms of the scientific status quo—it benefits most from cases that make the characteristic investigation field issues easily apparent. An approximate transfer from extreme observations, including single case studies, to the general is common practice. This is especially relevant when the researcher is faced with certain limitations in terms of data access and/or a restrictive research environment in terms of the analyzed phenomenon; that is, where the preliminary collecting of data for eventual

generalization is a precondition to develop successive causal studies.

Robert Yin, probably the most prominent and seminal author with regard to case study research in general, defines exploratory case studies as a means to define the necessary questions and hypotheses for developing consecutive studies. He therefore highlights case study research's supportive role in developing continuative social research in general. This includes single and multiple case studies, which can also test proposed research approaches and open possibilities for a variety of subsequent research designs. Yin furthermore emphasizes the controversial status of this particular type of case study research within the scientific community compared to, for example, descriptive or explanatory case studies. The main reason for the controversy caused by exploratory case study is its intuitive approach, which is also its biggest advantage when phenomena are studied that are as yet unrecognized.

Although this definition is in accordance with the position stated in the previous sections, it ignores the usefulness of exploratory case study research in the study of social phenomena in their original context, especially when doing so by other means is difficult or impossible. This might be relevant for other kinds of case study research as well, but it is a predominant characteristic of the intuitive and flexible exploratory case study.

### Application

Apart from the general elements common to all case study research (detailed, e.g., by Kathleen Eisenhardt), exploratory case studies are generally distinguished by the absence of preliminary propositions and hypotheses. Identifying these very often is the actual purpose of the study instead of being its origin. Consequently, clarifying the rational assumptions, the direction of the research and, most important, its purpose is crucial to the eventual success and outcome of a rigorous study on which subsequent research can be built. If, for example, the research protocols have been adapted during the study, this has to be clearly stated and justified to ensure maximum reliability.

Yin provides useful examples of the exploratory case study's application. In a study on the sustainability of innovations in the urban service

sector, the exploratory research was undertaken within the pilot test phase to answer the question regarding the innovations and services on which the research had to focus and the means that had to be applied, that is, the kind of research framework that had to be developed and appropriate measures that could be operationalized. At this point, the researchers had a broad understanding of the lifecycle of innovations, which ranged from the introduction to the actual routinization of the processes. However, an empirical research could not be built on this alone. Overall, the study included 12 cases and a telephone survey of 90 additional sites. The data collection and analysis became an iterative process: Every time new findings required it, the actual research protocol was altered and adapted to meet the specific site and case requirements, thus reflecting the intuitive nature of exploratory case studies. Eventually, six innovations and three services were identified that allowed the structuring of the necessary research framework and the formulation of hypotheses on which the subsequent empirical research could be based.

A typical example of exploratory case study research justified by the absence of preliminary research as well as a difficult to access research context can be found in Christoph Streb's study of aging workforce management in the automobile industry. The demographic aging of societies' effects on the age pattern of the available workforce is an emerging topic and an issue that has scarcely been researched. This is especially true with regard to blue-collar workers in industries such as automobile production. The researcher consequently decided on an exploratory case study in a large automobile plant due to the lack of existing propositions and hypotheses but especially due to the sensitivity regarding the potential constraints of the growing number of older blue-collar workers and the resulting challenges when entering the case site: In times of increasing productivity and resulting human resource overcapacity at the researched plant it was feared by some responsible managers that constrained older employees might be the first to be laid off in order to avoid resulting costs from overcapacity and physical constraints of the older workforce. The conducted research was seen as a potential threat by some. Deciding

on a highly flexible and adaptive exploratory case study approach allowed the researcher to develop the necessary definitions, frameworks, and hypotheses for the subsequent explanatory research despite these challenges.

### Critical Summary

As described above, exploratory case study research is often regarded as little more than a preliminary step toward specific and focused causal research to generate required hypotheses. Its degree of flexibility, for example in terms of data collection methods, and its—by definition—lack of specific, theory-based prior assumptions are often not considered a strength but a weakness. There is, of course, always the risk that these characteristics could be an excuse for inadequate and unscientific studies. Nevertheless, criteria such as validity and reliability, which are applicable in all research methods, should serve as clear indications of the soundness of the research. Such criticisms might, however, result in a general underestimation of the potential value of an exploratory case study, since this method can provide value beyond the provision of a hypothesis. This is especially true with regard to emerging topics and fields of research as well as difficult to access research settings.

## EXTENDED CASE METHOD

---

The extended case method (ECM) is an ethnographic research method that focuses on a detailed study of concrete empirical cases with a view to “extract” general principles from specific observations. Typically, a researcher would participate in and observe a number of related events and actions of individuals and groups over an extended period of time. The researcher would then construct his or her (ethnographic) story and theorize about a social phenomenon, rather than start with a theory to explain an empirical reality. ECM is at once a method of data collection, analysis, and theory building. Both the conceptualization and the application of the ECM have changed over time. This entry describes the emergence and development of ECM, its insights, and limitations and its potential areas of application.

### Conceptual Overview and Discussion

The origin of ECM goes back to the 1940s. It was the then newly established Manchester School of Social Anthropology, led by South African-born British social anthropologist Max Gluckman, that invented and used the method to describe and theorize how everyday practices in specific places were related to larger structures and processes. Gluckman, and his students such as V. Turner as well as his associates, including J. C. Mitchell, observed and analyzed the actions of individuals and groups to arrive at an understanding of social structure. For example, Gluckman used an event of the ceremonial opening of a bridge in Zululand, South Africa, to illustrate the extent to which Zulus and Whites were involved in a single system rather than being solidly separated as Blacks and Whites. The Manchester School called events such as the bridge opening ceremony “situations,” and their analysis of such situations was therefore referred to as situational analysis. Thus, sometimes the term ECM is used interchangeably with situational analysis, which is itself sometimes referred to as processual analysis by Gluckman’s students, for example, B. Kapferer.

It was not the use of case study as such but how the case studies were used that gave ECM and situation analysis a place of pride in the history of

qualitative analysis. The Manchester School used extended cases separated by time and micro-contexts to produce an image of social life, even of village communities, that is messy, conflictual, and changing. Such a view of social life upset the seamless equilibrium model of society that was established by the then dominant paradigm of structural functionalism that thought of society as generally orderly with every part (persons, institutions) playing its role to ensure the overall smooth functioning of the system. In contrast, ECM and situational analysis focused ethnographic attention on “trouble cases” such as situations of conflict and individual actions that did not conform to presumed societal norms. By doing so, Gluckman and his students opened themselves to the messy actualities of social life and thus ventured into the possibility of discovering unforeseen insights on social processes.

Their generalizations emerged from an examination of series of interconnected case studies, not from the application of a grand theory. Thus, theory was built from the ground up, as it were. Looked at from today’s perspective, the Manchester School’s approach remained by and large structural analysis and thus did not fully allow the discursive practices inherent in case studies, but it clearly opened up an analytic horizon that found its fuller expression in later works.

More recent (1980s–present) elaboration and application of ECM has been influenced by the emergence of poststructuralist works such as that of P. Bourdieu’s practice theory and its emphasis on agency. Where the Manchester School used ECM to highlight the effect of extralocal factors such as colonialism on African society, recent elaborations sharpen the method’s relevance for shedding light on the micro ramifications of such postcolonial practices and global forces as free market ideology and how these affect local cultures.

In what looks like an extended ethnographic follow up of the Manchester School’s African ethnography, Michael Burawoy, for example, uses ECM in his study of the copper industry in postcolonial Zambia. Burawoy produced a fascinating ethnography that illustrates the interconnection, albeit unequal, between the individual black Zambian workers, White industry managers, the newly independent Zambian state, and the world copper market controlled by advanced capitalist nations. Burawoy arrives at this big picture by

connecting his extended (participant) observations from various concrete situations. The recent reworking of the ECM, like that of Burawoy, is in tune with the postmodernist emphasis on reflexivity that became a general trend in the social sciences, most strikingly since the 1980s. As it applies to sociological and anthropological research, reflexive ethnography seeks engagement with the subject, as opposed to objectivity (note that the postmodernists think objectivity is an illusion).

Applying ECM reflexively would prompt one to be aware of the effects of power on the research context and raise the question of who sets the research agenda and whose interest research serves. In the conventional anthropological research context where the researcher is generally a White (often male) and the subjects are generally non-Western natives, the need to be aware of the effect of power on the research is very acute. In such contexts, the relationship between the researcher and the researched is colored by the history of power differential between White colonialists and natives as well as the contemporary context of tourism and NGO interventions where a White person comes to these villages generally as a rich and powerful person vis-à-vis the villagers or unemployed city youth.

But the contemporary research context is changing and the actors are more diverse. Nonetheless, in a qualitatively different sense the power question remains important in research contexts where the researcher might be a non-Western man or woman doing research in his or her own country. For example, Data D. Barata, a male Black African, recalls his research encounter in his native Ethiopia where he would appear relatively more powerful vis-à-vis his villager informants. As a university graduate, at times employed by a Western institution, he was materially richer than the average villager or unemployed youth. But part of the perception of power of the native researcher by the researched comes from associating such researchers with state bureaucrats who strongly affect the lives of villager citizen subjects. In such a context, an extended stay with one's informants following ECM is crucial to win the trust of the informants.

### Application

The application of ECM entails mapping out the power-laden interaction between the local, the

national, the transnational, and the global. While there should not be any illusion about the power disparity between actors differentially situated in the local–global gradient, every actor is imbued with agency—the ability to influence to a lesser or greater extent what actually happens on the ground. Therefore, an application of the ECM in the contemporary context would entail documenting how the global, the national, and the local are mutually constitutive of each other.

The adaptation of ECM in recent years has gone beyond academic practices of sociology and anthropology. The method has been found relevant in the field of consumer research studies, especially in areas such as consumer choices, use of new technologies, consumer satisfaction, consumer emancipation, cultivation of consumer identity through consumption of some brands, and generally to understand consumer culture. This emerging area of application is attracting enthusiasm, especially from those who are interested in sharpening marketing tools.

### Critical Summary

Trying to adapt or apply the ECM as an ethnographic method to the fast-paced life situation of late capitalism, one has to be aware of some limitations of the method. ECM is not intrinsically a rapid method. Therefore, it may not satisfy the needs of anyone looking for a “hit and run” method of data collection or analysis. Also, applying ECM and participant observation in a hastened context of the capitalist urban milieu may not give the researcher sufficient time to get past the initial resentment of intrusion that is often felt by any person or group of an “outsider” (posing as researcher) wanting to observe their lives that closely. The pressure to quickly produce results also comes with dwindling funding for an extended observation of social situations.

These limitations notwithstanding, ECM as an ethnographic method of doing extended observation of human interactions, choices, and events to understand how the human world works has emerging potential of wider application. Global interconnections are real and further deepening, even though the world is still experienced for the most part locally and concretely. Therefore, an extended observation and analysis of these concrete

events and diversely situated experiences offers great promise for making sense of an otherwise truly complex world.

---

## EXTENSION OF THEORY

---

Case studies investigate phenomena in their real-life context, potentially using data collected in a number of ways, both active (interviews, participant observation, direct observation) and passive (archival and physical evidence), and the theories resulting from them allow an in-depth understanding of why and how an instance happened as it did. When using apparently relevant extant theory to develop questions about the phenomenon under study, that extant theory can be built upon and

extended through the use of multiple case studies to induce relevant new constructs and propositions related to how it particularly applies in a variety of situations. As noted by Robert Yin, multiple cases are like multiple experiments, to which the previously developed theory can be compared and extended to account for the empirical results of the case study. The examination of the rich data collected in these varied theoretically significant settings exposes the additional constructs and relationships that must be included in the theory to reflect the actual complete case study data.

### Conceptual Overview and Discussion

There are several ways case studies can be used to assess the significance of theoretical additions to extant theory. These include using a comparative case method to tease out differences between the cases, thus highlighting important differences between them for further analysis (an ANOVA/MANOVA type of study). A case survey similarly examines potentially masses of cases to inspect the effects of particular factors on each of them, allowing for a quantitative assessment of patterns across a volume of case studies (a multiple regression type of study, notably Larsson and Finkelstein's study of acquisition success). When a research question is closely bounded within the context of an existing theory, using a set of theoretically relevant case studies to understand complex processes that occur in the context of this theory is appropriate.

### Application

The following paragraph is an example of an application of extension of theory. For researchers exploring questions of how organizations can maintain and improve performance even in times of dwindling external resources, there is nowhere else to look but at how effectively they use their internal resources. The most relevant theoretical base from which to examine such a question is that encompassed within the theory known as the resource-based view of the firm, which suggests that the basis for a competitive advantage of an organization lies primarily in the application of the bundle of valuable resources at the firm's disposal. In this context, the concept of dynamic *capabilities*, a foundational internal resource allowing an

organization to build ways to adapt to changing environments, is an appropriate starting point. Unfortunately, however, there is a gap in the literature addressing the microprocess questions of *how* actors make these internal capabilities work toward improving the organization's ability to perform. As such, it is necessary to study multiple cases of how these have worked in and across organizational settings to expose important procession dynamics: how and why certain processes unfold over time.

Two different studies of how managers at different levels in public sector healthcare organizations contribute to improved performance explicate the use of multiple case studies to extend existing theoretical models for how this might work. For example, Graeme Currie and Stephen Procter's study of organizational performance in the United Kingdom's National Health Service exemplifies work that successfully uses multiple case studies in a single industry setting to be able to generalize theoretically on the basis of the data collected from middle managers in four different hospital groups. This particular study extended previous theory on the role that middle managers play in creating and enacting strategies directed toward performance improvement. The findings of this work introduce a previously unrecognized set of contingency factors impacting the strategic role that middle managers are able to play in this effort, introducing the importance of role conflict and ambiguity-provoking behaviors that impacted outcomes.

Similarly, Amy Pablo, Trish Reay, James Dewald, and Ann Casebeer's study of a public sector health organization looked at *how* that organization used dynamic capabilities as a strategic approach to improve performance during a time of decreasing financial resources. In this study, they examined how different key players at multiple levels and sites in an organization followed a major strategic approach directed at using internal resources. Since the primary research questions of this study related to *how* public sector organizations attempted to use their internal resources to improve organizational performance, extension of the dynamic capabilities theoretical base to include more processual constructs is appropriate; this extension obviously requires the use of the rich qualitative data achievable with case studies. The findings of this study reflected an extension to the basic dynamic capabilities theoretical framework

by identifying a phase and role-based set of propositions for how this internally focused strategy actually works. From this work it was even suggested that the key players had to be able to move around within the boundaries of the previously defined theoretical framework, occupying different spaces covering the cognitive, social, and behavioral elements over time as circumstances dictated; thus both dimensional and temporal elements became apparent through the multiple case study approach to studying this phenomenon through the identified theoretic lens.

Based on the applications described above, we can see how well-received extant theories were expanded and enhanced when multiple case studies using them as a foundation were found to be incomplete in their explanation of the data actually captured from theoretically logical samples of cases.

### Critical Summary

Extension of theory using multiple case studies not only expands the value of a particular theoretical perspective, but also helps to define the boundary conditions of the original theory. The challenge is to assess whether there are unique attributes to the particular theoretical application or its setting that may limit generalizability of the extension. Further research using more fine-grained examinations of the potentially limiting attributes is warranted.

## EXTREME CASES

---

The extreme cases approach is employed when the purpose is to try to highlight the most unusual variation in the phenomena under investigation, rather than trying to tell something typical or average about the population in question. Extreme cases can be selected based on the maximum variation measured by different factors; however, opposite and outlier status can also be used as criteria.

### Conceptual Overview and Discussion

When starting a case study project, one of the most important decisions to be made is selecting a strategy for sampling the cases. As Bent Flyvbjerg has pointed out, the selection can be based on random sampling, as is done in more traditional quantitative studies. However, the very nature of the case study research, as an explorative mode of conducting research, more often leads to the use of information-oriented selection strategies instead of randomization. The information-oriented selection strategy is a deliberate way of selecting the cases for the study. It is based on the idea of trying to find paradigmatic cases, critical cases, maximum variation cases, or extreme or deviant cases with respect to the study population and the questions being posed to this group. When using the maximum variation strategy, cases that reflect both the highest and lowest status with respect to the variable(s) being measured will be presented to capture the extent of the diversity that has been observed in the study population.

Extreme cases may be selected during two different phases of case study research: (1) when determining the method of data collection and selecting the cases from a larger pool of possible cases available for study, and (2) after doing the preliminary analysis of a larger pool of cases and deciding to concentrate on a more in-depth analysis of one or more extreme or deviant cases, which typically leads to reporting these cases as a separate part of the study or as an independent substudy.

### Application

The main purpose of selecting extreme cases in the data gathering phase is to find a starting point for the study, and to determine the methods of measurement and data analysis. The researcher will select cases that demonstrate the most obvious differences from the majority of the sample, in terms of their available background data, that is relevant to the study questions. He or she will then inquire further, and in a very detailed way, about these participants in order to develop a holistic picture of these exceptional cases. A very common way of making decisions about which cases to select is to consider what previous data (e.g., test results) that have been acquired from the study population suggest about which cases will prove most informative. For example, in a study concerning student characteristics that are related to dropping out of high school, by Christine Christle, Kristine Jolivet, and C. Michael Nelson, the schools selected for closer examination were selected based on the lowest and highest rates of student attrition reported during previous phases of a larger study.

It is important to draw upon theoretical assumptions of which individual traits (e.g., gender, socioeconomic status) may influence variation in the research phenomena under question. In some studies, it is relevant to sample extreme cases from both males and females in a sample. Similarly, when comparing different countries, extreme cases may need to be selected from populations that experience the same kinds of economic circumstances (e.g., the same level of industrialization) in order to draw meaningful comparisons between them.

For organizing and presenting the study findings, it is often useful to apply the extreme cases approach to achieve a more in-depth understanding of the nature of the phenomenon under study. This is highly recommended in the event of having a very large number of cases (more than 20) in the study, and when it is not effective to present all the cases in a detailed fashion. By using extreme cases, the researcher will more effectively demonstrate the main points of the study, as well as explain the extreme outcomes, diverse solutions, and practices of case participants in a succinct fashion. For example, in a study by Markku Jahnukainen and Tero Järvinen, only two extreme cases of the life courses of 52 former high-risk

youth under investigation were presented to demonstrate the observed diversity in the trajectories of these at-risk adolescents.

At times, a remarkable set of extreme cases cannot even be displayed in the main report of a study, as such data may distract the reader from the central findings of an investigation. In such cases, it is a good idea to publish a technical report, or else place these case descriptions in the appendices of the main report. To present the extreme cases optimally, detailed data should be collected to build profiles on all of the cases. The research data can be qualitative or quantitative. Both kinds of data can often be used, with the extreme cases usually presented in studies that employ mixed methods. On the whole, the cases will be discussed first in a general way. The differences and similarities between cases as well as the controversies that emerge from them will be discussed in a more specific fashion later in the report. The report will also be presented in tables or figures that reflect key findings discussed in the text. One typical way of presenting the cases is in a story format. This is a good solution, in particular if the data are derived from a longitudinal design and it is possible to organize the information in chronological order. Even though, in most situations, only one or two extreme cases are selected in a study, at times several sets of “extreme cases” can be used, depending upon how many independent variables or measures the study contains.

### Critical Summary

The extreme cases approach is a useful tool for both organizing one’s data collection and presenting the findings from a larger set of case studies. It is a powerful way to illustrate the diversity in the phenomenon being studied and to demonstrate the theoretical implications of the case study research. However, the challenge in these kinds of case studies is to communicate the results in such a way that the reader can follow the researcher’s decision-making process in both deciding to employ the extreme cases approach and in selecting the specific cases to be presented.

## FACTOR ANALYSIS

---

A measure (e.g., a test, a questionnaire or a scale) is useful if it is reliable and valid. A measure is valid if it measures what it purports to measure. Validity can be assessed in several ways depending on the measure and its use. Factorial validity is a form of construct validity that is established through a factor analysis. Factor analysis is a term that represents a large number of different mathematical procedures for analyzing the interrelationships among a set of variables and for explaining these interrelationships in terms of a reduced number of variables, called factors. A factor is a hypothetical variable that influences scores on one or more observed variables. Below is a short introduction to some popular types of validity used by researchers and a specific introduction to factor analysis.

### Conceptual Overview and Discussion

#### *Types of Validity and Validation*

*Content validation* is employed when it seems likely that test users will want to draw references from observed test scores to performances on a larger domain of tasks similar to items on the test. Typically, it involves asking expert judges to examine test items and judge the extent to which these items sample a specified performance domain. There are two types of content validity: face validity and logical validity. A test has face validity if an examination of the items leads to the

conclusion that the items are measuring what they are supposed to be measuring. Logical or sampling validity is based on a careful comparison of the items to the definition of the domain being measured.

*Criterion-related validation* is a study of the relationship between test scores and a practical performance criterion that is measurable. The criterion is the thing of interest or the outcome researchers are concerned about. When a test score,  $X$ , can be related to a criterion score,  $Y$ , criterion-related validity can be determined. The validity coefficient,  $\Delta_{XY}$  can be based on a predictive or a concurrent study. A predictive-validity coefficient is obtained by giving the test to all relevant people, waiting a period of time, collecting criterion scores, and calculating the validity coefficient. When a test is used to predict future behavior, predictive validity can be calculated.

*Construct validation* is appropriate whenever the test user wants to draw inferences from test scores to a behavior domain that cannot be adequately represented by a single criterion. A test's construct validity is the degree to which it measures the behavior domain or traits that it was designed to measure. More specifically, construct validity can be understood as the extent to which the behavior domain or the constructs of theoretical interest have been successfully operationalized. For example, a researcher may be interested in determining clients' satisfaction with healthcare services. Since "satisfaction with healthcare services" is a construct that cannot be adequately represented by a criterion or defined by a universe

of content, the researcher chooses to develop a questionnaire of 20 items in order to tap the construct “satisfaction” and proceeds to collect the data. The question is how does the researcher know that what he or she is measuring through the questionnaire is actually and purely clients’ satisfaction with healthcare services and not something else or a mixture with other constructs such as clients’ degree of confidence in the medical profession? In this case, a construct validation is appropriate.

Establishing construct validity is an ongoing process that involves the verification of predictions made about the test scores. Procedures for construct validation may include correlations between test scores and designated criterion variables, differentiation between groups, factor analysis, multitrait–multimethod matrix analysis, or analysis of variance components within the framework of generalizability theory. The following contains introductions and explanations of one of the procedures for determining construct validity: the factor analysis.

*Factorial validity* is a form of construct validity that is established through a factor analysis. *Factor analysis* is a term that represents a large number of different mathematical procedures for analyzing the interrelationships among a set of variables and for explaining these interrelationships in terms of a reduced number of variables, called factors. A factor is a hypothetical variable that influences scores on one or more observed variables. For example, let’s look at the following hypothetical correlation matrix:

		TEST		
		1	2	3
Test	1	1.00	.99	.94
	2	.99	1.00	.97
	3	.94	.97	1.00

Although there are three test scores being correlated, it is quite obvious that only one dimension/factor is being measured, because of the high correlations among the test scores: This is based on the assumption that tests measuring the same trait should correlate highly, converging on the

trait. Instead of requiring three scores for each person, one score alone could be sufficient.

The preceding example involves an “educated guess” method of factor analysis. This is possible if the correlation matrix is small and simple. But most of the correlation matrices researchers deal with are more complex, and the “educated guess” method of factor analysis is either difficult or unreliable (or both). However, the logic underlying the above simple example in terms of determining the number of factors remains the same for complex cases. This logic is helpful in determining the construct validity of a test, with the help of the SPSS factor procedure. Briefly: the correlation matrix is approximated by the factors (usually fewer than the number of variables). The researcher hopes this approximation is a good one, that is, the original correlation matrix is close to the one produced by fewer factors (in other words, has small residual when the original correlation is compared to the factor analysis produced correlation). There are two general types of factor analysis, *confirmatory* factor analysis (CFA) that is used when the researcher knows the number of factors and can specify or constrain the loadings of variables, and *exploratory* factor analysis (EFA), where all loadings are free to vary. This entry discusses only exploratory factor analysis.

To go back to the example on “satisfaction with healthcare services” cited earlier, it is not difficult to envisage that if the 20-item questionnaire is really a valid measure of the construct “satisfaction with healthcare services,” a factor analysis on the scores of the 20-item questionnaire should result in one factor that can explain most of the variance in these 20 items. But if the 20-item questionnaire is instead measuring two different behavior domains (e.g., “Satisfaction with healthcare services” and “Confidence in the medical profession”), factor analysis on the scores of the 20-item questionnaire should result in two factors, with items measuring “satisfaction” having high factor loadings on one factor and items measuring “confidence” loading highly on the remaining factor. The meaning of factor loadings is discussed in greater detail in a later section. In the meantime, just imagine that a factor loading is a number that is very much like a correlation coefficient in size and meaning. When a factor analysis is conducted

on a correlation matrix, tests that are influenced by certain factors are said to have high factor loadings or to load highly on those factors.

### Application

The following sections illustrate the use of factor analysis on a small study involving a group of adolescents who have difficulty controlling their aggressive behaviors. The data are a subset of a real case study conducted on a sample of individuals who were referred to professionals for counseling. The therapists developed the following questionnaire to help them gauge the aggressiveness of the adolescents involved. The data are provided as well as the SPSS output of the factor analysis procedure.

The following illustrative example contains 6 items extracted from a scale designed to measure adolescents' attitude toward the use of physical, aggressive behaviors in their daily life. Each item in the scale refers to a situation where aggressive physical behavior is or is not used. Adolescents are asked whether they agree or disagree with each and every item on the scale. Adolescents' responses to the items are converted to scores of either 1 or 0, where 0 represents disapproval of the use of aggressive physical behaviors. Below are the contents of the 6 items as well as the scores of 14 adolescents on these 6 items:

<i>Item No.</i>	<i>Content</i>
1	When there are conflicts, people won't listen to you unless you get physically aggressive.
2	It is hard for me not to act aggressively if I am angry with someone.
3	Physical aggression does not help to solve problems, it only makes situations worse.
4	There is nothing wrong with a husband hitting his wife if she has an affair.
5	Physical aggression is often needed to keep things under control.
6	When someone makes me mad, I don't have to use physical aggression. I can think of other ways to express my anger.

The following is the data obtained from 14 adolescents:

	<i>Item</i>					
<i>Person</i>	1	2	3	4	5	6
1	0	0	0	0	0	0
2	0	0	0	0	1	0
3	1	0	1	1	1	0
4	1	1	1	1	1	1
5	1	1	1	1	1	1
6	0	0	1	0	0	0
7	0	0	1	1	1	0
8	1	1	1	1	1	0
9	0	0	0	1	0	0
10	0	1	0	1	0	1
11	1	1	1	0	1	1
12	0	0	1	1	1	1
13	0	0	0	0	0	0
14	0	0	0	0	0	0

Factorial validity of the above scale can be assessed using factor analysis. The primary purpose of conducting factor analysis on the scores of the 6-item scale is to find support for the assumption that this 6-item scale is measuring a single construct: "adolescents' attitude toward the use of physical, aggressive behavior in daily life." If this assumption is supported, a factor analysis on this set of data should point to a one-factor solution.

There are two major phases in the factor analysis, namely, the factor extraction phase and the rotation phase. Several different strategies are available for each of the two phases in the SPSS factor procedure. The following methods can be chosen to carry out the extraction phase in the SPSS factor procedure: principal components analysis (the default); principal axis factoring; maximum likelihood; alpha factoring; image factoring; unweighted least squares; and generalized least squares. In the rotation phase, the following methods are available in the SPSS factor procedure: varimax rotation (the default); equamax rotation; quartimax rotation; direct oblimin rotation; and no rotation.

For the purpose of the present analysis, the principal components analysis (pc) and the varimax rotation methods will be used, since these two methods are the defaults.

*Conducting Factor Analysis Using SPSS OUTPUT*  
SPSS Outputs and Discussions

The initial part of the output contains a correlating matrix showing the correlation coefficients

among the items. Please note that the 1-tailed Significance of the Correlation Matrix will also be given if the SPSS correlation procedure is used. However, the SPSS program used here will not give the 1-tailed Significance.

**Table 1** Correlation matrix

		ITEM1	ITEM2	ITEM3	ITEM4	ITEM5	ITEM6
Correlation	ITEM1	1.000	.689	.645	.344	.645	.378
	ITEM2	.689	1.000	.344	.344	.344	.689
	ITEM3	.645	.344	1.000	.417	.708	.344
	ITEM4	.344	.344	.417	1.000	.417	.344
	ITEM5	.645	.344	.708	.417	1.000	.344

**Table 2** Communalities

	Initial	Extraction
ITEM1	1.000	.725
ITEM2	1.000	.878
ITEM3	1.000	.805
ITEM4	1.000	.382
ITEM5	1.000	.805
ITEM6	1.000	.790

Note: Extraction method: Principal component analysis.

In the above correlation matrix the largest correlation coefficient occurs between item 3 and item 5 (i.e.,  $r = .70833$ ). The second largest correlation coefficient is .68889, which occurs between items 1 and 2 as well as between items 2 and 6. The smallest correlation coefficient is .34427, and all of the following 7 pairs of items have this correlation coefficient: items 2 and 3; items 2 and 5; items 4 and 1; items 4 and 2; items 4 and 6; items 6 and 3; and items 6 and 5. The next smallest correlation coefficient is .37778, which occurs between items 1 and 6. Based on the above correlation matrix and using the crude method of “educated guess” factor analysis, it can be suggested that there are possibly two factors. Item 2 and item 6 seem to load on one factor and items 1, 3, and 5 on the other. However, item 2 is also highly correlated with item 1 ( $r = .68889$ ). Besides, item 4 itself can possibly load on another factor (because it is not

highly correlated with any one of the other factors), but since the correlation coefficients between item 4 and each of items 3 and 5 amount to .41667, which cannot be regarded as particularly low, it can be postulated that item 4 may load on the same factor as items 3 and 5.

However, the above suggestions are based on very crude analyses and are not very conclusive. More sophisticated analyses have to be performed by the SPSS factor procedure. The following section of the output consists of the matrices and statistics obtained from using the method of the “principal components analysis” in the extraction phase of the factor procedure (see Tables 2–5).

**Extraction 1 for Analysis 1,  
Principal-Components Analysis (PC)**

What principal components analysis basically does is transform a set of correlated variables (in this case, each item is a variable) to a set of uncorrelated variables (or principal components). In the context of the present phase of factor analysis, these uncorrelated variables are the factors. In principal components analysis, linear combinations of the observed variables are formed. The first principal component (or factor in this context) is the combination that accounts for the largest amount of variance in the sample. The second principal component accounts for the next largest amount of variance and is uncorrelated with the first. Successive components explain progressively smaller portions of the total sample variance, and all are uncorrelated with each other.

**Figure 1** Scree plot

**Table 3** Total variance explained

<i>Component</i>	<i>Initial Eigenvalues</i>			<i>Extraction Sums of Squared Loadings</i>			<i>Rotation Sums of Squared Loadings</i>		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	3.361	56.025	56.025	3.361	56.025	56.025	2.474	41.239	41.239
2	1.024	17.071	73.096	1.024	17.071	73.096	1.911	31.857	73.096
3	.734	12.227	85.323						
4	.471	7.846	93.169						
5	.292	4.861	98.030						
6	.118	1.970	100.000						

Note: Extraction method: Principal component analysis.

The matrix under the heading “Initial Statistics” contains the solution of the principal components analysis when all possible factors are included in the solution. It is possible to compute as many principal components as there are variables; in this example, there can be as many as 6 principal components or factors. These Initial Statistics basically tell us the amount of variance explained by each factor as well as the percentage of the total variance in the sample attributed to each factor. To make more sense out of these statistics, we need to understand how the total variance of the sample is worked out.

The total variance is the sum of the variance of each variable (or item, in this case). In the principal components analysis, all variables and factors are expressed in standardized form, with a mean of 0 and a standard deviation of 1. Since there are 6 items in this example and each is standardized to have a variance of 1, the total variance is 6 in this example.

The *eigenvalue* is the amount of variance explained by each factor. The first column of “Initial Statistics” contains 6 eigenvalues, one for each of the possible 6 factors, respectively. The

**Table 4** Component matrix

	Component	
	1	2
ITEM1	.848	-7.500E-02
ITEM2	.762	.545
ITEM3	.785	-.435
ITEM4	.610	-9.618E-02
ITEM5	.785	-.435
ITEM6	.676	.577

Note: Extraction method: Principal component analysis, two components extracted.

sum of these 6 eigenvalues is equal to the total variance of the sample: that is, 6. The 6 eigenvalues are arranged in descending order, with the largest at the top of the column and the lowest at the bottom. Among the 6 factors, factor 1 accounts for the largest amount of variance in the sample, while factor 6 contributes the smallest amount. For factor 1, the corresponding eigenvalue is 3.36147, which means that out of a total variance of 6, 3.36147 can be attributed to factor 1. It follows naturally that the percentage of variance accounted for by factor 1 is 56.0%, which is obtained from the following computation: 3.36147 divided by 6 times 100%. For factor 6, the eigenvalue and the percentage of variance accounted for is 0.11817% and 2.0%, respectively.

A brief introduction of the factor analysis model is necessary in order to understand the meaning of *communality*. Under the factor analysis model, the  $z$ -scores on variable  $i$  are seen as combinations of basically two components, namely, summation of scores on  $m$  common factors, and scores on the factor unique to variable  $i$ . The factor analysis model is best illustrated by the following equation:

$$z_i = \sum_{k=1}^m a_{ik} f_k + u_i \quad (1)$$

where  $z_i$  represents  $z$ -scores on variable  $i$ ,  $a_{ik}$  represents the loadings of variable  $i$  on factor  $k$ ,  $f_k$  represents scores on common factor  $k$ , and  $u_i$  represents scores on the factor unique to variable  $i$ . A common factor is a factor with which two or more variables are correlated and hence contributes to the observed correlations between these

variables; it is actually the same as the “factor” that we have consistently been referring to in the above discussion. A unique factor is correlated with only one variable (a unique factor, therefore, should be uncorrelated with any of the common factors and should also not be correlated with any unique factors for other remaining variable) and hence does not account for correlations between variables.

An important question in a factor analysis is what portion of a variable’s variance is associated with variance on the common factors (i.e., the proportion of the variable’s variance that is explained by the common factors). This amount is called *communality* or the common variance and is calculated by

$$h^2_i = \sum_{k=1}^m a_{ik}^2 \quad (2)$$

where  $h^2_i$  is the communality of variable  $i$  for uncorrelated factors. The proportion of a variable’s variance associated with variance on its unique factor is called the *uniqueness* or the unique variance and is calculated by

$$u^2_i = 1 - h^2_i \quad (3)$$

where  $u^2_i$  is the uniqueness of variable  $i$ .

Theoretically,  $u^2_i = s^2_i + e^2_i$ , where  $s^2_i$  is the specific variance of a variable (i.e., the portion of a variable’s true score unrelated to true score variance on any of the other variables included in the factor analysis), and  $e^2_i$  is the error variance. Therefore, the total variance (which has been standardized as 1) can be expressed by

$$h^2_i + s^2_i + e^2_i = 1. \quad (4)$$

The communality is usually a number less than 1. In the “Initial Statistics” matrix, all the communalities are 1. This is because all factors are included in this solution. When all factors are included in the solution, all of the variance of each variable is accounted for, and there is no need for a unique factor in the model. The proportion of variance accounted for by the common factors (a total of 6 factors in this case), or the communality of a variable, is therefore 1 for all the variables.

### Determination of the Number of Factors in the Model

However, if all the possible factors are included in the solution, there is nothing gained since there are as many common factors (or simply factors or principal components) as variables. A common criterion used to determine the number of factors to use in the model is that only factors that account for variances greater than 1 (i.e., the eigenvalue is greater than 1) should be included. This is in fact the default criterion in the SPSS factor procedure. The rationale behind this criterion is that factors with a variance less than 1 are no better than a single variable, since each variable has a variance of 1. In the present example, the computer procedure suggests that a model with two factors may be adequate to represent the data (as shown in the "Factor Matrix" and the "Final Statistics"). It can be seen from the Final Statistics that each of these two factors has an eigenvalue greater than 1 (i.e., 3.36147 and 1.02428, respectively) and that together they account for more than 73% of the total variance of the sample.

Another method that can be used to decide the number of factors in the model is to inspect the scree plot, a plot produced between the Initial Statistics and the Factor Matrix in the output. Typically, the plot should show a distinct break between the steep slope of the large factors and the gradual trailing off of the rest of the factors. The gradual trailing off is called the scree, and experimental evidence indicates that the scree begins at the  $k$ th factor, where  $k$  is the true number of factors. The scree plot in the present output basically supports a 2-factor solution, because the scree begins at the second factor. (There may be some disagreement on whether factor 2 should be included in the model because its eigenvalue just barely exceeds 1 and it is also likely that "it is already on the scree" in the scree plot; however, since this factor explains more than 17% of the total variance in the sample, which when added to the first factor gives more than 70% of the variance, it would not be unreasonable to include it in the model.)

### Factor Loadings and Community

The figures produced in the Factor Matrix are the factor loadings. To put it simply, the factor loading of a variable on a factor represents how much weight is assigned to the factor. When the factors are orthogonal (i.e., when they are

uncorrelated with each other), the factor loadings are also correlations between the factors and the variables. Since the principal components analysis is used to extract factors in this example, the resulting two estimated factors must be orthogonal. Hence, from inspecting the figures in the Factor Matrix, we can say, for example, that the correlation between item 2 and factor 1 is .7624 and that the correlation between item 6 and factor 2 is .57746, and so on.

Since the two resulting factors are orthogonal, the communality shown in the Final Statistics can be calculated from the appropriate factor loadings in the Factor Matrix using equation 2.

For example, the communality of item 1 can be obtained from adding the squares of its factor loadings on factor 1 and factor 2, that is,  $.72545 = (.84843)^2 + (-.07500)^2$ . This communality of item 1 means that 72.545% of the variance of item 1 is explained by the two common factors.

### Relationship Between Factor Loadings and Variable Intercorrelations

One of the basic assumptions of factor analysis is that the observed correlation between variables is due to the sharing of common factors. Therefore, the correlation between a pair of variables has a very important relationship to the loadings of the two variables on the factors. When the factors are orthogonal, the general equation relating the variable intercorrelations to factor loadings is

$$p_{ij} = \sum_{k=1}^m a_{ik} a_{jk} \quad (5)$$

where  $p_{ij}$  is the correlation between scores on variables  $i$  and  $j$  (in this example, it is the correlation between items  $i$  and  $j$ ),  $a_{ik}$  and  $a_{jk}$  are respectively the factor loadings of variable  $i$  and  $j$  on factor  $k$ , and  $m$  is the number of factors. When there are two factors, as in this example, the relationship is:

$$p_{ij} = a_{i1} a_{j1} + a_{i2} a_{j2}$$

As an illustration, the factor loadings of item 4 and item 6 on factor 1 and factor 2 are used to compute the correlations between item 4 and item 6:  $p_{46}$  is therefore equal to the sum of  $a_{41} a_{61}$  and  $a_{42} a_{62}$ , which is .35690 (this value is obtained from  $(.61204)(.67586) + (-.09618)(.57746)$ ). When

compared with the observed correlation coefficient between items 4 and 6 (i.e.,  $r_{46} = .34427$ ) in the correlation matrix given in the output, there is a difference of .01263. This difference is called a residual. For this set of data and analysis, this residual is already the smallest. The biggest residual occurs between items 1 and 4, which is equal to .18069 (i.e., the difference between the correlation coefficient of .52496 computed from equation 5 and the observed correlation coefficient of .34427 from the correlation matrix in the output).

There is a major explanation for the occurrence of residuals (i.e., the differences between correlations among pairs of items calculated from the equation and their corresponding observed correlations): For correlation calculated for a sample, equation 5 will be satisfied exactly only for  $N - 1$  factors, where  $N$  is the number of variables. It follows that, in this example, equation 5 can be satisfied exactly only in a 5-factor solution. Since the present calculations are based on a 2-factor solution that explains about 73% of the total variance in the sample, the discrepancies between the observed and computed correlations are expected to occur.

Factor loadings shown in the Factor Matrix are usually called initial or unrotated loadings because they are obtained by using a method that permits convenient calculation of the loadings. Typically, researchers do not attempt to interpret these unrotated loadings of the Factor Matrix. This is because very often the variables and factors in this matrix do not appear correlated in any interpretable pattern and it is usually difficult to identify meaningful factors based on this matrix. The Factor Matrix of unrotated loadings in this example is not easy to interpret either. All items have very high loadings on factor 1, and if we follow the conventional rule that loadings less than .30 are considered unimportant, 4 items (i.e., items 2, 3, 5 and 6) also have very high loadings on factor 2. Even if we raise the critical level to .50, we still have item 2 and item 6 loading highly on factor 2.

The rotation phase of factor analysis attempts to transform the initial matrix into one that is easier to interpret. (The process of transforming the initial matrix into one that is easier to interpret is complicated and will not be explained here. Basically, all methods of rotation will result in a set of transformation equations used to transform the initial factor loadings so that they approximate

simple structure). With reference to the present example, when the items have been plotted on a two-dimensional plot using the initial factor loadings as coordinates, with different factors represented by different axes (i.e., factor 1 on the x-axis and factor 2 on the y-axis), the rotation phase of factor analysis basically involves finding two new axes, one that passes closer to the first cluster and a second that passes closer to the second cluster. The purpose of rotation is to achieve a simple structure. Essentially, the simple structure criteria imply that each variable should have large loadings on as few of the factors as possible (preferably one) and low or zero loadings on the remaining factors. A Factor Matrix that satisfies the simple structure criteria permits the factors to be differentiated from each other, or to put this in another way, such matrix would allow easier identification of sets of closely related variables.

There are two classes of rotations: orthogonal and oblique. Orthogonal rotations result in uncorrelated factors, whereas oblique rotations result in correlated factors. Both classes of rotations involve finding new axes in a factor loadings plot so that the axes pass closer to clusters of variables. But the new axes must be perpendicular for orthogonal rotations, whereas the new axes of an oblique solution are not perpendicular. Rotation does not affect the goodness of fit of a factor solution; that is, although the Factor Matrix changes, the communalities and the percentage of total variance explained do not change. Factor loadings resulting from orthogonal solutions satisfy both equations 2 and 5, but if these two equations are applied to factor loadings obtained from oblique solutions, they will be satisfied only when additional terms that take into consideration the correlations among the factors are added to the equations.

In this example, the varimax rotation method is used. Varimax rotation belongs to the class of orthogonal rotations, thus it will result in uncorrelated factors. The outputs reproduced below are the results after the varimax method has been applied to the initial Factor Matrix. It contains a rotated factor matrix, a factor transformation matrix, and a factor loadings plot. Since the factor transformation matrix is not particularly relevant to the present discussion, discussions are focused mainly on the rotated Factor Matrix and the factor loadings plot.

**Table 5** Rotated component matrix

	<i>Component</i>	
	1	2
ITEM1	.714	.464
ITEM2	.265	.899
ITEM3	.886	.140
ITEM4	.540	.300
ITEM5	.886	.140
ITEM6	.177	.871

Notes: Extraction method: Principal component analysis. Rotation method: Varimax with Kaiser normalization. Rotation converged in 3 iterations.

#### Varimax Rotation 1 for Extraction 1 in Analysis 2—Kaiser Normalization

The Rotated Factor Matrix appears to be a little easier to interpret than the previous Factor Matrix. With the exception of item 1, all items have high factor loadings on only one factor. If .5 is employed as the critical value of factor loadings (i.e., factor loadings smaller than .5 are considered unimportant), we can draw the following conclusions from the Rotated Factor Matrix:

A two-factor solution is adequate to represent the data  
Items 1, 3, 4, and 5 load primarily on factor 1, while  
items 2 and 6 load primarily on factor 2

The above conclusions seem to match the results of the “educated guess” factor analysis described at the beginning of this entry. However, these results do not seem to support the original assumption; that is, this 6-item scale measures a single construct: adolescents’ attitude toward the use physical, aggressive behaviors in their daily life.

Another convenient means of examining the success of an orthogonal rotation is to plot the variables using the factor loadings as coordinates on a factor loadings plot. The plotted numbers represent the numbers of the variables (or items in this case), for example, 2 represents item 2. The coordinates of

each plotted number correspond to the factor loadings in the Rotated Factor Matrix, with factor 1 represented by the x-axis and factor 2 by the y-axis. The coordinates are also listed under the plot.

If a rotation has achieved a simple structure, clusters of variables should occur near the ends of the axes and at their intersection. Variables at the ends of the axis are those that have high loadings on only that factor. Variables near the origin of the plot have small loadings on both factors. Variables that are not near the axes are explained by both factors. If a simple structure has been achieved, there should be few, if any, variables with large loadings on more than one factor.

There are 5 plotted numbers in the reproduced factor loadings plot instead of 6. This is because item 3 and item 5 have the same coordinates (i.e., same loadings on factor 1 and same loadings on factor 2), and the computer prints only one of them, that is, 5, on the plot. Basically, most of the plotted numbers are located near the ends of the axes. Item 1 appears to be a little away from the axes because it also has comparatively high loading on factor 2. Nevertheless, the plot indicates that the rotation has achieved a relatively simple structure, with the majority of the plotted numbers located near the ends of the axes.

**Figure 2** Component plot in rotated space

### *What Conclusions Can Be Drawn From the Factor Analysis on This Set of Data on the 6-Item Scale?*

Instead of a predicted 1-factor solution, a 2-factor solution is reached by this factor analysis. The original assumption that the 6-item scale is measuring one construct is not supported by the analysis. A closer look at the 6 items may suggest why a 2-factor solution is reached. One of the possible explanations is that items 2 and 6 appear to be related to how the respondents would actually behave in conflict situations, while items 3, 4, and 5 (and to a great extent item 1 also) refer to the use of physical, aggressive behaviors in general situations when respondents' immediate and actual responses and behaviors are not directly involved or asked. If we examine item 1, which also has moderately high loading on the factor on which items 2 and 6 primarily load (i.e., factor 2), we can find some support for the above explanation. While item 1 may be primarily designed to refer to some general situation when physical, aggressive behaviors were used, the portion of item 1 that reads "people won't listen to you unless you get physically aggressive" may unexpectedly invite the respondents to think about how they would actually behave when they are probed with this item. Based on the above factor analysis results and explanations, we can suggest that the 6-item scale may be measuring two constructs or two dimensions of the same construct. Factor 1 may be measuring adolescents' general attitude toward use of physical, aggressive behaviors in daily life, and factor 2 may in fact be measuring adolescents' predisposition to act aggressively when provoked. Nevertheless, the above explanation may be only one of the many possible explanations for why a 2-factor solution appears to be more appropriate.

Reliability analysis on the same set of data suggests that the scale has a very high inter-item reliability coefficient (Cronbach's  $\alpha = .8396$ ). However, results of the present analysis do not offer support to the claim that this scale/questionnaire is a homogeneous instrument. While reliability analysis suggests that item 4 should be the first to go if some items are to be deleted from the scale, this factor analysis also points to the need to look more closely into item 1. In any event, the scale developer has to revise the scale if he or she hopes that only one construct will be measured by

the scale. Other methods for construct validation should also be employed to improve the construct validity of this scale.

### **Critical Summary**

The correlation matrix of a questionnaire or test is approximated by the factors (usually fewer than the number of variables) when a researcher conducts a factor analysis. The researcher hopes this approximation is a good one; that is, the original correlation matrix is close to the one produced by fewer factors. In other words, there is a small difference between the two matrices or, in statistical terms, there is a small residual when the original correlation matrix is compared to the factor analysis produced correlation matrix. There are two general types of factor analysis, confirmatory factor analysis (CFA) that is used when the researcher knows the number of factors and can specify or constrain the loadings of variables, and exploratory factor analysis (EFA), where all loadings are free to vary. This entry discussed only exploratory factor analysis.

Two reminders about effective use of factor analysis:

1. Rule of thumb for the minimum sample size in factor analysis: 100 subjects or 10 times the number of variables (whichever is larger) (thus, the sample size of this example is too small!)
2. Factors are hypothetical constructs and do not have meanings by themselves; meaningful interpretation of the resulting factors must have to be based on sound theoretical frameworks and unbiased and careful analyses

## FALSIFICATION

---

It can never be proved, logically, that a theory presents an accurate or “true” view of what it explains, whereas it is always possible—again, logically—to prove a theory is false by identifying data contrary to that which the theory explains, or by showing that it predicts something contrary to what is observed. The influential philosopher of science Karl Popper argued that science should actively attempt to find counterexamples—evidence that would refute its theories. Refutation of a theory indicates it is false, and so the program advocated by Popper is known as falsificationism. Falsification is important in the social sciences, and particularly in case study, because of the importance accorded to an individual case. Frequently a case is undertaken that will show that a widely held theory is incorrect, and such a case will result in some limitation or constraint on the use and application of the theory in question.

### Conceptual Overview and Discussion

A (scientific) theory is usually developed inductively. Observation is made, data collected, and a generalized theory that explains the data is created. Since the explanation covers only observations already made or data already gathered, it is impossible to substantiate the claim that the theory is universally true. A theory may be shown to be wrong in one of two ways. First, it is possible that some relevant observation or data will be found that is not explained by the theory or that contradicts it. Second, theories ultimately depend on assumptions. Predictions are logical entailments of the basic assumptions. If the predictions are found to be false, then the assumptions must also be false. It is possible that any theory may be false, and so all theories are falsifiable.

One peculiar aspect of falsification is that if a theory withstands attempts to falsify it, it is deemed to be somehow strengthened. Claims concerning its universality are considered less likely to be wrong than they were, and untested predictions made by the theory are accepted more readily. We have more confidence that the theory is “true.” It is not easy to explain why this is so. If we lack evidence to disprove a theory at a particular time, and we still lack evidence to disprove the theory at some later time, the situation has not changed: We lack evidence to disprove the theory. One approach to this situation is to claim that as additional data are gathered, knowledge is increased, and thus every unsuccessful challenge increases confidence in the theory. But again, it is hard to say precisely why a supposedly universal theory is stronger because it explains more data.

Popper argued that one goal of science should be to actively attempt to find evidence that would falsify a theory or its predictions. In his view, science should make, and attempt to refute, “risky” predictions by constructing “critical experiments” that would, if successful, conclusively demonstrate the falsity of the theory. If the theory robustly resists such attempts to falsify it, our confidence in the theory is justifiably increased.

Popper may be correct: This is what science *ought* to do if it intends to establish the truth of its theories, but this does not seem to be what science actually does. The equally influential philosopher of science Thomas Kuhn argued that when evidence that might falsify a theory is found, the usual practice of science is either to discount the disconfirmatory evidence, or to amend the theory in an ad hoc way to accommodate the falsificatory data. He claimed that by using theories to solve problems, the actual practice of science is confirmatory.

At their inception, theories often assume the existence of unobserved objects, such as atoms or genes. These entities may later be observed, or they may remain “theoretical” objects. That such entities demonstrably exist, or that they cannot exist, is taken as very good cause to accept or reject the theory. However, since the existence of such objects is usually fundamental to the theory in question, science again tends to seek confirmatory rather than falsificatory evidence.

For example, CERN’s Large Hadron Collider (LHC) has cost up to 10 billion dollars to construct. It is to be used to provide evidence of the

existence of a particle known as the Higgs boson. The observation of such evidence, despite the circularity of basing the LHC experiment on the assumed correctness of the theory it is intended to support, will be taken to show the theory is correct; the non-observation will tell us absolutely nothing: Perhaps the Higgs boson was on vacation. It is clear that the LHC was not constructed in order to falsify theory, and therefore it can be argued that it is not, despite its cost, a critical experiment.

Popper was primarily concerned with the foundations, nature, and growth of scientific knowledge. But the core of falsification—that we can have increased confidence in a theory that successfully withstands attempts to falsify it—is an important part of the social sciences, and particularly in case study.

In case study, challenges to a theory may be presented as arguments. A case is not an experiment in which there is only one variable; there are often many factors that may influence an outcome. These influences may not be directly causal, and the researcher may argue that particular factors are (not) influential. Since the theory, or its relevance in a given situation, is supported by some argument, there is a judgment involved in its acceptance, and in this situation an unsuccessful attempt to falsify a theory will indeed strengthen that theory because an inductive argument that withstands challenges is more acceptable than one that doesn't.

### Application

Ted K. Bradshaw's study of the closure of an Air Force base in California, which also provides an example of a contrastive explanation, shows how a theory can be falsified. At the time of the study, it was widely accepted that the closure of such a base would have a catastrophic effect on the local community in terms of economic downturn and concomitant social upheaval. This received wisdom is the basis for political arguments intended to get money from the federal government (billions of dollars!) to support communities supposedly adversely affected by base closures. In the study, Bradshaw claims there is little empirical evidence to support the received wisdom. However, received wisdom has the status of a theory. As a theory it makes predictions that a military base's closing will have a catastrophic effect on the community in which the base is located. In this case, specific

predictions were of a 7% increase in unemployment, the loss of 3,694 jobs, a population loss of 18,000 people, and a loss of \$105 million in retail sales.

What the research found was that none of these predictions was satisfied. Unemployment attributable to the base closure raised the rate by 2%; there was no change in the annual employment patterns after the base closed compared with years before the base closed; the population count grew slightly; and retail sales grew (although a little more slowly than they might have grown had the base not closed).

Received wisdom was the basis for fairly specific predictions (in four areas) that were confounded by the data. Logically, one item of data is enough to refute a theory, but because the argument for received wisdom and the argument against it are both largely inductive, the combination of opposing evidentiary data provides strong reason to support the view that in this case received wisdom was false. In the spirit of Popper, we should have no more to do with it. However, there is perhaps well-founded reluctance to dismiss the theory holus-bolus. First, it provides the basis for an (often successful) argument to obtain federal government support for communities that experience military base closures. Second, not all military base closures will necessarily have the same effects. A case is unique, and we are limited in what generalizations may legitimately be inferred from it. However, this case should at least inform any predictions of the effects that similar closures might have on other communities. Third, received wisdom is brought to bear on broadly similar situations: What will happen when a major manufacturing plant closes in a community? What will happen when a popular tourist destination loses its attractiveness for some reason?

### Critical Summary

Falsification provides an incontrovertible means of establishing that a theory is incorrect, but it is not often used in science. It is more valuable in social science, particularly in case studies, because a particular instance that shows a theory to be false or inadequate can inform as to how we may or may not use the theory in other situations.

## FAMILIES

---

Families can be defined in universal, functional, structural, and inclusive ways. The predominant definition used by current family researchers is an *inclusive* one, which recognizes the many forms that families take and the varying roles carried out within families. From this standpoint, societal definitions are less important than individuals' perceived meaning, and families are viewed as private, voluntary groups rather than social institutions.

### Conceptual Overview and Discussion

Families are ideal research contexts in which to conduct case studies. This entry draws from family systems theory to identify characteristics that make families appropriate "cases" for case study research. Although case studies can be informed by many epistemological paradigms, this entry focuses on qualitative case studies informed by interpretive, heuristic, or critical paradigms.

#### *Families as Systems or Cases*

A number of researchers have noted that case study research involves a decision of *what* to study rather than *how* to study something. Case study research typically focuses on a single case, and as a "bounded system," there are elements of a case located inside it and other elements clearly located outside the system's boundaries. *Family systems theory* recognizes a family as a single case occurring within a larger environment, and a number of this theory's assumptions are relevant to case study research.

Case researchers draw on many features of a case to understand it, with one central focus on how a

case functions. From a family systems perspective, the assumption that "the whole is greater than the sum of the parts" is highly relevant to case study research. Family systems consist of more than just the simple addition of each family member; they include characteristics such as various behaviors and implicit or explicit ideologies that emerge out of the interaction between group members. Thus, family functioning can be understood only by viewing the whole system rather than parts of it. Case studies provide the means to understand the multifaceted inner workings of families by including all system elements, including various subsystems such as parents or sibling dyads, in an analysis.

A second assumption of family systems theory is that family systems, like any system, desire and need stability; too much change or chaos can result in system difficulties or breakdown. Ideologies (e.g., a family's gendered views of who should do paid or unpaid work) and behaviors (e.g., dinners with grandparents) become patterned over time, resulting in system stability. Stability is achieved through *negative feedback loops*, which discourage change. However, for families to remain viable, they must also be able to change when needed. For example, when a child is born, new routines must be developed in response to such a major change in the family system. *Positive feedback loops* encourage more of a new behavior (e.g., the adjustment of a curfew following a teenager's demands for greater independence) or new ideology (e.g., a family changing its outlook on life after a member is diagnosed with a life-threatening disease). Case researchers, through their exclusive focus on one family at a time, have the opportunity to observe and document various interactional loops that may be helping or hindering families.

Another family systems assumption is that families are affected by the broader environment or *suprasystem* (e.g., family-work policies influencing whether or not a caregiver leaves paid work to care for an ailing family member). In turn, families have their own capacity to impact the environment (e.g., employed parents collectively demanding workplace day care). Case researchers recognize the impact of context on families by pulling into their analysis factors such as the economic and political realm in which a family exists. Detailed attention to the larger sociohistorical context can reveal important educational and policy considerations.

Finally, family systems theory recognizes that the relationship between families and the suprasystem

is affected by the permeability of family systems' *boundaries*. Boundaries separate families from other systems such as the neighborhood or community. Most families have semipermeable boundaries; that is, they allow selective information both in and out of their systems. However, boundary permeability fluctuates over time. As well, the degree of permeability may change in terms of its functionality for families. For example, it may be functional for a family to become more private in an immediate response to a crisis. However, if the family's boundaries do not open up over time to allow it to access or receive help from others, such closed boundaries may ultimately impede overall family functioning. Again, case study research, with its in-depth focus on one case, allows for a close analysis of how a family system's boundaries influence family interaction and well-being.

### *Boundaries and Ethics*

Case studies of families may include an ethnographic component involving substantial time spent in a family's home. Researchers also pass through a family's emotional boundaries. Given the potential implications of such deep involvement in a family's physical and emotional space, efforts to minimize risk to the family should be paramount. Ethical issues around how to protect individuals' confidentiality need to be considered. For example, there may be times when detail is sacrificed to hide family members' identities from others—not only those external to the family but also other family members. Researchers may also need to consider how they will deal with their own emotions resulting from their intimate participation in a family's private life and how they will respectfully withdraw from the family's emotional and physical system when the research is complete. In Linda Matocha's study of families in which one person had AIDS, families came to depend on her and even view her as a family member, and she also attended funerals of individuals who died of the disease. She maintained relationships with families after the research was complete; other family case study researchers might make different choices.

### **Application**

Many types of families and family experiences can be studied using a case study design. For example,

a case study may look at a caregiver's experiences of providing care to an elderly family member, focusing on factors such as daily caring activities that need to be carried out and the impact of regional policies and local services—or lack thereof—on the family's well-being.

The coming-out process of gay and lesbian individuals is typically focused on at the individual level. However, families of individuals who are gay also negotiate a coming-out process, continually making choices about to whom they will reveal they have a gay family member. Joyce Baptist and Katherine Allen conducted semistructured interviews with six members of a family regarding how they negotiated their coming-out process. The authors noted how their case study design “honors one family's unique stories around the coming out of a gay member, including the motivations, reactions, perceptions, beliefs, and hopes of each gay member and of (the) family as an entity” (p. 95). They described complex processes of embracing a gay identity, integrating as a family, building social networks, and having a social awakening.

In 1951, three young brothers went missing after leaving their family's home for a neighborhood park. Years later, the parents had still not given up hope; researchers Deborah Lewis Fravel and Pauline Boss saw an ad placed by the parents in 1989. On the basis of this, they conducted an in-depth unstructured interview with the parents, with the goal of gaining deeper clarity into what the researchers understood about the concept of ambiguous loss—uncertainty about the loss of someone resulting in a more complex experience of grieving and resolution than what typically occurs. A 38-year retrospective account revealed various themes such as hope and working as a team. The in-depth nature of this case study highlighted resiliency and positive coping skills in the face of such an ambiguous and difficult loss, something the researchers had not necessarily anticipated.

### **Critical Summary**

Families, in their varying forms, are excellent cases for analysis. Family systems theory focuses attention on complex family dynamics, real-life processes, and the interaction of families with other systems. Although an “N” of one, a case study provides important and detailed insight into families and family dynamic.

## FICTION ANALYSIS

---

If we accept the simple wisdom of the common adage that truth is often stranger than fiction, then what might that in turn suggest about the relationship of fiction to truth? Indeed, within research traditions and perspectives that question monolithic truth claims, any distinctions between “truth” and “fiction” are inherently granular and not categorical. Thus, in its most simplistic incarnation, fiction analysis case studies use works that are considered by popular culture as well as academic convention as fictional as data for the craft of academic research.

### Conceptual Overview and Discussion

In fiction analysis cases, the fictional text is treated as a cultural artifact. The cultural artifact is understood as an effect of a given society that acts to mirror and emphasize variously chosen sets of enacted relations and phenomena of that society as situated in a distinct time and place.

Thus, the fictional text is an artifact that embodies a particular set of norms and patterns that are relevant to a given phenomenon or society. The treatment of fiction as “data” offers an

opportunity to examine text(s) that both contain and are products of their social context. Fiction analysis is a way of taking cultural artifacts, steeped in the richness of the social context(s) that allowed for their creation, and then accepting the veracity of using such artifacts as data for analysis.

Fiction analysis is closely connected with ideas concerning history. We might usefully ask, as does Ann Rigney, why we see novels as unreliable due to the fact that creative writers are less constrained by their imaginative capacity than professional historians. Does the use of archival research by such historians render an account more revealing to us, or is it simply more authoritative? Postmodern historian Hayden White has questioned the assumed authority of a “historical account” by suggesting the many similarities in the craft of “fiction” and in “history.” Though White does not deny that historians draw on historical traces to “do” history, he highlights the many parallels of historians and writers of fiction, including their interest-driven hand in selecting the events they are to describe, ordering those events, and attaching meaning to those events. Perhaps the example of fictional historians such as John Demos, who makes use of historical fiction to provide for an “inner feel” of a period, offers us some reassurance of the value of fiction as a source of data for case studies.

The resonance that we may feel in experiencing the reading of a text is important, indeed valuable. Being that fiction is an aesthetic object, our reading experience transcends simple fact gathering. Thus the complexity of interacting experientially with characters and context in fiction offers a nuanced way of revealing both how subjects experience their situation and likewise how we as researchers experience their lives. In this respect, the addition of the researcher into both the data and the analysis of a case is particularly nuanced.

Whether or not the particular fiction is specifically described as historical fiction or not is of no particular matter. Fiction is written by authors who are shaped by (through) their social context and we as readers and researchers are as well. Our aesthetic experience of reading such fiction therefore brings into light not only the various social contextual factors at work in both the creation and consumption of the fiction but also in our reaction to experiencing the similarity or differences in such social contexts.

### Application

The work of Barbara Czarniawska offers useful examples of different ways in which fiction analysis may be employed. Through such varied works of fiction as detective stories, fiction (and film) involving cyborgs, and a fictional account of a Swedish stock market crash, Czarniawska examines taken-for-granted assumptions in the social world. Through understanding that the creation of fiction does not occur in a social vacuum, she is able to show how the examples in fiction act to teach particular ways of being. The examples of how women in finance are portrayed as being subject to a classical Greek tragedy plot or how women in detective stories are exaggeratedly constructed as being dangerous offers insights we would not otherwise find in more conventional accounts of women in banking or police work.

Czarniawska is also able to use genres such as science fiction to examine theoretic suggestions. Her work examining the potential (or lack of potential) for liberation through cyborgs spans film and print media and different incarnations of, for example, *The Stepford Wives* and *Blade Runner*. In doing so, she offers an examination of different historically situated variants of the same story in contrast, with implications arising from how these accounts have or have not shifted over time.

### Critical Summary

The selection of data for analysis in case study research involves questions of usefulness, trustworthiness, opportunity for novel insights, and some sort of veracity. When we categorize documents or accounts as being either fiction or nonfiction, we invoke a latent evaluation of the data in terms of such questions. Instead of asking, "Which is true?" perhaps we might be more usefully asking, "Whose truth?" when considering fiction for analysis. If truth is indeed stranger than fiction, then the corollary seems to point toward fiction being comparatively mundane. For those who study more commonplace social situations or widely held social convictions, the potential for such data to illuminate the common, normal, or taken for granted is powerful. The treatment of fiction as data offers an opportunity to examine

text(s) that are both effects of their social context and contain that social context.

## FIELD NOTES

---

Field notes are the data collection technique for making field work into a case study that has utility in teaching and training. Without proper field notes, the translation of field work into a case study cannot be successful.

### Conceptual Overview and Discussion

Taking down field notes is the act of recording one's research data as well as the beginning of communicating one's research findings with others. The creation of a permanent record of events, interviews, interpretations, and ideas allows researchers to be clear about what they think they know. Often, in the course of discussing field work as a methodological tool, people wonder how spending time in a particular place with particular people

enabled the researcher to come to the conclusion that he or she understands something about them that they may not themselves admit to understanding. Few of us can claim to really understand our own neighbors. However, as trained professionals engaging in field work, case study researchers keep field notes and rely heavily on them as a primary source of data. Through taking down a description of an event, they create the record of an event. As Clifford Geertz describes it, case study researchers inscribe social discourse, turning it from a passing event, existing only in its own moment of occurrence, into an account, which exists in its inscriptions and can be reviewed at a later time.

There is an air of mystery surrounding field notes and what they should contain. Should field notes be a glorified diary, including the researcher's personal feelings, struggles and desires? For some, making note of any personal issue is important in that it might come to shed light on a particular phase of research. For others, keeping a research-based field notebook along with a separate, more personal journal is preferred.

The posthumous publishing of Bronislaw Malinowski's diary in 1967 brought this discussion to the fore of many social science debates. A founding father of anthropology, Malinowski was seen in full exposure, his personal thoughts and desires laid bare in a way he certainly had never intended. His notes and data were full of great depth and breadth and led to the publication of highly respected monographs in the discipline. These portrayed him as a man struggling through both culture shock and assimilation who frankly documented his feelings, which many in a similar circumstance and point in time may have shared. Some see this as a clear showing of the complexity of the human experiences and human beings involved.

### Application

Field notes can take many forms. There are the random jottings that take place when one walks from village house to village house or the notes made at a café where one sits between interviews. Some of these notes are descriptive, focusing on the physical space, the mannerisms of the people present, the sounds, smells, and duration of events. Others are merely words taken down to jog one's memory later when one expands on earlier notes. They should be

written, expanded upon, reviewed, added to, and reviewed again. For those more accustomed with a natural science model for research, this may sound strange. If field notes are a researcher's data, then how could a researcher add to them, expand on them, "change" them? Well, the techniques of observing and participating require that researchers note their findings through those field work activities and that they do so in a way that will enable them to write their theses later and provide the data to support their findings. Rudi Colloredo-Mansfeld, in his account of economic and artistic life in Ecuador, engagingly describes his note taking and data collection in Otavalo. Colloredo-Mansfeld not only relies on his written documentation of life in the artisan community, but also sketches scenes of the culture around him, thereby opening himself up as an artist and researcher in the community. Because his field notes included detailed descriptions of household goods, the sketches acted as both a field note and also as a pictorial representation of his jottings. When Alma Gottlieb and Philip Graham were in a West African village, as anthropologist and writer/partner they had multiple encounters with their need to record their experiences. Gottlieb describes her desperation to begin her orderly and systematic collection of field notes by following the census model of her advisor only to find that simple questions, and hoping for simple answers to develop into real field notes, is often easier said than done. Field workers find through their interactions with ethnographic and fiction writing that taking down reality amounts to more than simple notes.

Researchers engaged in field work must familiarize themselves with the different ideas and forms of note taking before beginning their research. Similar to the case study providing a template for thought, learning, and action, studying various methods of taking field notes can provide a menu of options for the researcher standing in a field site with an empty notebook. Yet like most elements of field work, the successful method for each individual will come only through individual experience. Through trial and error, a system is born. However, by always striving to maintain both breadth and depth in one's notes, the resulting data will create a more well-informed case study.

The breadth of field notes often comes from the breadth of the project itself. If one gathers data for 12 months in the field, it is likely that the resulting

field notes will include information on many facets of the particular culture, not just those that fall directly into the research program. However, if one is to be in the field for only a month or two, then the field notes will likely be more narrowly focused on the specific research questions at hand. In the latter instance, one might have to sacrifice breadth for depth. Focusing as much as possible on the area of research will result in notes reflecting greater detail in a smaller area of focus. Breadth can also come from the work a researcher does to expand on earlier notes or ideas. This may include reflections on other academics' research, questions that might connect the present research with the research of others in another discipline, or conversations with locals about areas that might seem to fall outside of the area of focus. In this way, field notes should not be only journalistic jottings of one's observations, but should also include those immediate thoughts, questions, or realizations one comes to while engaged in the research process. Summaries of the research and thoughts about it can be very useful when taken as an overall log over time. This is why taking time to reflect on one's notes is so critical. Through reflection and review of one's field notes, connections can be made and the data may begin to form a picture of the case study that will result. Even though the data are present within a researcher's field notes, it is nevertheless the researcher's job to organize, translate, and present them.

These days there are many options for individual researchers who want to record their field notes directly into a computer. While many field work settings make such a process challenging, some researchers find it easier to create word processing documents immediately while doing field work. Researchers often construct databases to manage their field notes. They select appropriate categories for classifying the data. For example, a cultural anthropologist might set up specific categories for kinship terms, religious taboos, plants, social networks, and so on. These data can then easily be retrieved for analysis. Some researchers rely on tape recorders or digital recorders for their interviews or field notes. However, most field workers would find it safer to transfer the information off of such recording devices as soon as possible after collecting the interview. Regardless of the kind of technology a researcher uses to collect and store field notes, the utmost care must be taken to keep the data safe.

D. W. Plath describes the underanalyzed aspect of what he calls "filed notes" and the amount of work that comes after one collects data in the form of field notes. He persuasively argues that social scientists have not given enough critical attention to the act of working with and making use of field notes. Often the necessary data are extracted and the rest is left forgotten. Plath also argues that if more time was spent with field notes, the resulting analyses and case studies would be greatly improved. Gathering all of one's field notes together and studying them, perhaps along with any personal journals, can be invaluable for seeing the evolution of one's ideas. This active reflexivity enables researchers to examine their cultural and epistemological positions. While great attention should be given to the act of taking and the quality of field notes, there must also be serious attention given to the processing of all of the field notes after data collection is complete.

### Critical Summary

Field notes comprise the data gathered in field work. Therefore, critical attention should be paid to the personal methods one employs in creating a field log and how one will strive to ensure appropriate depth and breadth in one's field notes. Because the field work situation is fluid and unpredictable, researchers must make every effort to make good use of their time and maintain the highest quality field notes possible. Once back at the desk, the field notes come to act as a guide. Through critical reflection and attention to one's field notes, the best possible case study will result.

## FIELD WORK

---

Field work involves a complex process of observing and participating in another culture. Unlike the relatively simple act of observing, the union of engaging in local daily life while being observant is at the core of the field work experience. Field workers both observe the activities taking place in the community and participate in them as much as possible and as appropriate. The crafting and use of case studies relies heavily on the experience, description, interpretation, and presentation of field-based research programs.

### Conceptual Overview and Historical Background

Field work, as a data collection method, is particularly useful for researchers who wish to involve themselves in collecting and analyzing information about people, such as their activities, beliefs, and attitudes. Since most social scientists are concerned with the study of living people or cultures, researchers need to collect firsthand information, often by living in the societies that they study over lengthy periods of time. The method of field work was developed in anthropology as a result of some of the earliest anthropologists transferring their ecological or natural science training into the science of studying people in their natural environments. An example is Sir Walter Baldwin Spencer, a biologist who traveled in Australia in the late 19th century to study the natural flora and fauna. Through making the acquaintance of Francis James Gillen, an Australian anthropologist/postmaster who lived in the outback, Spencer began to make notes about and study the Australian aboriginal population as he had the plant species of the area. This kind of attention to people in their traditional setting, known as “field work,” became the hallmark method of anthropology. Most graduate students in the discipline complete a period of field work as part of their rite of passage in becoming professionals in the discipline. Field work, therefore, is a highly valued, and sometimes misunderstood, research method.

The monographs resulting from field work are often referred to as *case studies*. These portraits of cultures are used in teaching from the undergraduate

to the graduate level with great success. Since most usually cover a similar host of topics, such as subsistence practices, gender relations, political structures, economy, ideology, and so forth, readers are able to compare and contrast case studies with one another. Other academics have also found such monographs useful for these often draw together streams of inquiry—economic, psychological, historic, and social—in a uniquely cross-cultural format. This breadth lends itself nicely to engaging other researchers’ own questions. For the general public, there is always a place for learning about how other cultures live. Margaret Mead found great public success in publishing her account, *Coming of Age in Samoa* in 1928, which described adolescence in Samoan culture and raised many questions about Western assumptions of this stage of the life course. While the particular focus of each researcher in his or her field site is likely different, the general macrolevel discussions are made possible through field work–based case studies.

### Application

Field workers usually live in the community they are studying, sometimes renting a house or a room in someone else’s dwelling. It is argued that through this intensive participation the researcher becomes deeply familiar with the group and can understand and explain the society and culture of the group as an insider. Of course, many researchers find being alone in a foreign place where the native linguistic skills and the practices and rhythms of local life are unfamiliar a very stressful experience. The culture shock that can arise in the field work experience is a pertinent issue and as a result very well documented. If a researcher withdraws for too long and finds the field situation too challenging, then he or she may not be able to collect the data necessary to successfully complete the research project. Therefore, merely arriving at a field site in order to participate and observe a bit does not guarantee success. For researchers to continue working on their projects in the midst of culture shock, they must have adequate training so that they can anticipate what may arise in their particular field site and deal with it the best they can. This training may arguably be subtle in comparison to training for other research methods, but it is, nevertheless, critical. Case studies that can train students for field work are critically impor-

tant tools that can enable individuals to work through various field work scenarios before actually embarking on their own field work.

Students of qualitative research methods often remark that detailed stories about field work are most interesting and helpful as they embark on their own research. They state that when they are in the field they remember stories—particular case studies, if you will—and they often recall how a researcher managed in a particular situation, and this helps guide them. Of course each field work experience is generally quite individual and unique, therefore there is no prescription for success that an advisor or consultant can provide a researcher. The case studies that one chooses for discussing field work can cover theoretical, geographic, cultural, or disciplinary areas of overlap. Lynne Hume and Jane Mulcock have edited an excellent volume that gathers together numerous accounts of anthropologists in the field and their experiences with things like depression, hostility, danger, and moral dilemmas while engaged in field work. Field work, then, is an ongoing, multifaceted research experience.

Field work is usually undertaken because the nature of the problem or theoretical topic chosen by the researcher can be best addressed through such a research program. For example, during Spencer's era in the early 20th century, researchers studied cultures with the goal of describing them in as much detail as possible. In recent decades, anthropologists have been focusing more on problem-oriented research. Some are committed to scientific and causal research to explain aspects of culture that sometimes seem "unexplainable," such as why some cultures prohibit eating certain foods for religious reasons. Other anthropologists favor more intuitive research that avoids hypothesis testing and favors evocative interpretationist descriptions in search of symbols, motivation, and meaning; for example, how particular cultural groups interpret their personal experiences and create meaning in their lives. For example, Philippe Bourgois, who studied drug dealers in East Harlem in New York City, found that his experiences on the street, living and doing field work in *El Barrio*, moved him to consider how the situation he was studying was a form of what he calls "inner-city apartheid" in the United States. Eric Ramirez-Ferrero moved beyond traditional forms of

economic analyses of the farm crisis and uses emotions and gender to interpret the causes of suicide among male farmers in Oklahoma.

### Discussion

Despite some early criticisms that both field work and anthropology focused on the discipline were not scientific enough, anthropological researchers engaging in field work are actually employing the scientific method, a logical system used to evaluate data derived from systematic observation. Sarah Franklin encourages us to reconsider what science is all about when she writes that anthropology can foster an understanding of science as a form of culture. Researchers rely on the scientific method to investigate both the natural and the social worlds because the approach allows them to make claims about knowledge and to verify those claims with systematic, logical reasoning. Through critical thinking and skeptical thought, scientists strive to suspend judgment about any claim for knowledge until it has been verified. Field work can be used successfully in either inductive methods of research or in deductive methods. In inductive methods, researchers first make observations and collect data. Researchers use the observations about different variables to develop hypotheses about the data. In contrast, the deductive method of scientific research begins with a general theory from which one develops testable hypotheses. As with the inductive method, the testing and retesting of hypotheses and theories is used to ensure the reliability of observations made. Researchers may also use a more interpretive lens in their methods. Much field work relies on the assumption that we need a form of interpretation that does not turn our informants into objects. Paul Rabinow addresses this problem in a book based on reconsideration of his own field work experiences. Rabinow suggests that, for the field worker, coming to understand the cultural other involved coming to understand the cultural self.

Through these methods of field work, researchers do not arrive at absolute truths. Theories may be invalidated or falsified by contradictory observations. If research results from field work in rural Russia showed that farmers were hesitant to engage in individual farming and it was argued that in the postsocialist situation in Russia private farming

would fail, but another researcher's field work found a blossoming entrepreneurial spirit among individual farmers elsewhere in Russia, then one would have to begin the task of assessing the variables in the different field sites. Using case studies resulting from field work in two different areas would be helpful. For example, in Siberia many villagers expressed greater hope and potential for the economic effects of postsocialism than the villagers in Central Russia. Though the residents are all living in a post Soviet context, John Ziker found that the discourse of the Siberians was centered more on ideas of indigenous peoples returning to "traditional" forms of economy such as owning their own reindeer herds, whereas in Central Russia, Patrick Heady and Liesl Gambold Miller found that villagers who relied on agriculture viewed agricultural reorganization as a collapse of the social safety net the state had for so long provided them. While one generally finds that there is some continuity from one case study to another within a common cultural region, there can be remarkable variations, and successful field work is a method that can uncover some of the reasons behind such differences.

Margaret Mead, perhaps the best-known anthropologist and an extraordinarily active field worker, often referred to the field worker as engaged in building a systematic understanding of the culture resulting in a living, changing, analytic system in which new data gathered in the field can be placed. Mead was identifying the protean nature of field work much as Bronislaw Malinowski, one of the greatest social anthropologists of the early 20th century, had regularly noted the need to review his field notes in order to keep his gaze sharp during his field work. While field work makes possible the deeper understanding of a particular place or people or problem, the researcher must always keep in mind that, like culture itself, the field is always changing.

## FORMATIVE CONTEXT

---

*Formative context* refers to a set of assumptions, arrangements, and shared ideas that exist to produce and preserve a particular version of social life so as to make routine behavior and existing structures seem permanent. Formative contexts are not static; they differ in their susceptibility to change as a result of social conflict.

### Conceptual Overview and Discussion

Case study research is said to be most amenable to an examination of unique or transformational events. These events help develop an understanding of complex social phenomena by thoroughly investigating the rich detail of the case. However, at least one question remains: How is social life held together when the exceptional recedes and is replaced by normal activity? The normal, according to the social theory of Roberto Unger, is just as informative and interesting as the exceptional, because the normal contains within it the seeds of

its own eventual transformation. The formative context of society and social relations is the lens through which transformation and permanence can be better understood as being conditional. For Unger, existing social theory does not recognize this conditional and contingent nature of society.

According to Unger, existing social theory can be categorized as either radical or positivist. Radical social theory posits that society is created, reshaped, and reformed by the human mind and that societal change will take place through revolutionary means. Since there is no underlying natural order that predetermines human relations or the structure of society, the individual has at least the opportunity to imagine him- or herself as being free from the social structures that currently exist. For the radical, the only way to switch to another arrangement is through revolution. However, the emancipatory social theory that has these underlying views has not seen this logic through to its conclusion. One can see radical theory, and its limitations, in practice by noting the absence of the definitive yet elusive final change as envisioned by Marxism.

At the other end of the spectrum is a positivist social science that has come to deal more and more with individual problem solving, and with narrowly defined searches for understanding that have abandoned the quest for a larger understanding of society. This social theory takes existing arrangements as given and unchanging, rather than as transitory and evolving. For example, the nearly complete global monopoly of liberal democracy in politics has been said to signal the end of history. In other words, nothing can be conceived that could replace democracy as a political system: It is a given, and unchanging, form of social life.

Unger notes that this combination of messages that give the individual the potential to shape society with messages that society is static results in a certain intellectual and societal dead end. Unger offers us a release from this deadlock by exposing the importance of formative context in determining how existing social or institutional arrangements were formed and are maintained. He argues that human motivation never fits perfectly within the institutional, economic, and social structures that exist in the world at a given point in time. As a result, there is a potential in the small adjustments of everyday routines embedded within a

context that can give rise to a chance of changing a context. This enables us to see that the regular and routine activities of society are not general laws. Key to this explanation is the idea of formative context: Formative context places unique and transformational events at the center of understanding how society both maintains and transforms itself. Unger's social theory takes this view and develops it into a theory of social relations with three elements: context provides a certain conditionality to any social arrangement; people have the flexibility to break the existing context; and contexts impose different levels of limitation on our activity. For clarity, it should be noted that context and formative context are different concepts: The former describes the circumstances around any given social situation, while the latter is concerned with how social arrangements are conceived and perpetuated.

Therefore, formative context provides the case study researcher with a theoretical framework for investigating everyday routine as well as transformational events. It accomplishes this by rethinking two opposing ways of questioning social relations. On the one hand, the question is asked: How is society held together? On the other: How does society change? Rather than viewing these as mutually exclusive, formative context regards them as two sides of the same coin. By fusing these supposedly disparate questions, formative context provides a framework for defining the nature and limits of the routine activities of everyday life. Therefore, adopting this approach allows for a detailed examination of the how and why questions so amenable to case study methodology. Furthermore, seemingly normal events or social situations are infused with the possibility of hidden uniqueness through a detailed examination of how they have come to be regarded as routine. Unger refers to these as context-preserving routines.

Formative context also recognizes that the small adjustments of everyday routines embedded within a context can give rise to a chance of changing a context. The result will be another context and an altered set of routines. This is what Unger refers to as context-transforming conflict. There are limitless numbers of these possible contexts, and so no one version of the truth holds greater or lesser validity. When applied to case study research, this aspect of formative context can help the researcher

who has adopted a longitudinal or time-series approach to case study methodology. It can also provide alternative explanations within a particular case study. Thus, the use of formative context can contribute to meeting some of the hallmarks of exemplary case study research.

However, this last aspect of formative context, namely, the limitless numbers of potential contexts, also signals a limitation. On this point, formative context has been critiqued for taking an “anything goes” approach. Therefore, when choosing to adopt formative context in case study research, it should be considered a tool best used as part of a convincing and well-justified narrative of the situation under study.

### Application

Given formative context’s emphasis on change and routine, it is perhaps not surprising that most of the research done utilizing the concept has been in the area of introducing new information systems into organizations. This is because the introduction of new information systems often forces an analysis of existing routines and their possible change. With this in mind, one exemplary piece of case study research in the information systems literature that utilizes formative context is found in Dick Stenmark’s examination of the introduction of an intranet at Volvo Car International (VCI).

For more than 20 years, e-mail had been successfully and extensively used by VCI throughout its many work sites. However, the use of a somewhat different technology (the intranet) was not readily adopted by workers. To explore why this might be, Stenmark embarks on a case study of VCI utilizing formative context as a theoretical framework. He uses case study methodology to collect data by examining relevant documentation and interviewing workers. Of note in this example is that the case study problem and event are not particularly unique or transformational within the context of the implementation of a new information system. Employing formative context as a theoretical backdrop enables a rich analysis of the events surrounding the change in the organization, and helps the author achieve two objectives.

First, through an examination of the routine activities of workers, assumptions and arrangements are exposed that make clear why the existing

technology structure of “e-mail only communication” is preferred. Second, it shows how the introduction of a new technology broke down existing routines, created a conflict, and eventually resulted in a new formative context through the adoption of the intranet. Stenmark concludes by noting that although the existing order of e-mail use seemed natural, the application of formative context highlighted that this naturalness was socially constructed.

Another exemplary piece of case study research using formative context can be found in the work of Claudio Ciborra. Information technology changes rapidly, and successful organizations are characterized as those being able to adopt and adapt to new technology. However, Ciborra argues that, in practice, successful adaptation to change due to the adoption of new information technology is never easy. Instead, it requires changes to the background assumptions that existed to maintain the use of the previous incarnation of information technology.

To illustrate this argument, Claudio Ciborra and Leslie Schneider use a case study approach in their 1992 article. The case looks at changes to the organizational structure of a research and development department of a software firm. The firm was given a new project: to develop a complex new computer system. Hoping to increase productivity and improve the organization of the work on the project, management introduced a more structured approach to software development. The work was divided into components, each with specific goals and activities required for completion. The firm also introduced a suite of communications tools for their programmers that supported their work on the project. The introduction of a more structured approach to software development failed to achieve its stated goals of productivity improvement, while the introduction of communications tools for programmers was deemed a success. The case argues that the communications tools were a success because they were an enhancement of practices that already existed below the surface of the organization, such as informal knowledge exchanges and sharing of programming code. Using the lens of formative context, it seems apparent that the informal communication tools were part of the taken-for-granted routines and behaviors of the organization. The introduction of the

suite of communications tools reinforced these existing routines, while the new hierarchical structure challenged the routines, albeit unsuccessfully. In this case, formative context is used as an explanatory mechanism: It shows that the introduction of a hierarchical structure was unsuccessful because it did not recognize the background assumptions that existed to maintain the current formative context.

### Critical Summary

Formative context is most amenable to case study research where there is potential for investigating the hidden assumptions of everyday routine, where seemingly permanent social structures could be revealed to be socially constructed, or where conflict opens the possibility of changing routines and context. Unlike other social constructionist approaches, Unger's formative context does not assume that the existing social structure is ideal, nor does it expect that any future structure will be any better. Rather, it anticipates a situation where the process of context setting itself becomes transparent and routine, and as a result powers and rights are never considered permanent.

Outside of Unger's social theory and the research in information technology as exemplified by Ciborra and by Stenmark, little else seems to exist to guide interested researchers on its use in case studies. But, with careful consideration of its limitations and utilizing the limited extant examples in the literature, formative context could be applied to case study research in any area of social science.

## FRAME ANALYSIS

---

Erving Goffman's frame analysis provides a microsociological lens on how we make sense of the encounters around us. Our experiences are governed by frames that are essential for understanding the organization of experience. Frames define what is meant by certain social events and how significant we consider them to be, and they provide guidelines on how to interpret events. Frame analysis can assist the researcher in understanding how people construe events and in understanding observations made of interactions between respondents. It can also be used for gaining understanding of the dominant framing within and between social movements and social institutions.

### Conceptual Overview and Discussion

Goffman, a Canadian sociologist, is well known for such classic works as *The Presentation of Self in Everyday Life* (1959), *Asylums* (1961), *Stigma* (1963), *Forms of Talk* (1981), and "Felicity's Condition" (1983). It is argued that Goffman was one of the first to present thoughts on public spaces, the socially constructed self, the division between private self and public identity, and the role gender plays in society. With another major work, *Frame Analysis* (1974), Goffman presents a complex, highly detailed, and conceptualized analysis of frames that we use every day to make sense of what is happening around us. He vividly draws on huge amount of examples, varying from card games to theater to news clippings, to show what is it that we think is real, how we interpret what is happening, and under what frames.

*Frame Analysis*, together with *Forms of Talk*, marks Goffman's linguistic turn, due to which Goffman has gained wide interest outside sociology, as well. Varieties of frame analysis have been used, for example, in psychology, linguistics and discourse analysis, media and communication studies, and policy studies and political science. The attempts to neatly categorize frame analysis

have proved to be unsuccessful. Does it fall under ethnomethodology? Is it more about semiotics or symbolic interactionism? What is the role of structuralism? Or should it be called interpretivism? Whatever the case, Goffman was above all intrigued by encounter-based analysis of everyday social life. Thus, it is not reasonable to try to apply Goffman's ideas to narratives and stories, or to other second-hand versions of events. Fine-grained studies in situ are the essence in Goffman's work. Perhaps that is one reason that frame analysis is rarely utilized in, for example, organizational research. It is argued that in the field of organization studies Goffman's ideas would prove to be fruitful for those engaged in empirical research of naturally occurring human interaction.

With frame analysis, Goffman offers a perspective on social reality, asking "What is it that's going on here?" and "Under what circumstances do we think things are real?" Shortly put, frames (often also referred to as cognitive structures or mental schemas) organize meanings, provide schemas to interpret events, and guide both individual and collective action. They act as rules for our communication and cognition. The way an activity is framed directs how we relate to it. Thus, frames are essential in order to understand the organization of experience. Intriguingly, although the employed frame is implicit and participants unaware of it, that does not prevent them from acting upon it. This specifically surfaces in encounters with authority, due to strong underlying legitimating frames that are more often than not taken for granted.

The principles by which experiences are subjectively organized include primary frameworks, keys and keyings, and designs and fabrics. Primary frameworks allow their users to perceive, locate, label, and identify occurrences in users' terms. They can be broadly divided into natural and social frameworks. Natural frameworks present events as results of natural determinants. As such, they cannot be judged morally. Social frameworks carry assumptions of deliberate aim, will, and control of the event, and are thus subject to moral judgment. All social frameworks also involve rules. Both natural and social frameworks can be placed along a systematization continuum. At one end, frameworks are defined through an organized system of rules, postulates, and entities, whereas at

the other end they do not employ any specifically articulated shapes, but provide only some perspective, approach, or understanding. Primary frameworks are thought to be real and actual; that is, actions framed in terms of them are thought to be really and actually occurring.

Primary frameworks are subject to two transformations, keys and keyings, and designs and fabrications. In contrast to framing, keys and keyings transform the literally appearing meanings of an activity to something else, mimicking, but not fully duplicating, the primary frameworks. For example, an utterance may be taken to represent a genuine expression of one's feelings or it may be keyed as irony. Keys and keyings can vary according to the degree of transformation that they produce, and are themselves subject to rekeyings.

Designs and fabrications are intentional efforts to manage activities such that they will be interpreted in a wrong way by other people. Alternatively, people can delude themselves through illusions. Thus, designs and fabrications are meant to cause a false sense of reality. Fabrications can be benign, meaning that they benefit or serve the interest of the person contained by them. Exploitive fabrications are hostile by nature.

The process of framing is bidirectional, playing with both structure and agency. Our experiences and events are not only framed, but we equally frame experiences and events. For Goffman, frames are a central part of culture and they are institutionalized in various ways. Framing can be seen to act as a bridge between culture and cognition. Although culture provides us with certain frames, we actively process, encode, and decode our reality in different ways. This makes the whole framing process vulnerable to the potential for struggle, and a site of multiple realities.

Goffman was first and foremost interested in the question of how social reality sustains itself. Reality for him was always mediated, changing, and uncertain. In fact, there is not often any objective reality into which the frames are anchored. By anchoring an activity, a sense of reality can be generated. This, however, does not unframe activities or make them invulnerable to misconstruction. The subjective reality and the importance of framing become specifically evident in informal social relations when making character judgments. We do not simply perform our selves, but the selves are

products of the framing of our performances and actions. Thus there is no way we can unambiguously check if our judgments of other people's characters are accurate, or, respectively, as judged persons, to argue against ill-fitting frames. In a similar vein, when talking informally, we can quite freely choose what we tell about ourselves and how we present our experiences. This makes the nature of informal talk dramatic and particularly vulnerable to frame manipulations.

The views people hold on the question, "What is it that's going on here?" are very likely to differ. In most situations, different things are taking place simultaneously, complicating what is meant by *it* or *here*. For example, when talking about "the current situation" or something happening "here," we should clearly know and agree on what it is that we are thinking about and referring to. Even single words, or sequences of words, can have multiple meanings. With attention to context, we can often rule out the incorrect interpretations and rule in the correct ones.

### Application

Due to many branches of frame analysis, there is a lack of coherence of how frame analysis is to be applied. Different methodological aims abound, and alongside Goffman's idea of frame analysis there are numerous other forms of analyses that fall under the same rubric. The problem often is that it is difficult to distinguish whether it really is Goffman's frame analysis that is applied to a study, or if it is just another loose variation of that, as there is no adequate systematization of different approaches.

Frame analysis has gained ground especially in the study of political communication, ideologies, policy making, and media discourses. In the study of social movements, the cultural aspects and discourses of a movement have been of wide interest. Attention has focused on symbolic constructs and how they are used to shape reality in a particular way, that is, how reality is negotiated, constructed, and reconstructed. Furthermore, framing processes are seen to be central in understanding the dynamics of social movements.

In addition, special cases have been investigated using frame analysis. The realization of sustainable development in transport policy discourses, and

the discursive framing in environmental policy debates have been under examination. Goffman himself extended frame analysis to the study of gender in *Gender Advertisements* (1976) and in "The Arrangement Between the Sexes" (1977), the legacy of which has been later continued by other writers, as well.

### Critical Summary

People's different interests define what is motivationally relevant to them. Thus it is crucial to know how we reach agreement on what things are; experiences are never purely one's experiences. It is also argued that the interpretations people make are subject to their previous knowledge about other people, themselves, and social situations. History cannot be escaped, as it is often critical to the interpretation process. Goffman's frame analysis is criticized for not paying enough attention to the existence of multiple realities of different individuals and thus for assuming that interpretations can be frozen into single acts. Further, it is argued that the events Goffman is interested in (plays, commercials, drama, etc.) belong to the periphery of everyday life; that everyday behavior and interaction are indeed beyond the scope of frame analysis. It is also suggested that Goffman does not adequately consider how frames come to be developed in the first place, by whom, under what conditions, and under what constraints.

If we consider all our relations to be primary, if we believe all the news we hear is trustworthy and all the data we encounter are clean and clear, then Goffman is not the one we should lean on. Goffman argues that momentarily we may think that what appears to be really is what is going on. However, what is in fact happening is only a mistake, a misunderstanding, an accident, a dream, or a deception. There is not much in our everyday lives that is not a copy or a fabrication of what we think we should do or be in each situation. We reflect against the reality presented to us, drawing from our collective sense and representations; we are not free to frame our experiences any which way we like.

What happens when the frames we employ are incorrect or subject to vulnerabilities? Goffman is interested in why our sense of what is going on is so susceptible that a variety of rereadings is needed,

and what is it that causes incorrect framing and vulnerability to happen? At its extreme, vulnerability can lead to frame traps. When one's actions are misframed, the wrong interpretations need to be corrected. If this fails, the misframing is confirmed with any new piece of evidence or with attempts to correct the misunderstanding. Eventually, the individual becomes trapped in the web of falsifications. But, as is suggested elsewhere, the unsuccessful (or partly successful) encounters are in fact the most revealing and interesting accounts of face-to-face interaction, that is, the ones that result from misunderstandings, role confusions, embarrassments, and other frame breakings. Finally, it is good to note that there are quickly changing frames in everyday activities themselves, although they tend to be taken for granted.

## FRONT STAGE AND BACK STAGE

---

In the 1950s, Erving Goffman introduced the terms *front stage* and *back stage* into the lexicon of sociology and anthropology. As is commonly understood in the social sciences—and even in popular culture, today—social actors play roles, and do so in relation to others. A social actor who undertakes a role performance that is directed to others (i.e., an “audience”) can be said to be on stage in front of them. Front stage, in short, can be described as where a role performance is given. When that actor leaves the audience and steps out of the role, he or she goes back stage. Goffman argued for a “dramaturgical” perspective, using these conceptual tools to shed considerable light upon the detailed dynamics of routine social interaction. This pair of concepts is particularly relevant to the case study method, insofar as that research strategy invites informal data-generation techniques undertaken in naturalistic settings.

### Conceptual Overview and Discussion

An elaboration of these twin terms offers a deeper appreciation of the performative aspect of social

behavior. Role-playing involves communication, some of which is linguistic, denotative, and instrumental; here, impressions of the self (and, for that matter, others) are, in Goffman's terms, "given." Actors also "give off" impressions, largely through nonverbal significations, which appear to be less governable and thus more trustworthy. Effective role-playing, however, requires a demonstration of competency at both levels, and consistency between them. In short, on the front stage, social actors will need to manage the impressions they present to the audience (i.e., those to whom the performance is directed). Social behavior is crafted; it is work. Back stage is the arena in which the demands of a given performance are relaxed, where one can abandon the "front," or claims, put forward in that performance. In other words, the back stage can be located only with reference to a particular front stage. (Logically, of course, what is back stage to one performance can be the front of another.) Social life is comprised of ongoing series of variable and varying appearances on stage.

An acknowledgment of the impression-management process intimates that social behavior is contrived, and that an actor's *real* thoughts and feelings emerge only back stage. Such an inference is unwarranted, however. Roles are socially constructed (created by people), but they need not be performed cynically; that is, an actor may believe in any, all, or none of the fronts that he or she projects in the course of social interaction. Indeed, Goffman was not concerned about splitting ontological hairs. Long before the postmodern turn in social science, dramaturgy recognized that social reality is essentially intersubjective, which is to say, comprised of shared perceptions/understandings (i.e., definitions of the situation). Goffman's framework is meant to examine how credible performances, "fronts," are maintained (with the proper settings, props, clothing, physical appearance, demeanor, teamwork, etc.) or, alternatively, disrupted (e.g., by sheer error or the defections of teammates, those whose task it is to present a united front). Consistency is also imperative within any interaction event, and any front will have to be sequestered from contradictory ones, lest discrediting role conflict—or inconsistent role demands—develop.

The dramaturgical metaphor highlights the complexity of social behavior: its multidimensionality, its multivocality, its sometimes ambiguous

and ambivalent character. It is just these facts that make social research troublesome and apparently unscientific; and it is this messy, turgid reality that some social-research strategies aim to overcome. Researchers who are comfortable working in the positivist tradition seek to delineate an extant, objective reality (though they now resign themselves to "agreement reality," or observations stripped of *personal* subjectivity). In order to generalize and ultimately explain social features (e.g., beliefs, attitudes, stances), positivists must *reduce* social complexity. One reductive device is the experiment (fabricating conditions under which observations can be made of a specific set of prearranged tasks). Another is the closed-ended survey, where participants respond, in the abstract, to questions that define the variables under study. For each question, the respondent chooses, from among those offered, an option that fits (or "comes closest to") her "true feelings." These choices become the data that, as Howard Becker has put it, serve as proxies for states of mind that we can observe only indirectly. The result is explanation based on *thin* description (i.e., without context and nuance as opposed to the thick description that comes with richness of data). While the case study method is not synonymous with qualitative field work, its delineated focus favors such a nuanced, in-depth approach to data generated in naturalistic settings. Attention to front and back stage, and the relationship between them, adds depth and richness ("thickness") to data, which the case study method can accommodate.

### Application

The dramaturgical terms are especially useful for research undertaken in socially differentiated settings—where each actor juggles myriad roles. They are crucial for making sense of hierarchical structures (e.g., businesses and other bureaucracies, or stratified communities). Their utility was, for example, aptly demonstrated—not long after their introduction—in Gerald Berreman's analysis of caste principles and practices in an Indian Himalayan village. Where inequality prevails, not only is there much at stake interactionally, but front and back stage "realities" are apt to be sharply at odds with one another. The ability to access, appreciate, and compare regional performances is a methodological

must, if analysis is to avoid oversimplification and misrepresentation. In this regard, the work of James C. Scott deserves note. Renaming front- and back stage behavior as “public” and “hidden” transcripts, respectively, he has shed light (not uncontroversially) upon the concept of hegemony (i.e., ideological compliance of subservient people) and forms of political resistance, casting serious doubt on data derived from official sources or through arm’s-length techniques.

### Further Implications

Ironically—or, perhaps, not—and finally, just as researchers observe and interpret others’ performances, hoping for access to the back stage, they too take the stage before their audience of research participants. The researcher’s impression-management skills—limited by embodiment issues, that is, ascribed traits that “give off” impressions—will impact significantly upon the data that can be generated through interaction. They must be taken into consideration.

*explanations*. Specialist versions of functionalism or references to *functional properties* are sometimes used that are more precise in their target. For example, in sociology, functionalism refers to the notion that societal structures function for the survival of society as a whole, a tradition heavily dependent on the work of Talcott Parsons. In the philosophy of mind, functionalism was influenced by, among others, Ned Block, who characterized mental states as functional states. This was habitually related to the metaphor of the computer, namely that functional states were, in some sense, like computer programs. More generally, however, functionalism as an explanatory strategy is ubiquitous in the social sciences in a form that is “heuristic” or indeterminate. This is a form of functionalism that uses categories of explanation that describe functions without any commitment to what these categories are as objects. In this sense case studies, field studies, and experimental research all make use of a similar strategy. This discussion of functionalism uses examples drawn mainly from psychology, but they can be generalized across the social sciences.

### Conceptual Overview and Discussion

Functionalism emerges in the 19th century from studies in biology and physiology where function is placed above anatomy in importance. The discovery that biological functions cross multiple organs meant that knowledge of organ structure alone was insufficient for knowledge of *how* the body functions. Furthermore, early proponents of functionalism, such as James Rowland Angell, attributed the view to Herbert Spencer and Charles Darwin. A number of historians of psychology have claimed priority for functionalism in psychology by noting that functionalism became a unique school of psychology in the late 19th century. This was due largely to John Dewey’s well-known 1896 publication promoting functionalism as a solution to a debate concerning the interpretation of reaction time research in the 1890s. He argued that it made more sense for the psychologist to orient his or her attention to acts or functions, rather than stimulus and response, where the latter could only be teleologically associated with sensation or movement. Furthermore, individual functions were coordinated within the sequence of acts by both attention and sensitivity to the environment and by virtue of

---

## FUNCTIONALISM

---

Functionalism in the social sciences is the general thesis that phenomena can be explained strictly with reference to what they do rather than what they are. This is the general orientation of *functional*

the forward momentum of continuous activity. Dewey's functionalism was taken up as an important and novel position in psychology, but only in name. His psychology was never adopted, save in a piecemeal fashion by his followers, and would soon be overshadowed by behaviorism. Functionalism, in the hands of Angell and others, became established as the psychology that concerned itself with mental activity and biological processes.

In sociology, Émile Durkheim expounded a version of functionalism at about the same time. His version was substantially different from Dewey's, however, since it was concerned with the contribution a "social fact" makes to the needs of society. Sociologists continue to use various forms of *functional* and *functionalism*. In biology, too, the notion of a function has received widespread attention in recent decades and is used to describe the "functions" of organisms or their subsystems. Other disciplines have also made use of the terms, borrowing in various ways from biology or other social sciences.

Modern functionalism reentered psychology explicitly in the form of a thesis derived from cognitive science and philosophy, which argued that mental states were not only real but also capable of exerting causal influence. According to Block this was a thesis about the differences between mental and physical properties such that mental states were considered by their function rather than their constitution. One consequence of this view was the claim that functional states could be "multiply realized." This referred to the notion that a computer, human brain, animal brain, or "Martian brain," for that matter, could all be in the same state (e.g., pain) despite having very different physical states that realized these states of pain. This version of functionalism was attractive to cognitive scientists looking for a way to show how nonphysical states could cause physical states and vice versa.

Sometimes an additional requirement is added to this form of functionalism, namely that the functional state be "characterized extrinsically." This means the functional state has to make a difference in the observable states. Hence a functional or unobservable state between a stimulus and response counts only if it can make a difference observationally. What actually counts as a functional state is not relevant to this claim; functionalism is entirely

agnostic with respect to ontology for the sake of explanatory expedience.

### *Indeterminate Functionalism*

Within the social sciences, the use of functional descriptions is ubiquitous. This applies to almost all forms of research and hence also to case studies. Most descriptive categories rely on some version of functionalism that is noncommittal with respect to what the object of investigation actually consists of. Objects and properties are not realistically but *heuristically* defined. Such heuristic, functional accounts can refer to cognitive, social, behavioral, or even psychodynamic entities and these can be fused in turn to biological or neuropsychological accounts. Hence the claim that functional descriptions make no commitment to real entities; they are ontologically mute. However, this is also their power; namely, they are flexible and can be expanded indefinitely. For example, modularity in cognition refers to functional (mental) properties, just as notions such as short-term memory do. Their presence must be inferred from functions. The field of personality psychology is populated with thousands of functional entities (e.g., self-presentations, expectancies, self-definitions, self-verification, infrahumanization, and so on, being examples from recent volumes of the *Journal of Personality and Social Psychology*). The literature on clinical psychology, developmental psychology, and so on, would generate equally long lists of functionally defined entities that are almost wholly described by procedural fiat. (Perceptual and psychophysical theories are more complex and hence not included in this discussion.)

These functional entities are largely invented anew at a high rate and their relationship to one another is not always of concern to researchers. Functional accounts are both useful and limited. They are useful because their inherent flexibility and manner of reproduction allows even the neophyte to produce research topics and research studies. Furthermore, there is in principle no restriction to the kind and degree of functional entities that can be introduced and elaborated theoretically. They are limited because they encourage a proliferation of hypothetical entities such that there is little observable progress or concern for the ontological status of these entities.

The indeterminate nature of functional explanations is not relativistic. There is typically some empirical content that grounds such explanations in any *individual* case study or experiment. For example, we have descriptors for memory processes that are produced empirically in any one study or research program. We do not have an empirical limit, however, to the extent and kinds of descriptors that can be generated; that is, the pool of functional entities to describe memory remains indefinite. A quick perusal of the literature informs us that we can use such functional descriptors as sensory, short-, and long-term memory; autobiographical memory; and recognition memory, as well as numerous models of memory and attendant processes such as encoding, maintenance, retrieval, and so on. Each of these terms is frequently associated with a particular research program and sets of methods that have come to define the content of the program. What they do not commit to is a particular object called “memory,” nor do they elucidate the nature of individual acts of remembering.

### Critical Summary

Indeterminate functionalism, sometimes called heuristic functionalism, or role functionalism, is said to be in danger of sliding into dualism or radical reductionism. It potentially slides into dualism because it does not commit itself to real properties and hence can be viewed as immaterial. It is in danger of sliding into reductionism because it carries a promissory note claiming that eventually functional entities will be known in a fully reductive fashion. That is, once properly understood, a functional account will one day give way to some version of neurophysiology (at least in psychology).

A strictly reductionist account would end up eliminating the very phenomena of psychology that we want explained.

In sum, the capacity to multiply functional entities indefinitely makes the process open ended without seeming anarchic. Furthermore, without a commitment to the kinds of processes that are psychological, the discipline moves between the Scylla of dualism and the Charybdis of reductionism. At the same time, the extrinsically characterized, functional conception of entities ensures that fields of inquiry continue to be preoccupied with the search for mechanistic-like properties that can be multiplied across research studies. Hence, for these and other reasons, this version of functionalism works to maintain a certain unified sense of what constitutes a psychological object or property and how is it to be explained.

## GENDERING

---

Gendering is the process of ascribing characteristics of masculinity or femininity, femaleness or maleness to a phenomenon (i.e., a role, position, concept, person, object, organization, or artifact), usually resulting in power and privilege, voice and neglect, or advantage and disadvantage, as drawn along the lines of sex and gender.

### Conceptual Overview and Discussion

The process of gendering serves to create something that is “gendered”—that is, that causes a division based on sex or gender and that privileges one sex or gender, thereby silencing or suppressing the other. For example, the role of nurse is significantly gendered in that it is generally expected that a woman would possess the feminine characteristics thought necessary to carry out the role successfully. It is said that women possess an advantage when it comes to hiring and promotion in this career. The opposite occurs in the gendering of occupations such as engineers and chief executive officers. Studies demonstrate that men are privileged in such occupations, due to the traditionally male characteristics deemed necessary for success within such positions.

Several organizational theorists have written about the genderedness of organizations in their entirety. By this, they are referring not only to gendered positions as discussed above, but to the structures, roles, rules, policies, relationships, and identities that are privileged or silenced due to the

characteristics of sex or gender ascribed to them. Much research has been done on the genderedness of organizations, as related to issues of the presence of gendered structures, policies, and procedures, as well as the outcomes of such. As a result, researchers have identified what gendered organizations look like and the impact on disadvantaged groups (i.e., job segregation, underrepresentation of disadvantaged groups in management, glass ceilings, mommy tracks, etc.). Despite the fact that organizations have been identified as being gendered for quite some time, researchers are still trying to better understand the processes responsible for the creation and maintenance of these gendered organizations—that is, the *gendering*.

Central to the development of this research is the more recent (within the past two decades) notion of gender as a dynamic process. Candace West and Don Zimmerman were instrumental in shaping this new understanding of gender as something people do, as opposed to something people are, in the publication of their article titled “Doing Gender” in 1987. Although not the first to identify gender as a process (this had been suggested in other academic fields prior to 1987), their article solidified researchers’ understanding of gender as a social process and emphasized the importance of this understanding in organizational research. Shortly after publication of this important work, Patricia Yancey Martin further problematized the notion of “doing gender” and used the term *gendering* in an unconventional way throughout much of her work in the 1990s. Her work is frequently cited and well regarded.

At the same time that the work noted above was being produced, Joan Acker and her colleagues were working on the conceptualization of social structures (organizations included) as gendered. In “Differential Recruitment and Control: The Sex Structuring of Organizations,” Joan Acker and Donald R. Van Houten note the apparent genderedness of organizational structures and positions. Within this piece, Acker and Van Houten note the existence of gendering processes but do not refer to them as such. It is not until her solo work of 1998 that Acker uses the language of gendered processes. In *Class, Gender and the Relations of Distribution*, Acker contends that the organization of labor and production are gendered and that this genderedness is a result of gendered processes. It is here that the notion of gendered processes first comes to the forefront in Acker’s work. It is also where she provides a definition of *gendered* and introduces her notion of *gendering* as the processes within organizations that are responsible for the creation of gendered organizational phenomenon.

One of Acker’s most influential and often-cited works appears in 1990 in an issue of *Gender & Society*. Titled “Hierarchies, Jobs, Bodies: A Theory of Gendered Organizations,” this is an attempt at a systematic theory of gender and organizations and provides a framework of gendering processes. According to Joan Acker, there are five types of gendering processes in organizations. They include gendering practices/structures, gendering cultures, gendering interactions, internal gender constructions, and gendering organizational logic (or the gendered substructure of the organization).

Several other organizational researchers have endeavored to identify and describe these gendering processes, particularly those within the organization culture paradigm. Due to these contributions, as well as those noted above, significant progress has been made in terms of better understanding of how gendering occurs. For example, it has been widely recognized that masculine cultures, characterized by masculine slogans, symbols, and metaphors, play a prominent role in the gendering of some organizations. The notion of “guerilla marketing” provides a good example. Multiple organizations have adopted this concept in an attempt to “rally the troops” and to encourage aggressive marketing. In addition, the concept is taught in many business schools. The use of this metaphor

can be seen as gendering the process of marketing and the tactics employed. This may silence those wishing to adopt less masculine tactics and may privilege those possessing predominantly male characteristics.

Another theory of how gendering occurs suggests that individuals doing gender in organizations are responsible for the creation and maintenance of gendered organizations, particularly, but not exclusively, those in power positions. This line of thinking suggests that everyday interactions, understandings, and internal gender constructions serve to reify already gendered notions or logics within the organizations and, in effect, are responsible for the gendering of the organization. Examples of this include men asking women to serve coffee, women adopting nurturing management styles, and men and women adopting conversation styles that privilege men while essentially silencing women.

#### **Application: Gendering at Pan American Airways**

Acker’s work provides one of the most compelling and comprehensive frameworks through which to study the gendering of organizations. Her work provides a possible heuristic for the examination of gendered organizations that could potentially build on the success of the culture paradigm and other works aimed at understanding the gendering of organizations. In her 1990 article, “Hierarchies, Jobs, Bodies: A Theory of Gendered Organizations,” Acker identifies five general categories of processes that lead to gendered organizations. The following provides a brief overview of these gendering processes.

#### ***Gendering Practices/Structures***

The first set of processes is described as the production of gender divisions. These can be seen in the gendered patterning of jobs, wages, and hierarchies. An archival study of Pan American Airways (PAA) conducted by Kelly Dye and Albert Mills concluded that these could easily be observed through the identification of rules and roles that indicated that some positions were more appropriate for men while others were more appropriate for women, or promoted the advancement of one group while hindering the other. This was captured through formal

and informal job requirements, photographs of employee groups, and internal memos.

### *Gendering Cultures*

Acker's second set of processes includes the creation of symbols and images that serve to create lines of privilege and power in terms of sex and gender. The effects of these can be analyzed on both a societal and an organizational level. For example, organizational symbols and slogans emphasizing strength, speed, or power help to create an environment that values characteristics traditionally associated with maleness. At PAA, men were praised for being strong and growing large mustaches and were always referred to as the "head of the household," while women were referred to as "gals" or "cuties." Similarly, pop-culture icons help to shape societal understandings of what it means to be male or female.

### *Gendering Interactions*

Acker's third set of processes describes the interactions between individuals that enact dominance and subordination and/or silence or privilege one group over another. Moving to a more intimate level of analysis, this category emphasizes the importance of individual-level interaction as a gendering instrument. The aforementioned study of PAA endeavored to identify these processes by looking at how men and men, women and women, and men and women interacted. Although not witness to actual conversations per se, it was possible to identify how interactions were "supposed to look," as sanctioned by PAA executives, employee contributors to the internal newspapers, article writers, and editors. In this instance, cartoons were often valuable sources as they described several types of relationships; that of the boss and the secretary, the boss and the mistress, female coworkers, and the relationship between male and female coworkers.

### *Internal Gender Constructions*

The fourth set of processes encompasses the internal mental work of individuals as they make sense of what it means to be a man or a woman within their organization, and the behaviors

deemed appropriate as a function of their sex. The task of identifying such processes becomes more difficult as there is a need to "see inside" the thoughts and feelings of individuals as they construct their gender identities. Participant observation, analysis of diaries, and ongoing interviews may be able to capture pieces of this process set. In the case of the PAA study, reliance on the understanding that individual identities are constructed through discourse was essential, as was the understanding that discourse analysis provides a way to unpack this construction. Discourse analysis of archival materials from PAA was used to examine how men and women wrote about each other and themselves, and what the discourses suggested would be appropriate ways for men and women to construct their identities, were studied.

### *Gendering Organizational Logic/Gendering Substructure*

The final set of processes is centered on organizational logic and the gendered substructures that are reproduced in daily organizational activities and the writings of organizational theorists. Seen as fundamental, ongoing processes that encompass and influence the other four processes, these processes require study at an entirely different level of abstraction (i.e., the study of the logic inherent in and affected by organizations and the people within them). The PAA study concluded that a study of dominant and competing discourses within the organization, set against larger societal discourses, might help to better understand the underlying logics or structures that are responsible for gendering the organization.

### **Critical Summary**

As stated previously, organizational researchers seem to agree that organizations are gendered, and progress has been made in terms of learning much about processes that may be responsible for the gendering. However, there is not agreement among scholars as to which processes are most important for the study of gendered organizations and the subsequent reduction or elimination of such gendering. Despite the disagreement among scholars, much progress has been made in terms of understanding gender as an ongoing social process and

the subsequent effects these processes have on the gendering of organizations.

for case studies that seek to understand how popular knowledge has been repressed, or for those that strive to determine how struggle and conflict have resulted in the exclusion of particular parts of history. There is, however, a danger that once revealed, repressed knowledge and history can be adopted back into the dominant discourse. Genealogy does not propose to replace one truth with an even better truth but to show the contingent, accidental, and precarious nature of the present and of history.

### Conceptual Overview and Discussion

Genealogy is associated most closely with the work of Michel Foucault and his extension of Friedrich Nietzsche's concept of an "excess of history." This is a state where the contingencies, contexts, and alternative explanations for the present are viewed as inconvenient extras and thus are forgotten. As a counterweight to this process of forgetting, genealogy uncovers the silences, accidents, and intersections that have resulted in a taken-for-granted approach to knowledge. In contrast to historiography's question of "what is our past?" genealogy asks "what is our present?" To answer this question, genealogy departs from traditional histories in two significant ways. First, genealogy does not portray the present as the inevitable outcome of a select series of past events. Through two of its methodological components known as descent and emergence, it uncovers the contingent and indifferent nature of history. A second feature, problematization, drives the genealogical project by seeking to understand how the present has come to be defined and understood in its current form.

### *Descent and Emergence*

For the genealogist, the present emerged and descended from a series of discontinuities that could have, under different circumstances and in a different context, produced something quite different. In genealogy, the utilization of history to explain the past is eliminated in favor of a contingent and contextual approach. This requires a suspension of belief in current views of knowledge acquisition and the development of a deep suspicion about any natural and self-evident truths

---

## GENEALOGY

---

Genealogy is a method that defamiliarizes the taken for granted by rejecting linear histories of knowledge that emerge from a single origin. Genealogy attempts to uncover the history that has been hidden in the construction of a logical narrative of how the past occurred through an examination of the descent, emergence, and trajectory of events. It is an appropriate methodology

about the subjects and objects of interest. Contrasting genealogy with history helps explain how it works in practical terms: A history that explains the past further entrenches current conditions, whereas a history of the present seeks to understand how the present has come to be organized. Historical events are linked together into a rational, linear progression from an origin toward the current order of things, whereas the genealogist seeks to demonstrate that the present is not the product of an inevitable series of events. Genealogy removes the comfort of the present as a natural and better place than the past so that the present may seem equally as contingent. In practical terms, the method of genealogy involves an examination of the descent and emergence of various historical trajectories. *Descent* deconstructs the taken-for-granted nature of the present, enabling the genealogist to identify the precontexts of the taken for granted. It investigates and uncovers contingencies, accidents, and mistakes to relate a story of knowledge production that does not take a linear, inevitable path. While descent disturbs the given, *emergence* points out interactions in the details of descent that result in what appears to be a given. In other words, the present has struggled to emerge through multiple contingencies and accidents, without goals or progress, as the current resting point rather than a terminus.

### *Problematization*

The problematization of the present is at the core of genealogy. *Problematization* does not create an object or explain something that already exists. Rather, it enables the products of discourse (institutions, propositions, or rules) to be seen for what they are: the sites of claims to truth, and ways of governing the behavior of others. Problematization thus reframes the conduct of historical analysis to understand how it has transpired that the present has come to be accepted as inevitable or natural. It is not an excuse to rewrite history, however, or to make factual errors in relating history. One must also be cautious to avoid framing the past in terms of current understanding: Genealogy does not view the present as static, and so today's problems and concerns will be different in the future. Further, there is no need to search back to the beginning of recorded history in

problematizing the present as problematizations emerge at a specific point in time. Problematizations do not repeat themselves, but occur as background noise in a continuity of other events and emergences. As they span large historical periods, the method of studying problematizations must rely on primary and secondary sources. Thus, it will often involve accessing archival material for historical documents as well as secondary sources from historians. It should be borne in mind that while genealogy does contrast sharply with traditional historiography, it does not outright reject coopting existing histories to serve its own ends.

Genealogy is archival in its method in two senses of the word. First, it is archival in that the genealogist works within physical archives and with primary and secondary source texts. But the archive also refers more broadly to the canon of statements that emerge and persist within a society at any given period. In the former sense, the archival nature of genealogy implies that existing methods for accessing, searching, and documenting archival research can be used. This includes the understanding of archival sedimentation: that materials are collected, kept, and then deposited into archives in an unsystematic manner from which will emerge various different layers of documentation. Existing histories can be used where there is limited completeness of the archival record and thus can provide welcome bridges between long periods where there are no primary sources. This reuse of the grand narratives created by historians that point to a continuous and unfolding historical picture are useful for genealogy in that they serve to contrast the accidents and contingencies displayed in a genealogical approach.

### **Application**

Foucault did not leave a methodological text from which people could understand how to utilize genealogy. However, the wealth of empirical and theoretical scholarship on genealogy provides a more than adequate road map. Perhaps the ideal starting point for seeing genealogical method in practice is Foucault's *Discipline and Punish*. While Foucault's work does not adopt a case study approach, it should be read by anyone interested in undertaking a genealogical analysis. Fortunately, there do exist exemplary pieces of case study

research utilizing genealogy. One of these is by David Knights, Fergus Murray, and Hugh Willmott, who looked at the case of the creation of an electronic trading network known by the pseudonym Switchco for the life insurance sector in the United Kingdom. The story of the case follows the establishment of the Switchco network, and in particular, the discursive construction of the knowledge workers who make up the individual insurance firms that are part of the network.

Elements of the genealogical method are evident throughout the case methodology. Descent is found through the authors' deliberate avoidance of a linear history of the creation of the Switchco network. Instead they choose to illustrate the ongoing and dynamic fashion in which the knowledge workers recreated their involvement in the project. The authors illustrate the competing interests, contingencies, and accidents that form the descent of the Switchco network. Further, by pointing out the details in the interaction of the descent, they show how the object referred to as knowledge work, as embodied by the network, emerges from these multiple, divergent, and contingent circumstances. The case also demonstrates the problematization of knowledge work. The authors attempt to show through the genealogy of Switchco that knowledge work is not simply a job categorization; rather, it indicates changes in work organization as a result of greater influence of information as a resource.

In another illustrative case, Kate Kearins and Keith Hooper examine the role of accounting in the acquisition of land from the Maoris in the 19th century. The case is doubly useful as the authors provide an extensive description of their use of genealogical method throughout the case. In the late 19th century, Europeans began to acquire large portions of land from Maoris in New Zealand. The authors contend that the historiography of land acquisition relates a story of Maori innocence and European dirty tactics. However, Kearins and Hooper reject this linear approach to colonial history and instead utilize genealogy to examine the descent of land acquisition. The physical archive for the genealogy consisted of the correspondence between one of the Europeans, Sir Donald MacLean, and his accountant, together with additional material from the New Zealand government archives. The genealogy points to the emergence of accounting practices in determining

how the Maori came to accept and participate in the loss of their land. Therefore, the authors problematize the role of accountancy in mediating the acquisition of Maori land.

### Critical Summary

There are strengths and weaknesses in employing genealogy as a case study methodology. As good case studies thrive on the availability of rich detail, genealogy responds well as it functions on a detailed understanding of history. Genealogy provides alternative explanations within a particular case by problematizing the objects of discourse and through the use of the methodological tools of descent and emergence. While the strength of genealogy is its ability to move beyond linear explanations of how the past resulted in the present, the method of achieving that strength is a drawback for case study research. Ideally, genealogy relies on painstaking and laborious archival research that often extends beyond the boundary of a single organization or event. For the case study researcher, the task becomes a judicious choice of limiting the time frame studied for a particular problematization so that it becomes manageable. Another challenge is to understand and correctly apply the methodology. For this, one has to rely on secondary interpretations of Foucault's work as well as examples of the methodology in practice as presented in the application section of this entry.

## GENERALIZABILITY

---

Drawing on the etymology of this term, *generalizability* refers to the ability of extending the validity of one's case study conclusions to other cases of the kind. More commonly, generalizability refers to a broad concern that arises when researchers have studied one or a few cases and ask: Do our findings, our insights, or our descriptions apply to other cases? Generalizability is thus more or less synonymous with the notion of external validity.

Many strategies have been proposed to support claims for generalizability. In fact, their legitimacy depends on the ontological assumption underpinning the research at hand, whether it be positivistic, realist, constructivist, or postmodern. While none of the proposed strategies are fully convincing, some researchers devote much energy to ensuring generalizability; others propose the reader is responsible for applying case study results to other case studies; and still others shrug off the question of generalizability, asserting its irrelevance for case study research. The question of the relevance of generalizability also highly depends on the reason researchers are interested in the case: Do they want to know more about the specific case itself, are they aiming at some general "truth," or do they want to dip into a specific case to foster an understanding of the complexity of given situations?

### Conceptual Overview and Discussion

The notion of generalizability has long been a concern for survey researchers. When, for matters of feasibility, they need to confine the study to a sample, they want some assurance that the conclusions remain valid for the entire population. Many statistical tests have been designed to certify the possibility of the generalization of their results. But because a precondition for ensuring generalizability is a large sample size, which is unlikely when undertaking case study research, these statistical tests are not always feasible for case study research.

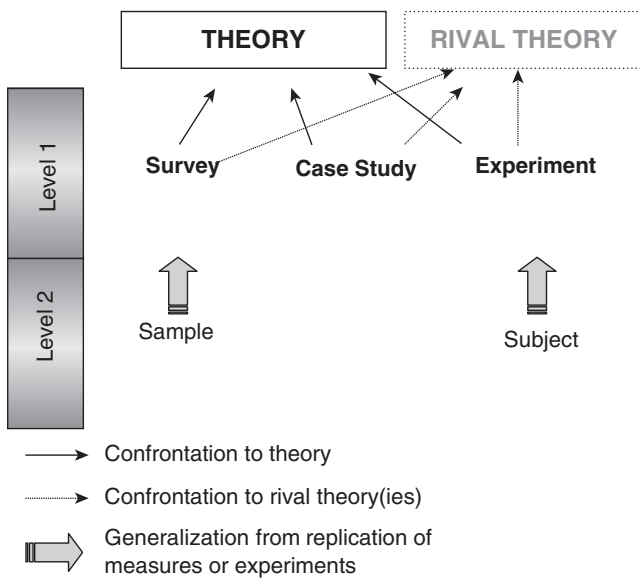

From a positivist approach, the researcher looks for correlations between phenomena or variables. The more general are the findings, the more valuable

is the research. In this endeavor, a case study can represent only a very small sample, exploring a new context, giving the "flesh" and the circumstances for a better interpretation of the correlation. But in order to ensure the generalizability of case study findings, further studies that rely on the same logics as survey research are required. A case study provides the exploratory phase of research upon which more extensive quantitative research can be based.

Most of the various strategies in case study research that act to ensure generalizability rest on realist ontological assumptions. This means that a reality is presupposed as existing underneath and underpinning the apparent world. A case study is one of the best of manners in which to access this underlying reality. Once this reality has been rendered visible and explainable thanks to one case study, the researcher seeks to verify the existence of that reality in other cases to assess the extent to which the findings are generalizable to a specified population. This process has been undertaken in research informed by realist ontological assumptions, including that of Barney Glaser and Anselm Strauss, Robert Yin, and Haridimos Tsoukas.

From a constructivist approach, the researcher approaches his or her research on a given phenomenon with the assumption that the phenomenon as such exists only through his or her mental appreciation of it. Thus, from this approach, the researcher does not infer as to the possibility of generalizability. The reader must, however, assess whether the proposed insight may help him or her understand other cases of interest. This is one reason that Yvonna Lincoln and Egon Guba have proposed replacing the concern for generalizability with that of transferability. Robert Stake's as well as Robert Donmoyer's strategies have followed in the approach set out by Lincoln and Guba.

From a postmodern approach, the very existence of a "case" is put into question. The case is seen as a particular framing of the world that has no superiority over others, and that is often phallo-, ethno-, or logocentric. The case study becomes an opportunity to uncover the way in which we frame problems, representations, and power relations that a society and academic sphere impose. It enables the possibility of voicing and recognizing the silenced and unconsidered, and of addressing from a specific viewpoint generic problems of our society and our being-in-the-world.

**Figure 1** Statistical and analytic generalization

Source: Yin (2002).

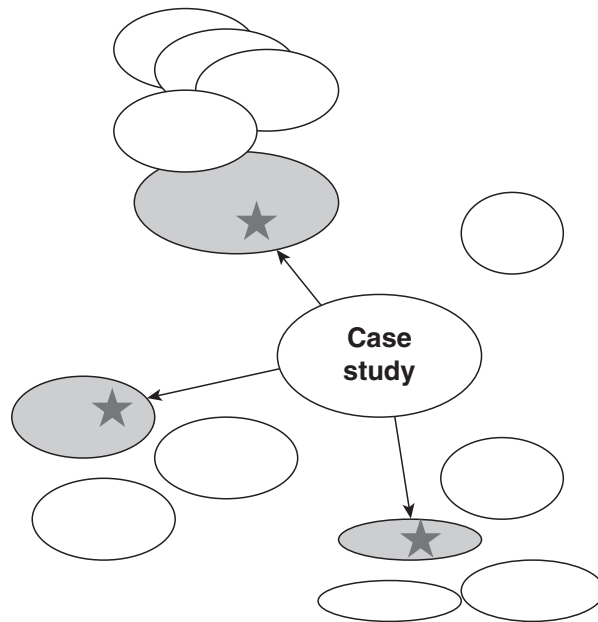

Notes: Two levels of generalization, according to Yin. Analytic generalization refers to level 1, whereas statistical generalization is on level 2.

The question of generalizability is here downplayed in favor of the question of exemplarity and justice.

### Application

As we have seen, there are several perspectives on generalizability that each offers a different strategy for claiming generalizability. Let's see the various rationales underlying these possible strategies. Barney Glaser and Anselm Strauss, in their *Discovery of Grounded Theory*, have drawn a distinction between statistical and analytic generalization. On the one hand, statistical generalization infers from a sample of the characteristics of the whole population, requiring an interpretive second step from these characteristics to theory. On the other hand, an analytic generalization is a direct confrontation of the case study with an established theory (see the representation provided by Yin in Figure 1).

Drawing on the preceding distinction, Yin proposes that the researcher replicate his or her case study to a small number of cases where the conclusions are understood to fit and not to fit (e.g., one

**Figure 2** Generalization in grounded theory

Source: Glaser & Strauss (1967).

Notes: In the constant comparative method, conclusions are tested in a case of a near population in order to expand generalizability.

should study three or four cases where the conclusions can be seen to fit and not to fit). In the instance where the researcher finds cases in which the theory does not fit, it is up to the researcher to provide a theoretical explanation for the lack of reproducibility of the theory. This is done in hopes of rendering the conclusions more robust. At the end of the replication process, the conclusions can be said to be generalizable. If other researchers show the lack of application of the findings to other cases (where according to the theory it should), it is up to the previous researcher to provide an explanation that supports his or her observations as to why the conclusions were applicable. Through this progressive process, the generalizability of the results of one case study to other cases is rendered more precise.

Another strategy for increasing generalizability is provided by Barney Glaser and Anselm Strauss. According to them, generalizability is to grow in "circles" (see Figure 2). The conclusions of one case study are tested in a slightly different setting, and then step by step to a larger circle of settings. For example, one could test the conclusions of a

given case in different federal departments of a federal agency, followed by different departments in different agencies, different regions of a nation, and, further to different nations. If the findings or the concepts are still valid after this process, it may be safe to assume the conclusions of a given case study are generalizable to a wider population. However, if the conclusions are not valid, then the conclusions must be amended so that they can apply to both the previous cases and the new environment. In the end, the concept or the theory will no longer be context specific, and the researcher ends up with a “substantive” (general) theory.

Haridimos Tsoukas proposes a more direct generalization strategy that is based on critical realism. According to him, the case study offers the opportunity to uncover the causal powers and generative mechanisms that reality imposes on the actual world we experience. Researchers seek out universal causal laws and necessary ways of acting. If the researcher has fostered a deep enough understanding of the reality of the situation at hand, then the said causal powers and generative mechanisms, because they represent the underlying reality, have a high degree of generalizability. If the generative mechanisms were not observed, it would be the researcher’s responsibility either to explain the obstruction or amend the theory. It must be noted that for a researcher to adopt this method of generalization, the researcher must be sympathetic to critical realist ontological assumptions.

Lincoln and Guba have objected to realist ontological assumptions. Instead, they impose upon the reader the charge of ensuring the generalization of the theory of question. Lincoln and Guba propose the image of a hologram in which each part contains all the features of the whole. Using this metaphor, they state that the case study contains all the features of the whole. That means that if the case is akin to a microcosm of the general, then what was observed and theorized in the case study has a certain degree of generalizability. Of course, the degree of generalizability will not be valid in every situation. If a reader wonders whether the conclusions apply to another situation, he or she is in charge of assessing whether or not this new situation pertains to the same whole of which the first case study is a hologramic piece. The reader would then not generalize the findings

to the new setting, but rather transfer them to this new setting to test their applicability.

Stake makes the case for a naturalistic generalization. Stake notes that, while studying the case, researchers gain a subjective understanding by recognizing their experience in the natural world. They may have the skill to help the reader in sensing the subjective understanding in question. These experiences are general by nature, even though they again may not be present in every situation. The value of the case study and its generalizability is confirmed when, if faced with a similar situation, the reader is able to recognize the resemblance of experience and is able to put it into practice. With a reversed logic, Robert Donmoyer advocates that the reading of a case study may make us live rather unfamiliar situations. Thus, we gain experiences that we could not have accessed otherwise. This knowledge will possibly be used, that is, transferred (generalized) to other situations. In these latter approaches, generalizability is not asserted or proved, but proposed as a possibility that the reader may find useful.

In a more postmodern strategy Jean-Luc Moriceau remarks that what will happen in other cases is not the same features, but a mix of sameness and difference. Repetition, a concept borrowed from Gilles Deleuze’s *Difference and Repetition*, could be a more useful concept than generalization for thinking of external validity for case studies. Taking the singular case of the Enron collapse as an example, generalization would either mean that the same unethical behaviors would reoccur identically (what the Sarbanes-Oxley Act of 2002 was meant to prevent) or suggest that these are necessarily due to the inner structure of capitalism. Repetition would suggest that similar misdeeds will reoccur, but be full of dissimilar features. Problems are repeated, but new ways of dealing with them are constantly reinvented. Such a case study is rather meant to show problematics, raise questions, or describe possibilities than to bring a knowledge that would be valid, identically, in other settings.

### Critical Summary

The notion of generalizability as it pertains to case study research is sometimes scorned by researchers who seek to establish correlations between large

numbers of instances. But this does not mean that a case study's external validity is weak. Rather, other generalization strategies have to be put forward. Yet, before generalizability can be sought, researchers must acknowledge the ontological assumptions of their research and find a method of generalization that is consistent with their assumptions.

However, one can also wonder whether the aim for case study research should be results in which generalizability is sought. First, it is questioned whether the aim for case study research be the generation of rich knowledge of a given phenomenon or less rich but generalizable knowledge of that phenomenon. Second, the case study method may seek other kinds of insights, a nonexhaustive list of which would include uncovering unjust relations or situations, the proposition of new ways of looking at situations, the better understanding of other beings in the world, or the power relations that are implied in a specific way of doing research.

## GENERICIZATION

---

*Genericization* is the process of forming generic knowledge through providing a higher conceptual-level generalization of local substantive knowledge generated in case study research. Genericization strives to transcend the singularities of local substantive knowledge regarding a certain phenomenon in order to discover metarelations that this local knowledge instantiates. In other words, genericization aims to encapsulate local knowledge in synthetic generic statements that are expressed more often in natural language than in mathematical terms. Generic knowledge is particularly valuable in organization studies when it provides stimulating insights into recurrent concerns in organization practice that are not yet satisfactorily illuminated by knowledge already published in academic or professional journals. It is particularly valuable when it contributes to filling theoretical gaps relative to enduring practical concerns.

### Conceptual Overview and Discussion

Before explaining genericization, the notion of generic knowledge has to be characterized more precisely. It extends the notion of generic proposition developed by the pragmatist philosopher John Dewey. Generic knowledge expresses knowledge about kinds of things and processes rather than about particular instances or about statistical regularities. The so-called generic drugs in the medical field offer a good metaphor for grasping the meaning of the term *generic* in the phrase *generic knowledge*. A generic drug's labeling, namely its chemical name, captures the specific core of a drug that can be found under various brand names.

The notion of generic knowledge did not diffuse rapidly in the social sciences. This may be because it poses a number of epistemic questions, such as: How do we acquire knowledge about a certain kind of thing or process if we have a limited number of examples, or have experienced only a single instance of the thing or process in question?

Robert Prus used the term in 1987 in the field of organization studies to equate generic social processes to the dynamic features of association that transcend the content or substantive features of group life. One form of negotiation that takes

place in a group, for example, can be envisioned as an instance of a generic process, while the items being bargained for denote the content mediated through this social form.

In the mid-1990s, the notion of generic knowledge was taken up by researchers from various cognitive sciences who were curious to investigate pending epistemic questions. For instance, Sandeep Prasada underscored that generic knowledge involves knowledge of properties that are considered essential for being a particular kind of thing, for instance, dogs have four legs. At the same time, generic knowledge is not rendered invalid by the existence of what seem to be counterexamples; for example, the fact that there exist some dogs that have only three legs does not render the above statement false. Besides, when a certain kind of thing has certain properties, it is considered to be by virtue of being that thing, not by virtue of any hidden underlying mechanism.

The notion of generic knowledge does not imply making a positivist or realist ontological assumption of the existence of a unique real world governed by law-like underlying mechanisms. Rather, it is consistent with constructivist epistemological paradigms such as Ernst von Glasersfeld's radical constructivism, as well as with interpretivist methodological paradigms, on which case study research often relies.

### Genericization and the Use of Generic Knowledge About Organizations

Generic knowledge can take on the form of meta-models such as Michael Porter's five forces model, frameworks and configurations such as Henry Mintzberg's organizational configurations, as well as patterns such as Norwood Hanson's patterns of discovery. Patterns are built from regularities identified in the functioning or evolution of the kind of organizational phenomenon studied. In constructivist epistemological paradigms, these regularities are not viewed as resulting from permanent underlying mechanisms or law-like causal relationships. They are considered as perceived temporary stable patterns that, in organization studies, stem, for instance, from recurrent behaviors associated with organizations' formal and informal systems.

Genericization is a process for generalizing knowledge. According to Dewey, there are only two kinds

of general propositions, namely universal propositions and generic propositions. The elaboration of universal propositions taking the form of acontextual atemporal law-like relationships rests on an assumption, usually implicit, of existence and knowability of such underlying laws. The elaboration of universal propositions is usually considered inappropriate in constructivist epistemological paradigms. On the contrary, genericization appears as an adequate way to conceive of generalization in research carried out in these epistemological paradigms.

Genericization can be performed in an inductive way via the systematic study of multiple comparison groups and substantive theories as in the generation of what Barney Glaser and Anselm Strauss called a "formal grounded theory." Unlike the phrase *generic knowledge*, *formal grounded theory* has specific connotations that imply the following: a theory built by logical deduction from a priori assumptions and, most often, expressed in mathematical formalism. This connotation is limiting in that it does not correspond with what the authors initially advocated.

Generally, genericization relies on iterations and back-and-forth connections of the information gathered in the case study, local knowledge developed, knowledge available in literature, conjectures made by the researcher, and going back to the field to collect further information and back to academic literature to clarify emerging notions. Genericization is not a strictly inductive process. Abduction plays an essential role in this process.

Generic knowledge is characterized by the fact that, in order to be used in a specific setting, it needs to be contextualized and hence interpreted according to the idiosyncratic circumstances of the setting. Contextualization involves a complex thought process implying reflection and reinterpretation. This might lead to meanings that are quite different across local contexts and even induce modifications of the generic knowledge's initial meaning. Hence, contextualization cannot be viewed as giving values to predefined variables or parameters as in traditional contingency-based research. Moreover, if contextualization can be facilitated by researchers, it cannot be accomplished solely by them, even those acquainted with the specific practice context. In order to be put to use, generic knowledge demands local sensemaking and self-design in the practice unit.

This implies that generic knowledge cannot be tested and validated in an epistemological positivist sense. Alternatively, only its expression in specific contexts—hence its contextualization—can be tested. Since contextualization implies reinterpretation and reconstruction of the meaning of that knowledge according to the specific circumstances of the setting considered, the hypotheses to be tested would be contingent on the individuals who were active in the contextualization of that knowledge in the various settings. This makes statistical testing subjective and hence nonconclusive. Instead of *ex post facto* validation, the legitimization of generic knowledge is performed jointly with its elaboration. What this implies is that genericization and legitimization of the elaborated generic knowledge are carried out as two inseparable and simultaneous processes.

Generic knowledge can be put to the test of practical experience through attempts to activate it in settings where researchers consider it may be relevant. In this instance, what is tested is whether the practitioners who are active in the contextualization of that knowledge in their practice unit find it useful for sparking reflective dialogue, gaining pertinent insights on the problematic situation considered, and/or stimulating creative action.

The legitimization of generic knowledge may also be enhanced by its communication in professional meetings and/or in professional journals to practitioners. The complementary legitimization would come from the practitioners' acknowledgment of the relevance of this knowledge for reflecting on their practical concerns and finding solutions. The feedback that researchers obtain from the audience or the journals' editors and readers may be particularly valuable for further advancing the conceptualization of that knowledge.

### Critical Summary

Statistical generalization of local knowledge seeks to extend knowledge developed in certain settings to other, slightly different settings. It does not aspire to develop novel insights from local knowledge elaborated in a particular research project. Unlike statistical generalization, genericization aims to suggest plausible connections and relationships among notions capturing fundamental aspects of the local knowledge that have not been published in the academic literature yet.

## GOING NATIVE

---

*Going native* is an experiential field work method in which the researcher seeks to see the social universe in the same way the people being studied do. This form of data collection takes the notion of participant observation beyond its usual limits, as researchers are encouraged to cross a line of objectivity to experience the world in the same terms as the people being studied in order to understand contemporary societies in their own terms. This method has both advantages and disadvantages and raises issues in larger debates about the

possibility of objectivity and the role of the researcher.

### Conceptual Overview and Discussion

The term *going native* is indicative of the 1900 colonial imaginary in which Western science constructed the non-Western world as being inhabited by the objects of science, or “natives.” Colonizers were conceived as being at the top of the human evolutionary ladder, but also as being at risk of being corrupted and falling from their moral pinnacle if they adopted non-Western knowledge systems, values, and beliefs.

In anthropology, this term is usually attributed to Bronislaw Malinowski, who formulated ethnographic field work as a paradigm and reflected on the relationship between researcher and the object of study. Based on his research experience in New Guinea, Malinowski suggested that in order to be able to grasp peoples’ perspectives, their relationship to life, and their vision of the world, researchers should go native by taking part in peoples’ social lives.

Since then, ethnographic field work has become a research method to explore communities and their patterns of social interaction, cultural meanings, institutional infrastructure, and process of change and conflict. This method is inductive and has been used for discovering issues and questions researchers were not previously aware of. By becoming participant insiders, as opposed to being mere observers, researchers can be able to feel, think, and even behave as insiders or natives. Accordingly, by “being there,” the researcher has access to events, behavior, and contextual dynamics that enrich the experiential method in which the researcher becomes the instrument of data collection.

Since the research is conducted in the chaos of natural settings, the going-native field work method emphasizes the need to live in a native village for an extended period of time, sometimes years, for constant observation, and for learning the local language, learning exact recording, and separating inference from data. Arguably, collecting a broad range of concrete data such as observed incidences, genealogies, maps, and diagrams showing ownership of land gradually provides the resources for understanding the organization of the society being studied, its custom-

ary law and practices, and its culture. Thus, ethnographic data are not gathered only through conversations, observations, rituals, and interviews, but also through personal documents such as research journals, letters to colleagues and friends, and other forms of documentation recording researchers’ thoughts and impressions. Going native and colonial fascination with non-Western cultures have led Western scholars to impersonate the sociohistorical role of studied societies through acts of cultural appropriation. This practice has exposed the relationship between colonialism and the production of knowledge and culture.

The method of going native has been challenged for its lack of scientific objectivity and claims of attaining knowledge usually reserved for community insiders. In coming to terms with the pitfall of observing and participating in a foreign community, many contemporary social researchers have become self-aware of their relationships with the communities they study, but although interest in these ethical dilemmas is increasing, not all social scientists are equally concerned.

The going-native method has been severely challenged for different reasons. One of the most serious methodological challenges to this approach focuses on objectivity issues and so-called observer bias. An observer/participant who is part of the context being observed has lost objective detachment and undermined the reliability and validity of observational data. In becoming too involved with people, the researcher changes and loses perspective and objectivity by taking on the perception of the people studied.

Yvonna Lincoln and Egon Guba, who have written extensively on qualitative methodology, argue that while prolonged engagement with people is necessary to build trust and rapport, researchers need to maintain a balance between their “insider” and “outsider” statuses. As well, James Clifford challenged traditional ethnography for assuming that field work is a ground of knowledge and that it has to be conducted in remote non-Western communities. He also questioned the ethnographer’s ability to know “others.”

The relationship between observation and participation has been central to ethnography since Malinowski famously encouraged researchers to move from the verandah to the community. In

recent years, the going-native approach has also become the focus of ethical research dilemmas. From this perspective, going native not only compromises the validity of the data but also the participants' well-being. Harold Lloyd Goodall Jr., who has written about the "new ethnography," argues that because, historically, the going native field work method has lacked objectivity, researchers must remember that both subjectivity and respect for participants are two important dimensions of the research process.

Therefore, self-reflection about field relations has shifted the focus from the native's point of view to the researcher's point of view. The practice of building and sustaining relations with people has provoked reflection on balance, the quality of research, and the well-being of participants. Balance refers to the researchers' obligation to tell the truth to the people being observed and to others. The quality of the research should be maintained throughout the entire research process, including the design, implementation, and reporting of results. Researchers also must avoid compromising the participants' well-being at all stages of the research. All these elements are based on ethical assumptions rooted in reformulated positivist and postpositivist epistemologies suggesting a different approach to conducting ethnographic field work.

### Application

Ethnographic field work is frequently used to provide a descriptive study of human societies. Many anthropologists consider ethnography the essence of the discipline, although other disciplines such as sociology, psychology, and economics have used field work as a way of understanding the specificities of people's daily lives, institutions, consumers' behaviors, and the acceptance of new products or services. However, contemporary ethnography has moved away from the going-native approach and now focuses on central guiding questions connecting the local field site with larger questions about how culture works.

While the social and political dimensions of ethnographic research have been evolving over time, researchers have been increasingly encouraged to make their studies more responsive to community concerns. These concerns can be addressed by emphasizing a greater collaboration with partici-

pants and by making the relationship between researchers and participants more explicit in the research process. Similarly, critical approaches aim at not only framing questions but also promoting action. Critical ethnography goes beyond the description of culture by challenging power relations and promoting people's emancipation. Approaching research from the above perspectives requires the researcher to identify the nature of the researcher-participant relationship in a way that is committed to both the quality of the research and the integrity of the participants. The connection between researcher and participant yields increased self-disclosure from participants and increased understanding of the context on the part of the researcher.

Some of the alternatives for minimizing the problems associated with going native include (a) maintaining distance between researchers and the people studied, (b) setting up feedback mechanisms or asking people to read what researchers write, (c) setting up a structure for communication between researchers and participants, and (d) setting up regular meetings with participants. More important, determining the researcher's stance in advance of carrying out the research helps to guide decisions as ethical dilemmas arise.

### Critical Summary

Going native is a experiential field work method that takes the notion of "participant observation" beyond its limits by encouraging researchers to cross the dividing line of objectivity, the line between scientists and communities. The expression *going native* is a representation of a colonial imaginary, for it represents a commitment to living and seeing the social world from the viewpoint of native peoples. In social research, to go native is to loose commitment to scientific truth, detachment, and rationality.

## GOVERNMENTALITY

---

Governmentality (*gouvernementalité*) is a notion that was introduced by French philosopher Michel Foucault in the 1970s and was later elaborated upon by a number of social theorists, especially in the English-speaking academic world. Governmentality studies examine the art of governing populations and directing human behavior at a distance, which typically also involves the self-government of people. Governmentality perspectives are applicable through case studies across a wide range of social and behavioral sciences, including education, management, political science, public administration, and the human services.

### Conceptual Overview and Discussion

Understanding governmentality requires understanding Foucault's critique of conventional conceptions of power. In his alternative conceptualization, power is dispersed in society, related to knowledge, and productive rather than repressive. This means that government is understood to rely at least partly on the production of "truths" about different activities and institutions in society, and that these truths give people subject positions to inhabit, in ways that ideally are productive for themselves and society.

What the term *governmentality* refers to can be interpreted as a combination of *government* and, alternatively, *mentality* or *rationality*. Both interpretations are valid, as governmentality should be understood as a certain mentality of government that is guided by specific rationalities rather than explicit ideologies. A governmentality perspective in turn focuses on how certain governmental rationalities are mobilized in order to enable the regulation of people's conducts. It typically aims to understand and describe the art of government deployed in contemporary societies in order to direct human behavior and manage populations at a distance. The reason that emphasis is put on populations relates to a biopolitical understanding

of the population as a sort of natural collectivity characterized by specific regularities and trends that government needs to create knowledge about in order to be able to govern.

Governmentality analyses have been applied mainly to the political rationality of liberalism, which can be understood as an art of governing rather than a doctrine. Liberalism differs from other governmental rationalities notably because it takes into account the need for people not to feel governed: It is meant to govern free people. Liberalism also introduces a distinction between state and society, explicitly aiming at the better good for the latter rather than the former. For its assessment of the societal better good, liberal governmental rationality mainly relies on political economy, which is considered the appropriate knowledge base for regulating the population as a whole. Liberal political programs are in turn informed by this type of knowledge, the views of experts who participate in its production, and the many indicators it produces, which makes reality intelligible in such a way that political action can be seen to influence it directly.

The liberal problematic of governing free people tends to be central in governmentality studies. In liberal societies, the technologies of domination, relying for instance on disciplinary power, cannot be exclusively relied upon. In order for free people to conduct themselves in ways that are desirable for society as a whole, these conducts also need to be personally desirable. For this purpose, appropriate technologies of the self, offering ways for people to fulfill themselves while being somehow productive for society, need to be provided with the subject positions that are made available. Under advanced liberal government, subjects ideally regulate themselves along the values associated with the positive notion of freedom, which means that they strive to be as enterprising and self-responsible as possible. In a society that relies on this type of ethical government of the self, organizations can also be governed at a distance through technologies involving standards of best practice and processes of benchmarking and accreditation.

### Application

Governmentality analyses can be purely descriptive, but they can also be political with an explicit, critical

agenda. Both types of approaches have been common within governmentality studies. In both cases, the attempt to understand the governmental rationalities and techniques should be central. This focus not only on rationalities but also on techniques means that governmentality studies tend to be more empirical than other poststructuralist approaches, examining power in its envisioned practical and technical expressions. However, the focus typically remains on how those who govern conceive and reconceive the object of their government and the subjects who are meant to be governed rather than on how the programs they design are in turn concretely implemented. The concrete implementation can complement the governmentality analysis, but it should not be the core of this analysis.

A governmentality study invites questions about the governed—who are also self-governing—and questions about those who seek to govern. In his influential discussion of governmentality, Mitchell Dean proposes a framework involving four aspects to describe what the analysis of the governed/self-governing subjects can focus upon: ontology, ascetics, deontology, and teleology. *Ontology* refers to what field or substance is meant to be governed; for instance health issues. *Ascetics* refers to how the substance is to be governed; for instance, through prevention programs attempting to responsabilize people about their fitness and encouraging them to go to the gym. *Deontology* refers to who the subject becomes when governed; for instance, self-responsible, healthy subjects who benefits from their fitness in all aspects of their life and experience their exercising practice as fulfilling. *Teleology* refers to why it is important that this substance should be governed, mainly from the viewpoint of society; for instance, the savings in healthcare expenses and the activation of potentially productive healthy people. Nikolas Rose, Pat O'Malley, and Mariana Valverde complement these questions about the governed with questions about those who govern: It is also important to examine who is governing what, according to what underlying rationality, with what techniques, and for which purposes. In their view, a governmentality study should aim empirically to find precise answers to all these questions about both the governed and the governing.

Governmentality lenses have been used in many disciplines and to analyze many different types of

issues in many different types of settings. Some of the most influential studies have dealt with the government of economic life at different levels. The governmentality perspective makes it possible, for instance, to look at how certain political economic discourses and programs at a national or even a global level are translated in very localized workplaces. Some of these studies have focused on how technologies of performance relying on indicators and encouraging employees to conform to best practices are made more efficient through the use of confessional technologies like development discussions. This type of analysis is not limited to profit-making organizations, as an economic governmental rationality has reached all aspects of government under advanced liberalism. Making public services more effective, productive, and efficient, for instance, is a priority of new public management. A governmentality approach may help understand this process, as it involves an activation of users reframed as customers and invited to engage in self-service customization, a prevention calling for self-responsibility in health-related matters, and a responsabilization of people for other risks, whether individual—relating to something like unemployment or poverty—or collective—relating to, for instance, the environment or security/crime. Rather than at the level of the state and formal government, it may be most interesting to analyze governmentality in mundane activities in everyday work and life: The perspective can inform studies engaged in virtually any social setting within a liberal society, where many attempt to conduct the conducts of others, in addition to their own.

### Critical Summary

Governmentality can be particularly well suited as an analytical perspective in a case study of virtually any organization, as the processes of governing others' conducts and self-governing are observable everywhere in today's liberal societies. In addition, a governmentality approach can potentially be useful within most social and behavioral sciences, as it helps to understand human behavior in society, as governed by others, and self-governing, according to certain rationalities. One pitfall for researchers to avoid, however, is a too systematic understanding of power only in terms of governmentality, as sovereign power and

disciplinary power have not disappeared altogether with the advent of liberal government. It is important for researchers to remember that advanced liberal rule is also dependent on its dark side relying on less benevolent forms of power.

## GROUNDING THEORY

---

Grounded theory (GT) is an approach to research offering a systematically applied set of methods to generate a substantive theory. The GT approach can be applied to theory building in the social sciences, and is considered especially relevant to the study of any social phenomenon that is processual in nature. The theory evolved from the idea that theoretical concepts should be grounded in the intersubjective reality of the social world, which is experienced by the researcher with a directed research aim. Substantive theory is primarily based on the data themselves, and the data collection and analysis are essentially linked. Barney Glaser and Anselm Strauss developed this methodology for generating theory when little is

already known, and for providing fresh insight into existing knowledge. According to the later contribution of Anselm Strauss and Juliet Corbin, GT results in a set of relationships that offer a plausible explanation of the phenomenon under study. It links diverse facts in a coherent, useful, and pragmatic way. At the same time, it also has the capacity to reveal the unrecognized or the unknown.

### Philosophical Roots and Sociological Context

GT methodology falls within the tradition of qualitative research. Karen Locke has shown that qualitative researchers adhering to the modernist and interpretative schools have successfully used the approach. Within the qualitative research tradition, the interest of modernists is in establishing how the world might be predicted and controlled, while the interpretivists focus on the subjective reality experienced by social actors. The latter are concerned with lived experiences and seek varying accounts of those experiences, in contrast to the positivist approach, the aim of which is to seek out underlying variables and causal factors of phenomena. GT has intellectual connections to pragmatism and symbolic interactionism, both of which are considered to belong to the interpretivist school. Pragmatists, in general, implicitly assume that models are built from parts of other models and empirical data on the basis of trial and error complemented with some heuristics and intuition. Symbolic interactionism is both a theory of human behavior and an approach to inquiry about human conduct and group behavior. It tackles issues related to the individual in society, but is not concerned with the shape of society. Nevertheless, it recognizes its holistic nature, emphasizes the mutual causation between individuals and their environments, and acknowledges the evolutionary nature of social change. All this highlights the importance of studying the process of change, and the idea that inquiry is always context-bound and that facts should be viewed as both theory- and value laden.

The argument put forward by Glaser and Strauss about the nature, purpose, and possible development of a theory arose from these approaches. However, the GT approach is distinguishable among the interpretivist methodologies

in the sources of data used and in the use of literature to inform and locate the developed theory. In contrast to pragmatism, GT is explicit on the iterative use of the inductive and deductive modes of reasoning.

GT is based on the acceptance of the complexity of social life. In its true sense, it emphasizes context and the social construction of realities. It promotes the notion that the building of realities is an ongoing process of negotiation, reevaluation, and refinement of and between individuals. Consequently, the attributes of the researcher and his or her effects on the phenomenon under study and on the presentation of the findings are considered highly relevant.

### Discussion and Application

Grounded theory is a bottom-up approach in that the results are derived from the study of the phenomenon it represents. It supports the discovery of phenomenon-specific theories and subsequent comparison with other theories. It is discovered, developed, and provisionally verified through systematic data collection and analysis. The work of Glaser and Strauss put specific emphasis on the fact that the connection with empirical reality may help in overcoming the limits of pure conceptualization, thus improving the theory. GT emphasizes induction, deduction, and verification as integral parts of inquiry, and it accepts the duality between deductive (i.e., generalization from a priori conceptualizations) and inductive (i.e., inference of particular facts or observational evidence to general principles) reasoning logic.

In terms of capturing the complexity of social life and the change processes inherent in it, qualitative data may fit the purposes of theory development better than quantitative data. However, GT allows the researcher to use multiple data sources. He or she may apply both qualitative and quantitative evidence and consider real-time and historical data simultaneously. Additional data collection is also allowed whenever the emerging conceptualization calls for it. Essential to this kind of data collection is theoretical sampling, which focuses on the data that may fit the conceptual categories. The aim in the sample selection is either to maximize the similarities that the replication logic dictates in order to increase internal validity, or to

maximize the differences in line with the scope of the theory to enable theoretical coverage. Thus, data collection in this approach aims at generating a sufficiently large number of comparable “incidents” with rich descriptions to enable in-depth comparison, based on which theory can be built.

The analysis comprises the systematic comparison of small units of data (i.e., concepts). It involves the gradual construction of a system of concepts that describes and explains the phenomenon under investigation. The levels of analysis are crucial in arriving at more refined integration of abstract concepts that cover behavioral variation. The concepts on the lower abstraction level define those on the higher level. The data analysis is driven by the emergent theory, in which the key mechanism applied is coding. Coding refers to reducing or breaking down the data, conceptualizing it, and putting it back together in new ways. Category in this instance refers to a code for a concept, its properties refer to its causal conditions and consequences, and the dimensions refer to a range of values that can be attributed to it. Data reduction, which Strauss and Corbin term *open coding*, is the task of selecting, focusing, and simplifying the data. Axial coding, according to the same authors, is about making connections among categories as well as between each category and its subcategories. In so doing, the researcher needs to identify properties and dimensions for each category and subcategory, and to build links between them. Selective coding is the part of the analysis process in which the data are put back together as the emergent theory guides a new and refined integration of the abstract concepts. Data displays and theoretical memos help to entice the researcher away from the data toward abstract thinking. Data displays include tables, matrices, and diagrams, which are helpful tools in the search for patterns. Theoretical memos assist the iterative process between further data collection, data analysis, and theory development.

The GT method calls for early data collection, but this does not mean that it is atheoretical, or purely inductive. Overemphasis on induction would downplay the role of theoretical sensitivity. Yet, the researcher who applies the GT approach has to take care to avoid early internalization of the perspectives and hypotheses of scholars in the immediate field of study.

The principle is that the developing theory should direct the researcher to the literature that best informs, explains, and contextualizes the findings. Grounded theory uses knowledge and theory as informants in the investigation. It involves questioning the data in order to create links with established theory, and therefore requires an understanding of a broad range of established theories and empirical works. Theorizing is the process of constructing alternative explanations until the best fit is achieved between data and explanation. The ultimate challenge is to integrate emergent analytic thinking, and in order to do that the researcher may need to search more broadly in the diverse field of the sciences.

As the emergent framework is based on the constant comparison of various units of data, the methodology offers ways of distinguishing adequate from inadequate knowledge. As long as adequacy improves, the research activity accelerates and becomes more focused. This very focus imposes more self-validating constraints on the research, thereby proving the adequacy of the explanation. Validity is the extent to which a piece of research gives the correct answer. More precisely, internal validity means that the findings make sense and answer the research questions. External validity is the degree to which the findings can be generalized or transferred to other settings. Even at the sample-selection stage the goal is to generalize phenomena to theoretical propositions rather than to populations. Generalization within the GT approach is thus analytic, or theory connected, as the theoretical sampling is focused on filling conceptual categories.

Given the varied social construction of knowledge, the researcher has to describe the context in question accurately and the techniques he or she used, so that subsequent follow-up studies may match them as closely as possible. The more detailed the description, the more it allows the researcher to explain and understand it if applied to a similar phenomenon. In this sense, research taking the GT approach can claim reliability.

Grounded-theory application is evaluated in terms of how the result, that is, the theoretical output, fits the world out there, which is socially constructed and consists of individuals' interpretations. How does the theoretical framework span a range of contexts? If necessary, does it offer modification

possibilities? Is the new framework with its incorporated concepts relevant to the people concerned? The degree of fit with antecedent literature is also an important consideration. Whatever part of the generated theory does not fit or support the existing literature has to be explained in terms of substantive differences. This way the methodology promotes internal coherence and completeness.

Glaser and Strauss first developed GT methodology specifically for sociology. It was promoted to develop sociological explanations of the variability in social interaction. Over the decades it has diffused into other disciplines. One frequently used application in various disciplines is in case-based theory building, with single or multiple cases. Karen Locke, Kathleen Eisenhardt, and Melissa Graebner give examples of successful applications. Andrew Pettigrew reflected on conducting processual research in the context of management and organizations. In realizing the task of interpretation, he found GT specifically useful. One reason for this is because, once the case narrative has been written and the current strategic concerns listed, there needs to be an explicit attempt to interpret the narrative and also to link emerging conceptual and theoretical ideas, both to analytical themes within the case and to wider theoretical debate in the literature.

### Critical Summary

With a view to discussing the strengths and weaknesses of GT methodology, both the researcher and the audience should understand what may and may not be achieved through its application. What use are the results, and when is the resulting theory not suitable? What GT can provide is a way of thinking about a phenomenon in that it reveals a complex relationship between the relevant concepts. These relationships are embedded in the particular context, which sets out sociostructural conditions that support interactions, their consequences, and how they change over time. Such an investigation may have radical implications; however, it may not offer direct solutions to individuals. It is not predictive of the treatment of individual cases, and it is provisional in light of the fluidity of the social phenomena under investigation.

Diffusion from sociology to other disciplines has created some confusion about the meaning of

grounded theory–building. The precise meaning stems from the original focus on the interpretation of meaning by social actors. Further, it refers to the elaborate process of data collection and theory discovery through the hierarchical structuring of categories in which theoretical sampling and constant comparison are central. Some scholars, however, adhere to a broader view. They use the term simply in the context of creating theory by observing patterns within systematically collected empirical data, the theoretical sampling of cases, and/or iteration between the theory in progress and the data. Perhaps the best way of coping with these multiple meanings is to use the term only when the researcher actually uses the original approaches.

Successful conclusions can be achieved if methodological implications are addressed to the actual study, to the purpose and the assumptions according to which the data were collected. The researcher has to give references regarding the version of the GT procedure he or she has applied in order to avoid confusion over terminology and procedures. As a later user of GT methods, he or she should be familiar with the seminal works of the originators Glaser and Strauss, Strauss and Corbin, and Glaser. This should help to avoid generation erosion, which would happen if the constant–comparative method were inappropriately implemented or the research process evaluated against nonappropriate standards. Problems with GT methodology arise when the research does not utilize the full method (i.e., methodological muddling) or has not progressed enough to pass the descriptive stage of analysis. Full and reflexive interrogation of the data is needed in order to allow the theory to emerge and to avoid premature closure.

In his later works, Glaser himself criticized the application of strict coding and the highly procedural version created by Strauss and Corbin. In Glaser's view, the codes could be simply forced on the data, whereas the original idea behind GT was to seek to explain variability by identifying the basic social processes.

In sum, the researcher using GT methods may be able to develop theories of complex real-life processual phenomena. The approach offers tools for making a theoretical contribution during the data-analysis stage. It helps the researcher to utilize the breadth and depth of the data, and hence to incorporate the variety and range of variables. Identifying the basic social process may be the key to pulling a theoretical framework together; in other words, to integrating the environmental, strategic, and operational aspects of complex social processes.

## HEALTHCARE PRACTICE GUIDELINES

---

Healthcare practice guidelines, also referred to as clinical practice guidelines, are intended to help standardize treatment decisions and patient care. These guidelines are used throughout the Western world and intended to serve as algorithms for healthcare providers to use in evaluating patients, determining treatment options, and providing care. The clinical practice guidelines are developed based on clinical research, data gathering, and objective analyses. Healthcare providers worldwide are encouraged to use the thousands of different guidelines to promote a more consistent approach to patient care and decision making. Case studies are frequently used to assess the implementation and effectiveness of healthcare practice guidelines.

### Conceptual Overview and Discussion

Historically, in the Western world, healthcare practice was an individual skill learned at an accredited school of medicine, nursing, etcetera. Providers were educated, examined, and licensed and then expected to apply their knowledge and skills independently to the assessment and treatment of patients' illnesses or injuries. However, in an effort to codify and normalize the treatment and decision-making process, healthcare practice guidelines began to be developed in the latter half of the 20th century.

The concept for creating clinical practice guidelines derives from the need to disseminate the latest clinical information to healthcare providers and improve the quality of care by:

- Standardizing treatment decisions
- Delivering the best outcomes possible
- Maximizing patient safety
- Enhancing cost effectiveness

To accomplish these goals, healthcare practice guidelines rely on analyses of published case studies and other data as the sources for evidence-based medicine. The theory of evidence-based medicine was first postulated by researchers from McMaster's University in the early 1990s. Evidence-based medicine evolved from an effort to refocus clinical decision making and treatment from a subjective undertaking by individual providers to a standardized practice based on published research, clinical data, and technological advances. By utilizing a combination of widely accepted experiential and clinical research evidence related to diseases, injuries, and treatments, healthcare practice guidelines were developed for a wide variety of diagnoses and conditions.

Over the past three decades the creation of healthcare practice guidelines has exploded. According to the U.S. Agency for Healthcare Research and Quality (AHRQ) Web site, in 2008 there were more than 2,300 different healthcare practice guidelines. These guidelines describe the

diagnosis, treatment, and care for patients with diseases ranging from hypertension to malignant bone cancer and from chest trauma to acute cardiovascular accidents. However, the complexity and diversity of the vast number of guidelines being developed throughout the world does not mitigate the fact that critics remain concerned that the proliferation of guidelines will standardize health practices to such an extent that the quality of care will suffer. In addition, while research has shown that use of healthcare practice guidelines does effectively change some providers' behaviors, decision making, and outcomes—many providers do not adhere to them.

The rejection of healthcare practice guidelines has been explained by George Weisz and others as a reaction to the perception that guidelines resulted from politicians' and administrators' desire to control economic rather than healthcare issues. Furthermore, many providers have argued that the use of healthcare practice guidelines reduces their professional autonomy. However, it has also been postulated that the increasing emphasis on clinical practice guidelines results from the sociological imposition of outside forces, by nonproviders, on healthcare decision making and practice. With these varied concerns impacting acceptance and utilization of healthcare practice guidelines, researchers have suggested using theoretical frameworks to enhance provider adoption.

Using the theory of planned behavior is one approach that has been suggested for increasing the acceptance of healthcare practice guidelines. Behavioral change theory provides a mechanism for guideline developers to identify and assess the issues related to behavior change and guideline adoption, as well as methods for evaluation and implementation. Behavioral change theory has the potential to enhance the implementation and acceptance of healthcare practice guidelines by organizing the various components and incorporating evidence-based medicine evaluations of the guidelines.

### Application

Clinical practice guidelines can be used in countless healthcare settings to provide patients with a standardized level of care based on the latest information from published studies and objective analysis. Similarly, assessments of healthcare practice

guidelines provide an ideal opportunity for case study research. From a single case study exploring provider behaviors, decision making, and treatment practices, to comparative case studies examining multiple instances of implemented guidelines and their outcomes, case studies afford researchers an applied approach to assessing guideline development, utilization, and effectiveness.

An example of how a case study approach can be used to inform the development of healthcare practice guidelines can be illustrated vis-à-vis a cancer pain management study. The researchers relied on case studies of cancer patients' pain management to assess the providers' clinical decision making and treatment plans. These case studies included individual interviews with patients, their healthcare providers, and caregivers regarding the patients' pain management and quality of life. The data from the interviews were used in multidisciplinary focus groups of healthcare providers and administrators to evaluate and refine the current pain management policy. Based on the evidence from the case studies, the focus groups developed and disseminated more holistic clinical guidelines for cancer patients' pain control.

### Critical Summary

Healthcare practice guidelines have been used to minimize the variability between providers in the treatment, decision making, and care related to numerous diseases and conditions. This effort toward standardizing healthcare practice relies on case studies, clinical trial research, and publications as the sources for the evidence-based medicine that underlies the development of clinical practice guidelines. Further, with technology and computers, providers have nearly instant access to all types of healthcare practice guidelines and treatment options. However, the drive toward standardization prompted providers' concerns that guidelines were being developed to control and regulate their behaviors for economic- and administrative-, not healthcare-related reasons. Case studies can be used to evaluate the providers' behaviors as well as the outcomes related to use of healthcare practice guidelines.

## HERMENEUTICS

---

The task of the hermeneutist is to engage in the interpretation of texts informed by the epistemological insights of hermeneutic philosophy. These insights encourage reading between the lines or ascertaining the subtext of the text. This particular method is useful for case study research if the researcher is investigating any sort of textual documents for a deeper understanding into human behavior, actions, organizational culture, and communication.

### Conceptual Overview and Discussion

The classical Greek word *hermeneus* means “interpreter” or “expounder.” Hermeneutics is about interpretation or even translation; it is about clarification—making the obscure less obscure. The hermeneutical tradition started in biblical studies and philology in order to decipher the authentic meanings of biblical texts. Since the 19th century it has been embraced by the humanities and more recently the social sciences, particularly in the interpretive sociological tradition in which the quest for causal explanation and prediction is replaced with the quest for understanding human actions (*verstehen*). What is of interest is how the

text speaks through the person rather than finding an objective scientific reality behind the text.

The term *text* refers more broadly to all kinds of written documents. Texts are generally finished texts intended for communication outside the original situation. They have endured physically, been witnessed, and can be studied when the originators are no longer present. Examples include electronic mail, financial statements, agendas and meeting minutes, advertisements, official policy letters, articles, films, and transcribed interviews. Contemporary philosophers (e.g., Michel Foucault) extend the meaning of text to what is visual or action oriented—the text of the body itself.

Hermeneutic philosophers have set out to answer more than the question of what constitutes a text from which understanding (*verstehen*) can be sought. They have also asked: Through what process can it best be understood? What constitutes authentic textual interpretation?

Friedrich Schleiermacher, known as the father of modern hermeneutics, calls attention to the necessary art form of doing hermeneutics in that the reader of a text must be as much an artist as its author was. The anxiety to be understood (the text along with the author) and the anxiety to understand (the interpreter) are meaningfully negotiated when the hermeneutist is disciplined and artistically sound. For this negotiation to come about authentically, hermeneutists must arrive at their interpretation though attending to the psychological and grammatical dimensions of textual reading. The former pertains to the interplay between reader and text with the understanding that texts are the product of the author’s historical location and social positioning. If this is not taken into account, misunderstanding between the text and interpreter can result. The latter dimension is concerned with careful examination of linguistic and syntactical structures of the textual language.

Wilhelm Dilthey adds that in addition to the author’s mind-set, one must take into account his or her broader cultural milieu. Second, he names the text as not only more than a piece of writing, but a cultural artifact. Dilthey coined “the hermeneutic circle,” which refers to the principle that the “part” (e.g., the text or pieces of the text) can be understood only with reference to the “whole” (e.g., the whole text and/or the cultural context) and vice versa. The meaning resides in this circular

understanding where the goal is to capture the *spirit* rather than the *letter*. The “part” and the “whole” are not exclusive but interpenetrate one another. The interpretation of meaning ends when the hermeneutist reaches good “*Gestalt*” or an inner unity free of logical contradictions.

While Dilthey and Schleiermacher attend to the relationship between the author (and his or her social–historical–cultural location) and text, Martin Heidegger and Hans-Georg Gadamer shift attention to the relationship between text and interpreter. Heidegger calls for consideration of the “forestructures of understanding” that denote the presuppositions, ideologies, and existing familiarities with other texts with which the hermeneutist approaches the text. These must be acknowledged and brought into the dialectical relationship between hermeneutist and text, not quelled in the false quest for objectivity. Gadamer identifies these as productive and nonproductive prejudices. Nonproductive prejudices refer to those that hinder authentic *verstehen*; the productive prejudices that foster understanding should be cultivated in the dialectical relationship.

Critics of Gadamer’s approach argue that his non-productive prejudices are aligned with a hermeneutics of suspicion, while the productive are aligned with a hermeneutics of (blind) faith. A hermeneutics of suspicion refers to the method of interpreting texts cautiously, aware that the surface-level meaning of a text may be an effort to conceal the political interests that benefit some at the expense of others. The task of the hermeneutist of suspicion is to strip off the mask, exposing those interests. Jürgen Habermas and Paul Ricoeur, both critical hermeneutists, argue that the hermeneutics of suspicion is a positive force in arriving at authentic meanings of texts.

Habermas, the father of critical hermeneutics, asserts that texts are derived from social relations of power and domination, and these oppressive aspects are concealed in texts. He calls for a process-oriented critique of the text’s ideologies (*Ideologiekritik*). Another critical hermeneutical position holds that hermeneutists must be careful not to fall into the trap of “intentional fallacy.” Questions of an author’s intentionality have drawn attention to the reality that authors cannot always state their own personal intentions and desires, but may be impeded by sociopolitical forces and organizational cultures.

Ricoeur affirms the importance of applying a hermeneutic of suspicion to uncover class interests and conflicts, but affirms that this must be in conjunction with a hermeneutics of faith. A hermeneutics of faith calls for suspension of disbelief, in which the text becomes the world we inhabit, participating in upholding its claims on us. Following in the tradition of Habermas and Ricoeur, this entry now turns to one example of an application of critical hermeneutics in social science research.

### Application

Nelson Phillips and John Brown used a critical hermeneutics methodology to investigate a case study that centered on an advertising campaign conducted by Syncrude Canada. Syncrude is a joint venture company composed of numerous energy companies, the federal government of Canada, and the provincial government of Alberta. The company exists to exploit the petroleum resources in the “oil sands” of northern Alberta.

The researchers used the case study to illustrate a five-step methodology of employing critical hermeneutics in organizational studies based on Ricoeur’s and Thompson’s work. Three magazine advertisements placed by Syncrude were analyzed both from a social-historical perspective and from a formal (structural/conventional) perspective. Then the two perspectives were negotiated through a dialectical process and synthesis in the moment of interpretation-reinterpretation to arrive at a final interpretation of the meaning of the textual ads.

The formal analysis consisted of Roland Barthes’s threefold semiotic approach by which a text can be examined at three levels—denotation (literal meaning), connotation (that to which the literal meaning refers and signifies), and myth (how the text draws upon wider cultural myths). Via this process, the hermeneutists demonstrated how the Syncrude ads attempted to shape their corporate image by creating an interpretive frame, morphing the viewer’s understanding of the organization by drawing on myths of supporting the future, the traditional family, social responsibility, aboriginal and other environmental sensitivities, and nationalism.

The social-historical analysis examined the producer, targeted audience, and intentionality of the

text through a consideration of the sociopolitical and economic climate. The hermeneutists drew on more than 300 newspaper and magazine articles over a period of 10 years to craft the social-historical background of the advertisements. Syncrude was found to be facing difficulties with uncompetitive production costs, limited cultural exposure, tensions from environmental activists, and a general diminishment of support from key government and private stakeholders.

During the moment of interpretation-reinterpretation, the hermeneutists considered alternative meanings and interpretations of the texts presented by Syncrude in an attempt to disrupt the corporation's political framing rooted in the previously mentioned myths. They examine the asymmetrical power relations among the various stakeholders with an interest in the company, its activities and how both are perceived, whose voices were unable to contribute to the shaping of the organization's image, and what information was left out. Their hermeneutically derived findings suggest that the meaning behind the advertisements reveals an attempt to present the company as fiscally, socially, and environmentally responsible in order to secure government and public backing that the organizational establishment desires in order to prevent future scrutiny and roadblocks from environmental, legal, and government agencies.

### Critical Summary

Although the above application focused on critical hermeneutics, the hermeneutic tradition is much broader and richer. Yet the foundation of all hermeneutics relies in the relationship between the interpreter and the text. It is relational, rather than schismatic and objective. The hermeneutist attends to the text, the text attends to the hermeneutist in a metaphorical sense, and both allow their own prejudices, presuppositions, cultural inheritances, and social locations to enter into an unapologetic, reflexive dialectical relationship in order to arrive at meaningful understanding.

## HIGH-QUALITY ANALYSIS

---

High-quality analysis refers to both the robust ways in which the data were examined and the style and method of presentation of the analyses. Analysis occurs throughout the case study, both at the site through systematic documentation in field notes and protocols, and after field work is completed through methodical interrogation of the data. High-quality analysis is both an ethical and a technical issue. Ethically, it involves ensuring transparency in data analysis procedures and decision making. Technically, high-quality analysis involves explicit unveiling of the systematic ways the data were examined and the rationale for proceeding in such ways. Central to high-quality analysis is identification of the theoretical orientation of the researcher and coherence with research theories and the research questions. High-quality analysis is challenging because it requires a simplification of data to aid understanding without obfuscating complex relationships.

### Conceptual Overview and Discussion

Analysis is a systematic search for meaning that proceeds inductively (from the specific to the general) so that general statements about the phenomenon

can be made. Analysis is considered to be high quality when the researcher has explicitly documented both the processes for analyzing the data and the justification for proceeding in such a way. The method of analysis in case study research depends upon the content, question, methods, situation, scope, and theoretical orientation of the case.

Arguably, high-quality analysis begins at the earliest stages of research, at which time critical design decisions are made related to the framework and the unit of analysis to be used. Data analysis that occurs during the earliest days of collection serves to inform the researcher about shifts that may need to occur in the protocols. Analysis of researcher field notes helps the researcher to capture emerging understandings and insights while they are still fresh. Of course, the bulk of the data analysis happens once the work is completed at the field site.

Yvonna Lincoln and Egon Guba purport that trustworthiness is the most critical aspect in evaluating the quality of a research study. Trustworthiness involves establishing credibility (confidence in the “truth” of the findings). Three techniques for establishing credibility are triangulation, member checking, and negative case analysis (i.e., including a search for rival explanations).

The best technique for establishing credibility is a thick description, which provides an accurate view from which to discern points of significance and critical insights. Triangulation means that three different sources of data have been referenced to support the finding. Member checking (e.g., having participants read and make commentary on their own interviews) provides repeat opportunities for participants to say and show what they mean. Negative case analysis is the process of rewriting or reimagining the hypothesis as more information is made available.

Dependability (that the findings are consistent and could be repeated) is another method of assessing the quality of case study research. It is best established through an inquiry audit. An inquiry audit is the systematic process of checking the analysis for procedural and organizational quality using criteria and an audit trail. A well-organized audit trail aids peer reviewers in evaluating the quality of the analysis by breaking down the data by class, type, and source. Audit trails

permit confirmability (the extent to which the findings represent the study participants’ perspectives). Robust analytical frameworks are transparent and coherent, enabling readers to make informed critical judgments about the quality of the work.

### Application

Jon Ritchie and Lyn Spencer offer an informative example of a process for conducting high-quality analysis. In the first stage, the researcher conducts a survey of the literature and becomes aware of what is known about the phenomenon and of the language used to discuss the problem. The researcher might also become aware of the types of materials used to collect data and the breadth of data that he or she has personally collected. In the second phase, the researcher develops a tentative thematic framework for the research question. This involves creating a system of markers or indicators. The next step is to index all of the materials, applying the framework to the analysis of the data. After this, the researcher makes decisions about how to display the data in a way that makes sense. The data are taken out of context and put into an order that corresponds with the themes. Finally, the researcher makes explicit the emerging dynamics of the phenomena, providing an interpretation of the data and showing relationships between parts and wholes. Note that this description about data analysis may give the false impression that it is purely a systematic process. While a systematic approach is critical, the process is iterative and requires researcher discernment, which is subtle but intentional effort at demonstrating perceptiveness, awareness, and insight in dealing with the data set.

### Critical Summary

High-quality analysis is the backbone of substantive case study research. The researcher’s integrity, knowledge, and skill infuse the analytical approach with rigor. Transparent, systematic procedures for analysis enhance the likelihood of an audit trail that bears up under peer scrutiny. Such high-quality analysis respects the central purpose of case study work, which is to help us notice and understand particular aspects of the human experience that are

often overlooked or unexamined by other types of research. Access to such nuances in human understanding is made possible through the researcher's methodical interrogation of data and multiple approaches to calling into question emerging hypotheses before arriving at general, compelling statements about the phenomenon. Finally, the writing skills of the case study researcher are paramount for the clear communication of the research outcomes, making them accessible to both a critical and interested audience.

---

## HISTORICAL MATERIALISM

---

Associated specifically with the analytical approach of Karl Marx and the intellectual tradition developing from his work, historical materialism is a method of identifying and organizing data that emphasizes the priority of socioeconomic factors as the locus of causal significance. More recently, this has been associated with what has been called the “political economy” approach in the social sciences. Directing its attention to the economic framework of society, historical materialism identifies a “class structure” produced and perpetuated by the specifics of the prevailing “mode of production.” It concentrates upon the way in which society is dominated by the ruling class that owns and/or controls the economic resources, and the way in which its domination “exploits” other classes and produces “class conflict” and even “class war.”

### Conceptual Overview and Discussion

Historical materialism should not be confused with “dialectical materialism,” which was developed after Marx’s death by his closest collaborator, Frederick Engels, and became the official doctrine and ideology of the Soviet Union (1917–1991). This was developed as an all-encompassing theory of the entirety of human knowledge, of its structure and development. By contrast, what we call historical materialism (a term not used by Marx himself) is an analytical approach to human situations (from the most individual to the most global) in the specific conditions of different times and places.

The term *materialist* refers to the assertion and directing view that the values and assumptions of the human actor are conditioned primarily by her or his experiences and actions (particular productive or economic behavior) in the specific environment produced by the mode of production prevalent at the time. “Historically,” the mode of production has been dynamic, changing as a result of human activity. In conjunction, as human beings have changed their relationship with the physical environment (nature), they have changed themselves—how they live, how they are organized, and what they believe.

Arguing that the mode of production (the economic framework of any society) has always produced a dominant form of property, historical materialism asserts that the class that owns that property will be the ruling class in society and will control its politics and values or culture. Therefore, at any historical moment, in any specific historical circumstance, one can identify a dominant class.

In the modern period, following industrialization and urbanization, this theory identifies the owners of industrial (and, sometimes, “postindustrial”) property by the means of production (i.e., industrial capital), normally referred to as the *bourgeoisie*, as the dominant class. This is also taken to include corporate capitalism and finance capitalism. The central bourgeois values are presented as the right to private property, the pursuit of profit and wealth as a valuable contribution to the development and well-being of society, the acceptance of inequality as inevitable (and even desirable)—all of which must be protected and promoted under the legal and political framework of the state. The operation of the “liberal democracies” as seen particularly in

Western Europe and North America is regarded as the quintessential form and character of bourgeois domination.

Aiming at an understanding of “developed” economic and social systems, this theory has always placed industrial capitalism at the center of its interest. Yet it can be used as an analytical framework for any economy, from cavemen to contemporary capitalism. Further, even in its 19th-century origins, this theory regarded capitalism as having become international or global. Consequently, analysis of local questions could (and should) be viewed in the larger context of capitalist domination and the integration of the economic forces of the entire planet. Those who would analyze a local situation should always keep the larger context in consideration.

In conjunction with the identification of a specific class rule, we also have the necessity of “class conflict” and/or “class war” as a corollary. This can be seen from two perspectives:

First, emphasizing the operation of any functioning system, one can identify the ruling class and the ruled or “exploited” class(es). When looking at industrialized societies, researchers have tended to follow Marx’s guidelines. The main two classes to be identified are the bourgeois owners and those who survive by selling their labor for a wage (the working class or “proletariat”). Less important in “developed” systems (but very often of great importance in developing countries) are the small or “petty” bourgeoisie (who are constantly being reduced or “competed out of existence” by the big bourgeoisie), the peasants or small farmers (who are being eliminated from agribusiness), and the so-called *lumpenproletariat*—the latter being the dislocated mass of declassed persons who gather in and around modern cities as their means of subsistence are denuded by the concentration of economic resources into the hands of corporate capitalism. Each of these classes has its own interests, which often places them in conflict with each other. The principal “objective” conflict is between the two main classes—the proletariat and the bourgeoisie. However, an understanding or “consciousness” of the situation may not be generally clear to the members of each of these classes. Researchers will often use this approach to “reveal” unspoken evidence of class identity, exploitation, and conflict in the normative parts of their studies.

Second, class conflict is presented as a vehicle of political change. Developments in the means of production produce new classes and new class relations. The bourgeoisie, having gained economic and social influence with the development of capitalism, established political power—sometimes violently (as in the French Revolution of 1789), sometimes through taking control of the constitutional framework (as in the United States). Historical materialism often sees developments within this victorious capitalism as the harbinger of its defeat. As socialism, the theory sees the resolution of class conflict in the capture of a centralized and productive capitalism by a mobilized working class, and the administration of the economy for a “general” or “common” good.

### Application

Historical materialism always identifies bourgeois property as inextricably bound up with the exploitation of members of the working class. Simply put, the wealth of social production is denied to the mass of society that actually does the producing. To see the use of the methodology in specific cases one could do worse than going to Marx’s own writings, which are models of the approach. His studies of the revolutionary situation in France in 1848, of the rise of Louis Napoleon to become emperor of France in 1851, of the character of parliamentary legislation in England—and many more in his voluminous writings—all use this paradigm to identify the parameters of the projected analysis, to isolate and organize the data, and to analyze it with a coherent purpose and direction.

The approach can be used without difficulty to study small and large questions involving trade unions, labor strikes, crime and criminal populations, women in the workplace, and any circumstance involving human labor. Novelists have been drawn to its concerns—as John Steinbeck’s writings make obvious (e.g., *The Grapes of Wrath*). Indeed, as an approach to understanding the human condition, it touches upon every aspect of human existence.

### Critical Summary

A few words concerning the “bias” of the approach are worth noting. Its proponents often call themselves

“scientific socialists” because they deal with the facts of specific societies, and show how practical choices can be made by those who wish to reduce human exploitation and misery. Many would argue that this is not a “scientific approach” but an “ideological approach,” the purpose of which is not to provide coherent knowledge, but to mobilize the reader into joining a struggle against bourgeois society. If by “scientific” we mean a “value free” description of the facts of a situation, and how they are causally related, this is true. By these standards, however, very few pieces of research could be called scientific. The selection of data and explanation of their significance always reflect preconceptions held by the researcher. It is perhaps better to have these “up front,” as does the historical materialist, than to pretend that they do not exist. Further, those who claim to be avoiding prescriptive elements (i.e., preferences and recommendations) can be accused of being conservative supporters of the existing situation. Giving information to those in power, while “sitting on the fence,” can only help maintain the continuing domination of existing elites.

However, in terms of its data selection and analytical concepts, historical materialism can be said to fail to identify variables and situations in which factors not salient to the approach are of primary and autonomous significance. These can be such factors as religion, gender, and ethnic identity—in fact, any group identity that demands consideration through its very existence and its own sense of value and importance. Other concepts and tools of analysis are called upon at this time. Nonetheless, historical materialism is an integral element in the scholarship of our times, used in part or in whole by Marxists and non-Marxists.

## HOLISTIC DESIGNS

---

Holistic case study designs build a research framework that draws from an array of stakeholders. The design, implementation, and analysis should facilitate a synergistic combination of various aspects or elements of the case study. Thus a holistic case study is composed of various components, and the challenge for the researcher is to create a credible synthesis of these elements of knowledge.

### Conceptual Overview and Discussion

Case study research per se is holistic in that it must portray the broad context of the case in order for it to be meaningful. Context, however, is a definable term that, depending on the terms of reference for the case study, may take on markedly different parameters. Context can include the physical, social, cultural, symbolic, and psychological environments of the case study.

Holism is a theoretical construct that can be traced to William James's *Principles of Psychology* in the notion that an object of consciousness gains its meaning from its embeddedness in the context from which it emerges. This means that we come to understand things from their surroundings. Approximately a decade later, Edmund Husserl also articulated the idea that a phenomenon is meaningful only by understanding the web of interconnections from which it arises. The relation of figure to ground would later find its way into the Gestalt philosophers' lexicon, thus popularizing the holistic approach. Holism, then, is about understanding something as part of a larger or broader whole.

The principle of holism is to see the entire context for our understanding. Holism moves beyond an elementalistic notion of component parts that combine in a piecemeal way to create an entity. Rather, holism asserts that a broader approach is required to understand phenomena in their totality or *situ* where the whole is greater than the sum of its parts. Martin Heidegger, a student of Husserl's, advances the importance of our interpretations. Heidegger's point is that we make things meaningful by trying to understand their contexts. In the realm of case study approaches, holism is an interpretive standpoint of the researcher. Holism will be a function of what the case study's purpose is in the terms of reference. Therefore holism is about the interpreter's design for what the big picture is and what that entails.

Robert Stake defines three relevant variations on case studies: intrinsic, instrumental, and multiple case studies. Intrinsic case studies are studied for their own particular idiosyncrasy and ordinariness. They are studied for their own sake. Instrumental case studies are examined for their potential to enhance understanding of an issue or phenomenon. The case *per se* is less emphasized than the theoretical insight it might offer for a construct or concept. When several cases are selected to accomplish this instrumental goal, then the study falls into the genre of the multiple case study. The construct of holism takes on nuanced interpretation for each of these typologies.

Holism in case studies with an intrinsic frame of reference needs to consider the various environments that the case crosses. For example, if the case study is of an individual, then it might take a social ecological approach wherein the person is the focus but also the person's relationships with family, with other organizations, and with other institutions of culture. If it is of an organization, then it might look at all the other organizations with which the organization's staff interacts on a regular basis. Of course all of this is a judgment call that is based on a balance between holism and feasibility, which always includes resource constraints. In designing an intrinsic case study, the researcher or team of researchers may wish to start with an ideal holistic approach and then prioritize their work in terms of feasibility. If the case is meant to be intrinsically self-contained, then holism contributes to the overall coherence of the understanding that emerges from the triangulation of diverse perspectives on the particular case.

If the case study is meant to be instructive of other generalities and has an instrumental term of reference, the implications of holism are interpreted somewhat differently. If it is to be a single case study intended to generate theory, then the selection of the case itself must take on a holistic perspective. The research team must determine the extent to which a particular case can be representative of a broader set of cases. Of course they will have to provide a wealth of empirical material to describe the case adequately so that the audience for their project can also determine the representativeness and hence relevance of the project to their own interests or theory. Where the terms of reference include a multiple case study selection with an instrumental purpose, then the cases can be selected purposefully to expose the unique idiosyncrasies that emerge across different environments of similar cases.
