Notices

Knowledge and best practice in this field are constantly changing. As new research and experience broaden our understanding, changes in research methods, professional practices, or medical treatment may become necessary.

Practitioners and researchers must always rely on their own experience and knowledge in evaluating and using any information, methods, compounds, or experiments described herein. In using such information or methods they should be mindful of their own safety and the safety of others, including parties for whom they have a professional responsibility.

With respect to any drug or pharmaceutical products identified, readers are advised to check the most current information provided (i) on procedures featured or (ii) by the manufacturer of each product to be administered, to verify the recommended dose or formula, the method and duration of administration, and contraindications. It is the responsibility of practitioners, relying on their own experience and knowledge of their patients, to make diagnoses, to determine dosages and the best treatment for each individual patient, and to take all appropriate safety precautions.

To the fullest extent of the law, neither the Publisher nor the authors, contributors, or editors, assume any liability for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of any methods, products, instructions, or ideas contained in the material herein.

*To the memory of my father, who was the kind of teacher
I have always tried to be, and of my sister, whose too-short
life was devoted to helping handicapped children.*

— Rhea Paul

A Note to the Instructor

This book attempts to tell students everything they ever wanted to know—and then some—about child language disorders. It covers the entire developmental period and delves into many additional concepts that are important to the treatment of child language disorders, including prevention, syndromes associated with language disorders, and multicultural practice. The fourth edition of *Child Language Disorders from Infancy through Adolescence* brings a tremendous new resource to this work: Dr. Courtenay Norbury of the Department of Psychology at Royal Holloway, University of London, has joined me in updating this edition. Dr. Norbury is one of the foremost young researchers in child language disorders in the world today, and she has an astonishing command of emerging evidence on genetic, neuropsychological and neurophysiological aspects of child language disorders. Her perspective adds greatly to the currency of this edition. She also brings with her a commitment to integrating all forms of linguistic communication into our work. So a major change you will see in this edition is a heightened emphasis on the effects of language disorders on the acquisition of reading and writing, not only in school-aged children and adolescents, but in their emergent stages in toddlers and preschoolers. A second change is also thanks to Dr. Norbury. Because of her expertise and our shared interest in autism spectrum disorders, we have added specific recommendations for assessment and intervention approaches for this population to each of the chapters in Sections II and III.

In reviewing the literature since the third edition of this text, one of the changes we have been pleased to see is that many of the intervention approaches described have now undergone more rigorous evaluation. When I prepared the third edition, I found many studies that systematically examined the efficacy of approaches that had been advocated extensively and used widely without much basis in empirical evidence. Preparing the fourth edition, we have been happy to learn that many of these studies have now been aggregated and subjected to meta-analyses, so that the evidence in their favor has become clearer and stronger. This has been one of the most gratifying aspects of updating the text—seeing our field advance as it develops a stronger commitment to and a broader basis for evidence-based practice.

As before, this book is relatively short on theory (although not quite so short as it was before Dr. Norbury signed on) and long on clinical application and concrete procedures. Our goal has been to provide a broadly based, practical introduction to the field of language pathology to students planning a career as clinicians in speech-language pathology, students who need to know what to do that first Monday morning of their clinical career, but who also need to develop the ability to think critically and creatively about the myriad kinds of clinical problems they would encounter in the course of their practice.

Our hope is that students will use this book during their introductory language disorders course and will also find it a helpful reference as they progress through their clinical education and even into their professional practice. For this reason, students reading the

book for the first time may feel that it is too comprehensive, that they cannot possibly absorb all the information in it in one or two terms. They are probably right. Our hope is that their instructors can help them to understand that they can return to the book later and not only refresh their memories, but also take in more of it as their experience broadens and they have more background information and more clinical savvy with which to approach it. Helping students understand that they do not have to master the entire volume the first time through, that they will have opportunities as their career goes on to assimilate more of the material, can help alleviate their anxiety. What they should get from reading the book the first time is knowledge of the basic concepts and vocabulary used in the field, an overview of its issues and controversies, an understanding of the scope of communicative difficulties that make up child language disorders, and a sense of how a speech-language pathologist approaches the processes of assessment and intervention.

In order to provide this sense, case studies and vignettes are included throughout the book. These are meant to serve as examples of applying the material in the text to some real-life situations. In using the case studies in class presentations, one approach might include having students work in groups to come up with alternative approaches to the ones given in the book for dealing with the cases presented. This can help students develop a sense that there is no one “right” way to deal with a client and that several different approaches might be equally appropriate, so long as each takes the client’s needs into account. Another way to use the case studies is to have some students present their own clients as case studies for the chapters that apply to them. They can use the case studies in the book as models for applying the principles discussed in the chapter and use a similar approach to come up with an assessment or intervention plan for a client being presented. If the students work on the case in a cooperative learning arrangement, with several groups of four to six students working independently to come up with a plan for the case to present to the whole class, the diversity of possibilities for addressing a client’s needs can again be illustrated.

As the Preface of this book states, much of the material contained here represents the authors’ opinion or point of view. As a result, many instructors who teach courses in child language disorders will find themselves in disagreement with some aspects of the book’s content. Our hope is that instructors will let students know when this happens, and give them that alternate point of view. As we’ve tried to emphasize throughout the book, language pathology is not a field in which there are long-established sets of accepted premises and practices. Our field is lively with controversy and differing opinions about how to conceptualize, organize, categorize, explain, assess, and treat child language disorders. Students should be aware of this ferment. The best way to give them this awareness is for an instructor to focus on points of disagreement with the text, to elaborate and explicate the differences, and argue an alternative point of view. Students exposed to opposing points of view from two authoritative sources—their teacher and their textbook—have a good chance of becoming critical thinkers about

the material in their coursework and later in their professional practice.

This book is organized into 14 chapters, which could correspond roughly to the 14 weeks of a typical semester. If the book is being used to teach a one-semester course, one chapter of the book could be covered during each week of the term. Increasingly, though, programs in speech-language pathology are expanding their language curriculum to cover two terms rather than one. Some programs divide the curriculum into assessment and intervention portions. Others divide along developmental lines, teaching early assessment and intervention during a first term and language learning disorders in school-age children the second. If this book is used over a two-term sequence using an assessment/intervention structure, the chapters could be covered in the following order:

Term 1	Assessment
Chapter 1	Definitions and Models of Language Disorders in Children
Chapter 2	Principles of Assessment
Chapter 6	Assessment and Intervention in the Prelinguistic Period
Chapter 7	Assessment and Intervention for Emerging Language
Chapter 8	Assessment of Developing Language
Chapter 10	Language, Reading, and Learning in School: What the SLP Needs to Know
Chapter 11	Assessment of Language for Learning
Chapter 13	Assessing Advanced Language
Term 2	Intervention
Chapter 3	Principles of Intervention
Chapter 9	Intervention for Developing Language
Chapter 12	Intervention at the Language-for-Learning Period
Chapter 14	Intervention for Advanced Language
Chapter 4	Special Considerations for Special Populations
Chapter 5	Child Language Disorders in a Pluralistic Society

If, on the other hand, the sequence is organized along developmental lines, the chapters could be covered as follows:

Term 1	Early Assessment and Intervention
Chapter 1	Definitions and Models of Language Disorders in Children
Chapter 2	Principles of Assessment
Chapter 3	Principles of Intervention
Chapter 6	Assessment and Intervention in the Prelinguistic Period
Chapter 7	Assessment and Intervention for Emerging Language
Chapter 8	Assessment of Developing Language
Chapter 9	Intervention for Developing Language
Term 2	Working with Language Learning Disabilities
Chapter 10	Language, Reading, and Learning in School: What the SLP Needs to Know
Chapter 5	Child Language Disorders in a Pluralistic Society
Chapter 11	Assessment of Language for Learning
Chapter 12	Intervention at the Language-for-Learning Period
Chapter 13	Assessing Advanced Language
Chapter 14	Intervention for Advanced Language
Chapter 4	Special Considerations for Special Populations

Finally, if an undergraduate course is included in the child language curriculum, the first section of the book, Topics in Child Language Disorders, could serve as the text for the undergraduate course, and Chapters 6 through 14 could be covered in the graduate curriculum.

Most of the chapters on assessment contain detailed procedures for doing analyses of various communicative behaviors. Some of these contain sample transcripts or other material on which students can try the analyses being presented. The best way to learn these analyses is by doing them, either on the transcripts given in the book or on others provided by the instructor. Having students work in groups, again, reduces their anxiety and provides more heads addressing the problem. Using class time to practice some of the analyses or assigning students to do them as group projects outside of class can be effective ways to be sure that students “get their hands dirty” with the nitty-gritty of analyzing communication. Having done so will give them more confidence to try some on their own and, we hope, to continue using communication analyses in addition to testing as part of their professional practice.

As stated in the preface, the answers to the exercises given in the book are, like all language sampling results, subject to disagreement. If disagreements with the answers given to the exercises occur, this is an excellent opportunity to discuss the reasons for the disagreement and to probe the justification for the opposing judgments. It may be that the instructor and class together will decide that their answer is better than the one given in the text. Over the years the text has been in use, I have received feedback from instructors who worked through the communication samples with their classes, disagreed with the answers in the text, and wrote to let me know. At least two of our analyses have been changed, because instructors were convincing in their arguments. This kind of exercise, too, helps students realize the subjectivity involved in most communicative analyses and brings home the point that so long as analyses are thorough, thoughtful, and careful, they do not always have to be in exact agreement to be useful in intervention planning.

Each chapter has an accompanying study guide at the end to help students review the material. Some instructors may wish to use the study guides to structure discussion of the topics in class. Students also can be encouraged to form study groups and discuss the questions in the guide together. Taking questions from the guides to elicit essay responses on examinations is another way to use them. Students can be encouraged to study the guides for a particular set of chapters on which they are to be tested, and can be told that examination questions will be chosen from among the questions in the guides. I have found this method to be an effective way of getting students to study the full range of material covered, and still have a reasonably small number of questions for them to answer on a 1- or 2-hour examination.

Suggested projects for each chapter are provided at <http://evolve.elsevier.com/Paul/Language/>. These can be used in several ways. Students can be asked to choose two or three of the suggested projects from the chapters covered each term and turn them in as short papers. Some of the projects also lend themselves to in-class cooperative learning activities. Each set of suggested projects contains several ideas for research papers as well. Instructors might have students choose a research paper subject from the topics listed in the chapters covered for a particular term. In my courses, I have students do two short papers and one 10- to 12-page research paper each term, using the suggested projects for the chapters covered during that term.

The companion website also offers a video vignette to accompany each chapter. These provide additional examples drawn from topics covered in the chapter. Some contain communication samples for analysis, some provide visual models of various approaches to intervention, and others show how children at particular developmental levels manifest language disorders. There are also some comments by parents to help students understand family perspectives. These can be used as in-class material or students can be assigned to view them on their own and discuss them or apply concepts discussed in class to each one. Our hope is that the video vignettes will bring a touch of authenticity and save the instructor hours of YouTube searching!

We hope instructors will find using this book helpful in preparing their students for practice in child language disorders. In some ways, having a comprehensive text should make this job easier. It will no longer be necessary to gather reams of reprints and handouts

to copy and distribute in order to cover all the material that needs to be covered. It should no longer be as difficult to find video samples, case studies, and transcripts with which to illustrate points made in class; at least a starter set is provided here. Teaching child language disorders, though, will continue to be a challenge. It requires helping students begin to assimilate the vast amount of information that has been accumulated and letting them know that it won't all stick with them after just one pass. It includes helping students to accept the degree of flux and tension over ideas in the field and teaching them by example to find a way to develop their own point of view on controversial topics. It means imparting the skills to master many specific procedures and concepts without losing sight of the need to remain flexible, creative, and attuned to the needs of each client. While it is hoped that this book can help instructors to meet these challenges, it is certain that teaching child language disorders will remain an exciting and demanding endeavor.

Preface

One thing you will notice right away as you read this book is that it is written in first person. It's cranky, preachy, and personal. Many of the positions taken here will be debated by others in the field. Your instructor, in fact, may disagree with some of the material in the book. It is this lack of consensus among experts in language pathology that prompted us to write this book as we did, in a style that constantly reminds the reader that a lot of what it contains is opinion rather than established fact. Language pathology is a relatively young field, and many of its tenets, assumptions, and paradigms are still in the process of being established. Given this state of affairs, it would be inaccurate to suggest to students that there is a broad consensus about its basic issues. It's just not true, although it is more true now than it was when the first edition of this book appeared, and changes in this edition reflect the evolution of our field. Still, a range of opinion exists, and we've given you our perspective on it. Your instructor's point of view may differ, but our hope is that when it does, you will be exposed to both sets of thinking and be in a better position to establish your own view. While it may seem confusing at first to be told that your textbook does not contain the last word on every question, learning to live with this kind of "creative confusion" is part of what it takes to develop into a thoughtful and critical professional, one who evaluates information rather than merely "consuming" it.

Creative confusion reigns even in the text's practice exercises. The chapters on assessment contain several example transcripts on which you can try the analysis methods discussed in each chapter. Answers to these practice exercises are given in the appendices to these chapters. We've called these "our" answers, rather than the "right" answers. That's because you and your instructor may disagree with some of them. Language pathology is not an exact science. There are no laboratory tests or firmly established quantitative measures. Many of the analyses we do in our business involve a considerable amount of judgment, and even careful judges can sometimes disagree. If you or your instructor disagrees with a judgment we've made about a transcript, consider the opposing positions and try to evaluate the data in light of each. You may come to the conclusion that your analysis is correct and ours is in error. That's happened more than once over the years in which this book has been available. Several times instructors have written that they disagree with one or our answers to the analysis practice items, and in several cases, they have convinced us we were wrong and they were right, so changes in our answers have been made. Again, the important thing is not to decide which answer is right, but to think each decision through, and to develop a consistent set of criteria that you will apply reliably to all the analyses you do, whether or not it conforms to ours. If you have a good justification for your position, stick with it. Developing a clearly delineated set of criteria for analyzing the language you study is the goal of these exercises.

The book is organized into three sections. The first deals with some issues in the practice of language pathology with children that cut across developmental levels. These issues have to do with

how we define and organize language disorders, and the basic principles we will try to follow in assessing and intervening with children at any developmental level. Some other topics that apply to children of any age include understanding the causes of language problems with an eye toward making concentrated efforts to prevent them, knowing something about the various syndromes and conditions that often accompany language disorders in children, and developing techniques for working with children who come from cultural or linguistic backgrounds that differ from our own.

The next two sections of the book look in detail at the communicative issues that are specific to each developmental level from birth through adolescence and give assessment and intervention methods targeted for each level. The levels should be thought of as developmental rather than age-related. Because of developmental disabilities, children of widely varying ages could perform at any of these levels, so it is better to try to think of them as representing stages of functioning rather than chronological age. For this reason we have given them labels that do not refer to age.

Section II deals with development from birth to the point at which basic language skills are acquired. In the child language literature, the acquisition of these basic language skills is often indexed by stages introduced by Roger Brown (1973). We have labeled the end of this period with the highest of Brown's stages of early language development, Brown's Stage V. Essentially, this section covers the period of development that normally occurs between birth and the end of the preschool period, at about age 5. It includes information on what is usually considered "early" assessment and intervention and is divided into three periods: the "prelinguistic" stage (corresponding to the first year and a half of normal development), the "emerging language" stage (corresponding to developmental levels from 18-36 months), and the "developing language" phase (corresponding to developmental levels from 3-5 years). Again, though, some developmentally delayed clients who need the methods discussed in these sections will be older than preschool age.

Section III deals with children who have acquired basic oral language skills but have trouble with the linguistic demands of the academic curriculum. They will be at least school age; that is, older than 5 years, though not all clients older than 5 will have skills commensurate with this level. The section divides later language development into two broad periods: "language for learning," which comprises what normal children acquire during the elementary school years, and the "advanced language period," which deals with skills typically learned in adolescence and used in the secondary school curriculum.

Because such a large amount of information is covered in each chapter, we've tried to help students assimilate it by providing a study guide for each one. The guide essentially lists, in question form, all the major topics introduced in the chapter. For the information that is more or less factual, the questions ask you just to recall or review it. For portions of the chapter that are more

conceptual or debatable, the study guide encourages you to discuss or argue the issues. The point of the study guide is to supply an outline to use in reviewing the material in the chapter and to help you organize the information in your own mind. Answering the questions literally is not the most important goal. It's more fruitful to use the guide as a way of thinking back through all the issues raised in the chapter. Because studying this material often involves mastering concepts and understanding issues rather than memorizing facts, many students find that using the guides in study groups is more helpful than doing them alone. Suggested projects that can be used for class assignments are also included for each chapter at <http://evolve.elsevier.com/Paul/language/>.

In order to bring the discussion down from an abstract to a more concrete level, we've included many vignettes and case studies in the text to illustrate the points being made or to serve as examples of how the principles discussed in the book can be applied in real practice. All the vignettes and case studies are drawn from our own clinical experience, although they are usually embroidered to illustrate a particular point in a short time period. Their purpose is

to breathe some life into the text and to show how the methods can be integrated in working with a single child. As case studies, though, they are limited in scope and are not meant to represent the only way to implement the procedures in the text. They are just an example of one way. At <http://evolve.elsevier.com/Paul/language/> you will also find a video vignette to accompany each chapter and illustrate some of the points each makes.

Many of the problems that we've raised here—the youth of our field, its lack of a firmly established knowledge base, the fluidity of development that makes age a poor indicator of functioning level—can make the study of language disorders in children a daunting task to beginning clinicians. But these same problems are what make our field so fertile and exciting. There is so much to learn, so much room for growth and acquisition of new knowledge, and so much opportunity for each clinician to contribute unique information and develop innovative methods that really address children's needs. We hope you'll try, as you struggle through the sense of being overwhelmed that inevitably accompanies learning a lot of new things in a short time, to keep those possibilities in mind.

Acknowledgments

There are so many people whose help and encouragement made possible the completion of this book in its original form that I hesitate to begin naming them, for fear of being unable ever to complete the list. First, I must thank my colleagues at Portland State University, particularly Mary Gordon-Brannan, Ellen Reuler, Mary T. Withers, and Joan McMahon, for their unflagging willingness to “take up the slack” in department chores to allow me to concentrate on the writing. Second, I want to thank my teachers Carol Chomsky, Robin Chapman, Jon Miller, Larry Shriberg, and Jean Chall, who taught me most of what I know and how to learn the rest. I am deeply grateful to colleagues Linda Swank, Denise Rini, Althea Marshall, Wendy Marans, and Nancy Lebov, both for their love and encouragement and for the clinical insights they shared with me. Much appreciation goes to the people who reviewed early drafts of this work and provided insightful suggestions for revision, including Melanie Fried-Oken, Christine Dollaghan, Anne van Kleeck, and Pat Launer. I am grateful, too, to the students at Portland State University who struggled through early versions of the book and were so patient and accepting of its many imperfections. I am indebted, as well, to the assistants who worked on the first edition, Nicole Midford, Dave Andrews, Anne Cole, and John Hanlon. Thanks also to Brent Schauer and his staff at the PSU Graphic Arts Department for their help with figures and tables.

In preparing the fourth edition, I had invaluable help from Jessica Lewis, Nicole Benson, Carolyn Gosse, and Sarita Austin. Thanks also go to my colleagues Elizabeth Simmons and Megan Lyons. I am deeply grateful to Sandra Holley-Carter of Southern

Connecticut State University for making it possible for me to complete this edition back home in New England. To Fred Volkmar of the Yale Child Study Center go my deepest thanks his longstanding friendship and support. I thank my children, Will, Marty, and Aviva Isenberg, for coping so graciously with their working mother. Finally, I want to express gratitude to my late husband, Charles Isenberg, for the love he always gave so freely and the pride he took in all my endeavors.

—Rhea Paul

My thanks first and foremost to Rhea Paul, for inviting me to contribute to such a well-established and well-loved text. I have so valued the times we have spent working together on this edition, debating the issues and sharing our vision of the future of speech-language pathology. I have learned an enormous amount, not just about content but also about the process of synthesizing and distilling the information for our readership. For this amazing opportunity I am deeply honored.

I have been incredibly fortunate to work with and learn from some exceptional scholars in the field. I am forever grateful to Professor Dorothy Bishop at the University of Oxford, for taking a chance on a young speech and language therapist and supporting my career from its early foundations. She continues to be a trusted mentor and source of intellectual inspiration.

Finally, I thank Raymond and Rowan Norbury for their support and delight in my work and accomplishments, and for making the time between writing so enjoyable.

—Courtenay Norbury

Topics in Child Language Disorders

I

SECTION

CHAPTER

1

Models of Child Language Disorders

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Give a brief history of the field of developmental language disorders.
2. Discuss terminology to describe children's language-learning problems.
3. List the aspects and modalities of communication.
4. Discuss diagnostic issues that surround developmental language disorders.
5. Describe different methods used to investigate the biological bases of developmental language disorders.
6. Discuss comorbidity in developmental language disorders.
7. Summarize current theoretical models of developmental language disorders.

When one of us was a graduate student of speech-language pathology, circa 1977, in the course of a seminar in language disorders in children, one whole class session was spent debating just what was meant by *developmental language disorders* (DLD). After a good deal of discussion, it became clear that no one, including the professor, had a really good definition. Instead, most ways of defining it came down to saying what it was not. The disgruntled students were shocked and confronted the professor in dismay: "You mean we've spent this whole term talking about something, and you don't even know what it is?"

Perhaps even more surprising is that some 30 years later, on a different continent, the other of us was engaged in a similar debate. And even today, after all of the advances in our understanding of the underlying architectures and mechanisms that support language development, we are still no nearer a clear consensus on what developmental language disorders are, how they should be defined, or even what they should be called!

The complexities surrounding DLD are illustrated by Jamie's story.

When 6-year-old Jamie was referred for assessment in September, the school's speech-language pathologist (SLP), Ms. Reese, conducted an intensive assessment and reported that Jamie was functioning at the level of a 4-year-old in terms of his expressive and receptive language abilities. The school psychologist also tested Jamie and reported that his nonverbal skills (as measured by a standard IQ test) were borderline, not low enough to be identified as globally delayed or to warrant placement in a special classroom. Ms. Reese therefore decided to include Jamie in her caseload because her testing clearly indicated that his language skills were below the level expected for his chronological age.

Ms. Reese moved to a different school in October and Mr. Timmons took over her caseload. He reviewed Ms. Reese's assessment records and the school psychologist's report. He concluded that Jamie was functioning at the level expected given his mental age, which the school psychologist reported as 4 years 2 months. Mr. Timmons therefore dropped Jamie from the caseload and put him on monitoring status.

Who's right? Does Jamie have a language problem, or doesn't he? Even his speech-language pathologist can't decide, yet determining who is eligible for services is one of the major functions of the SLP. What goes into making this decision?

DIAGNOSTIC ISSUES IN DEVELOPMENTAL LANGUAGE DISORDERS

The American Speech-Language and Hearing Association (ASHA) has defined language disorder as an impairment in "comprehension and/or use of a spoken, written and/or other symbol system. The disorder may involve (1) the form of language (phonology, morphology and syntax), (2) the content of language (semantics)

and/or (3) the function of language in communication (pragmatics), in any combination” (1993, p. 40).

This definition assumes a *naturalist* perspective (Tomblin, 2008), in which impairment is characterized as a deviation from the average level of ability achieved by a similar group of people. In this case it is useful because it covers a broad range of language behaviors across different modalities. However, it does not help the clinician decide what differences in language behavior constitute an impairment or at what level of impairment intervention is warranted. In Jamie’s case we might ask, should the decision be based on deviation from chronological age expectations, or overall level of cognitive ability? How far behind does a child’s language need to be to warrant intervention? Is an isolated impairment in one aspect of language as serious as a more mild impairment across a range of language skills?

Instead of worrying about absolute level of language impairment, we could ask about the *impact* of the language impairment on the child’s overall development and ability to function in everyday situations. Tomblin (2008) refers to this as a *normative* perspective, which takes into account society’s values and expectations concerning individual behavior. He states that “a language disorder exists when the child’s level of language achievement results in an unacceptable level of risk for undesirable outcomes” (p. 95). In other words, a language disorder should only be diagnosed when it interferes with the child’s ability to meet societal expectations now or in the future. This could include difficulties with social relationships, academic achievement, and future employment prospects.

Such a definition is neutral regarding the causes of the language impairment; instead, it focuses on those language behaviors that increase risk for adverse outcomes. But how do we identify the level of language impairment that incurs the greatest risk of poor outcome? And how do we measure the impact of language impairment on the child’s everyday activities?

You probably won’t be surprised to hear that there is little consensus in the field about how best to resolve these issues. You might be more surprised to hear that there is also little consensus about the terms we use to describe these disorders, yet this clearly has an impact on the public awareness of and provisions for developmental language disorders (Bishop, 2010).

A BRIEF HISTORY OF THE FIELD OF LANGUAGE PATHOLOGY

Descriptions of a syndrome of disorders of language learning in children date back to the early nineteenth century to the late eighteenth century (see de Montfort Supple, 2010; Stark, 2010 for more comprehensive reviews). Gall (1825) was one of the first to describe children with poor understanding and use of speech and to differentiate them from those with intellectual disability (ID). Subsequently, a great many discoveries about the relations between the brain and language behavior in adults were made by neurologists such as Broca (1861) and Wernicke (1874). The disorders Gall first identified were thought to be parallel to the aphasias these neurologists were studying in adults. For the first century of the existence of the study of language learning and its disorders, neurologists dominated the field, focusing attention on the physiological substrate of language behavior.

The neurologist Samuel T. Orton (1937) can perhaps be thought of as the father of the modern practice of child language disorders. He emphasized the importance not only of neurological but also of behavioral descriptions of the syndrome and pointed out the connections between disorders of language learning and difficulties in the

acquisition of reading and writing. In the 1940s and 1950s, other medical professionals, such as psychiatrists and pediatricians, took an interest in children who seemed to be unable to learn language but did not have mental retardation or deafness. Gesell and Amatruda (1947) were pioneers in developmental pediatrics; they devised innovative techniques for evaluating language development and recognized the condition they called “infantile aphasia.” Benton (1959, 1964) provided the fullest descriptions of children with this syndrome and is credited with evolving the concept of a specific disorder of language learning that is structured by excluding other syndromes, such as autism, deafness, and intellectual disorders, rather than by parallels to adult aphasia.

At about the same time as these medical practitioners were refining notions of language disorders, another group of workers also was advancing concepts about children who failed to learn language. Ewing (1930); McGinnis, Kleffner, and Goldstein (1956); and Myklebust (1954, 1971) were all educators of the deaf and, as such, had developed a variety of techniques for teaching language to children who did not talk or hear. They all noticed that some deaf children’s language skills were worse than could be expected on the basis of their hearing impairment alone. This observation led them to focus more interest on the language impairment itself and to attempt to develop more effective methods of remediation for children who did not succeed with the standard approaches that were used to teach language to other children with hearing impairments.

However, until the 1950s, no unified field of endeavor addressed the problems of the language-learning child; considered these problems to be disorders of language itself, rather than a result of some other syndrome (deafness, for example); or treated language disorder in children regardless of its cause. Aram and Nation (1982) give credit to three individuals for developing this new field: Mildred A. McGinnis, Helmer R. Myklebust, and Muriel E. Morley. These pioneers integrated the information currently available on language disorders in deaf and “aphasic” children and devised educational approaches that could be used to remediate the language dysfunctions demonstrated by these children.

McGinnis (1963) developed the “association method” for teaching language to “aphasic” children. This method was very influential in the development of the field of language disorders, providing the first highly structured, comprehensive approach to language intervention. McGinnis also was one of the first to distinguish between two types of language problems seen in children: what she called expressive, or motor, aphasia (what we today would call *expressive language disorder*) and receptive, or sensory, aphasia (what we would term *receptive language disorder*).

Morley (1957) was instrumental in applying information on normal language development to the problem of treating children with a language disorder and was one of the first individuals from a speech pathology background to push language and its disorders into the purview of the “speech therapist.” She fostered the use of detailed descriptions of children’s language behavior in making diagnoses and planning intervention programs. She also was important in providing definitions that allowed clinicians to distinguish language disorders from articulation disorders.

Myklebust (1954) went, perhaps, the furthest in establishing a new and distinct field of study and practice, which he dubbed “language pathology.” Like Morley and McGinnis, he was interested in differential diagnosis. He developed schemes for classifying language disorders in children, which he called “auditory disorders,” and for differentiating them from deafness and ID. But Myklebust, like Orton, was also concerned with the continuities between disorders of oral language acquisition and their consequences for

the acquisition of literacy skills. In founding the new discipline of language pathology, Myklebust pointed the way toward considering language disorders in this broad context, including difficulties not only in producing and comprehending oral language but also in the use of written forms of language.

At about the same time that the field of language pathology was being established, the study of language itself was being revolutionized by the introduction of Chomsky's (1957) theory of transformational grammar. This innovation led to an explosion in research on child language acquisition that the new discipline could use. In the 1960s and 1970s, as child language research expanded in focus from syntax to semantics to pragmatics and phonology, language pathology followed in its footsteps, broadening our view of the relevant aspects of language that needed to be described and addressed in clinical practice. The vast amount of new information on normal development being compiled made it possible for language pathologists to describe a child's language behavior in great detail and to make specific comparisons to normal development on a variety of forms and functions. Furthermore, the large database on normal acquisition provided a blueprint of the language development process that could serve as a curriculum guide for planning intervention. This possibility has greatly influenced how language pathology is conceptualized and practiced today. Stark (2010) provides a history of language pathology from this period to the beginning of the current century.

As the twentieth century drew to a close, rapid developments in our understanding of genetics and our ability to study brain structure and function greatly enriched the field of language pathology. It has become increasingly clear from family and twin studies that genetic factors exert a strong influence on language development and disorders (Bishop, 2009). However, it is equally clear that we are unlikely to discover a "gene for language" (Box 1-1). Instead, it is probable that multiple genes of small effect alter the way the brain develops in subtle but important ways, rendering the developmental path from genes to brain to behavior extremely complex and difficult to predict (Fisher, 2006). In addition, we now know that children with language impairments in the absence of other syndromes do not have obvious neurological lesions that could explain their language difficulty. In fact, we now know that children with early focal brain lesions rarely have long term deficits in language learning (Bates, 2004). This realization has led to some changes in the terminology we use to label language difficulties in children.

Young children with DLD are sometimes labeled "language delayed."

BOX 1-1 Is There a Gene for Language?

In 2001, researchers in the UK discovered a single gene mutation that caused a severe speech and language disorder in members of a three-generation family (Lai, Fisher, Hurst, Vargha-Khadem, & Monaco, 2001). This caused much speculation in the media that the gene, *FOXP2*, was a "gene for language." You will have realised by now that genes do not directly encode behavior and so we can't really talk about a gene for language (or a gene for reading, autism, obesity, etc.; see <http://deevybee.blogspot.com/2010/09/genes-for-optimism-dyslexia-and-obesity.html> for a detailed discussion). Instead, *FOXP2* is better thought of as a "chief executive officer" (Marcus & Fisher, 2003) regulating the behavior of other genes (see Fisher & Scharff, 2010 for review). *FOXP2* is expressed in the brain, in regions that are important for speech and language and in regions that are atypical in affected members of the KE family (Watkins et al., 2002). These areas include the caudate nucleus, putamen, cerebellum, temporal cortex, inferior frontal gyrus, and motor cortex, suggesting that the gene product is particularly crucial for the development of motor systems in the brain. This suggestion is consistent with the behavioral phenotype of the KE family, which includes a marked verbal dyspraxia, in addition to impairments in vocabulary and grammar. More recent studies have confirmed the role of *FOXP2* mutations in disorders that include aspects of verbal dyspraxia (Feuk et al., 2006; MacDermot et al., 2005; Zeesman et al., 2006). At the same time, *FOXP2* does not appear to be implicated in more common forms of DLD (Newbury et al., 2002; O'Brien et al., 2003; SLI Consortium, 2004), and the pattern of inheritance seen in more common forms of DLD is inconsistent with a single-gene disorder.

It is also interesting to note that *FOXP2* is expressed in other body tissues such as the heart, lungs, and gut and is also expressed in other species, such as song birds and mice. Although we've yet to see a talking mouse, it does appear that mice bred to have mutations of *FOXP2* produce fewer innate ultrasonic vocalisations (Fujita et al., 2008) while in song birds it has been reported that reducing the expression of *FOXP2* can disrupt song learning (Haesler et al., 2004). These finds have generated considerable debate about the role of *FOXP2* in speech and language disorders. Is it important for the development of motor skills that support language production? Or is it more important for learning and synaptic plasticity (see Fisher & Scharff, 2009 for a detailed discussion)? Answers to these questions will require in-depth study of the neurobiological pathways of *FOXP2* and its downstream targets (Newbury et al., 2010).

TERMINOLOGY

Speech, Language and Communication

A first question might be "why do we use the separate terms *speech*, *language*, and *communication* when a single word label might be preferable?" The answer is that the three do not always go together, although impairments in one area may well influence development or competencies in another. For instance, a child with a speech sound disorder typically produces a restricted range of speech sounds, rendering spoken output unintelligible. This is likely to affect the ability to communicate, as conversational partners may not always understand the intended meaning. Nevertheless, the child may have normal language skills, understanding what others

Some children with DLD have appropriate communication skills.

say and using grammatically complex sentences. He or she may also have a typical drive to communicate, supplementing impaired speech with gestures and reformulating spoken output order to be understood.

A child with a language disorder may not have difficulties producing speech sounds, but his ability to communicate may be limited by his poor understanding of what others say to him, by his limited vocabulary and his reliance on simple and immature sentences. However, he may still use these limited language skills to share his thoughts and experiences with other people. In contrast, some children have perfect articulation, exceptional vocabularies, and can express themselves using long and grammatically complex sentences; yet their communication skills are limited by odd and tangential speech, repetitive language, and a reduced ability to repair breakdowns in conversation, as in the case of some children with autism spectrum disorders (ASD). Thus researchers and practitioners often make a distinction between the three in order to highlight the child's most salient difficulty.

What's in a Name?

Very often, speech, language, and communication impairments occur in the context of another developmental disorder with a recognized label, for example, ASD or Down syndrome (see Chapter 4). In these cases, descriptive terms such as *speech*, *language*, and *communication impairment* are very helpful in identifying the strengths and weaknesses of a child's communication profile. However, when impairments are not associated with a more pervasive disorder, we seem to struggle to label them in a way that conveys a child's needs or that the wider public readily recognizes and understands. This issue was highlighted by Kahmi (2004) who wondered why, unlike autism and dyslexia, "no one other than speech-language pathologists and related professionals seems to know what a language disorder is" (p. 105).

One possible reason for this is that there are a variety of names given to the problems we have been discussing, including *specific language impairment*, *language delay*, *language disability*, *language disorder*, or *developmental language disorder*. In addition, the terms we use have changed considerably over time, while other diagnostic terms (such as dyslexia) have remained relatively stable. For instance, the term *congenital aphasia* (from the Greek word

aphatos, meaning "speechless") was first used in 1866 (de Monfort Supple, 2010), gradually becoming "developmental aphasia" or "dysphasia," terms popular until the mid-twentieth century. These terms had their foundations in adult neuropsychology and referred specifically to loss of language ability following brain damage; when it became clear that developmental language disorders did not arise from similar neurological insults, these terms became less fashionable. The notion that language could be impaired in the context of "spared" capacities in other aspects of development led to labels such as *specific language impairment* (SLI) replacing *dysphasia*, at least in the research literature. But that is a mouthful and still suggests that deficits are restricted to speech, language, and communication. That is clearly not always (and indeed, many would argue, rarely) the case. In clinical practice, it is not uncommon to find practitioners describing language *difficulties* or *delays*, particularly with young children. This stems from a recognition that some children are "late bloomers" as far as language development is concerned; they generally catch up after a late start in learning to talk, and we can't assume an underlying pathology in such cases. Still, a large body of research suggests that even late talkers who seem to catch up with peers often continue to show subtle weaknesses in language function (Rescorla, 2009). For all these reasons, we will use a term in this book that we believe is more neutral and descriptive than the others we have mentioned. We use the term *developmental language disorder* to describe children who are not acquiring language as would be expected for their chronological age, for whatever reason.

Throughout this book, then, we highlight three groups of children who together will form the bulk of the SLP caseload:

1. Children with *primary* DLD, for whom language impairments are the most salient presenting challenge, for whom the biological cause of disorder is not yet known, and for whom no other diagnostic label is appropriate. The most recent version of the Diagnostic and Statistical Manual of the American Psychiatric Association (DSM-V; APA, 2012) uses the term *language impaired* to refer to this group.
2. Children of school age with primary DLDs that co-exist with *literacy disorders* (dyslexia and poor reading comprehension), whom we will refer to as having *language-learning disorders* to call attention to the consequences of their difficulties on academic achievement. We will focus on these children in Section III of this book.
3. Children with DLDs that are associated with or secondary to some other developmental disorder such as ASD or intellectual impairment (ID). We will discuss many of the syndromes that are often accompanied by DLD in Chapter 4.

Now that we have agreed what to call it, we need to decide when a child would qualify for a diagnosis of developmental language disorder. It might help to consider the components of our label: *developmental* indicates that a problem arises in childhood, *language* refers to the code we use to communicate, and *disorder* suggests a significant deviation from the typical developmental trajectory. Simple, right? Well, not exactly. One issue is that *developmental* also suggests a changeable target—a 4-year-old with language disorder will look quite different from a 14-year-old with language disorder, and the challenges each needs to overcome will require very different approaches. A second issue is that *language* itself is a multi-faceted and highly interactive system that can be conveyed in different modalities, for example, spoken language or written text. Which aspects and modalities should we assess and what should we prioritize for treatment? Finally, as we've already

highlighted, in a behaviorally defined *disorder*, the point at which a problem becomes a *significant* deviation from normality is often an arbitrary decision. What factors go in to making this decision? Let's take a look.

ASPECTS AND MODALITIES OF LANGUAGE DISORDER

Bloom and Lahey (1978) and Lahey (1988) provided a useful framework for exploring language competencies that has stood the test of time. They suggested that language is comprised of three major aspects, illustrated in Figure 1-1:

1. *Form*: including syntax, morphology, and phonology
2. *Content*: essentially consisting of semantic components of language, vocabulary knowledge, and knowledge of objects and events
3. *Use*: the realm of pragmatics, or the ability to use language in context for social purposes.

Below is an outline of the key linguistic characteristics of DLD with respect to *form*, *content*, and *use* (summarized in Table 1-1). Not all of these features will be present in all children with a diagnosis of DLD and the features that characterize a child at one age may be very different to the features that stand out as that child gets older. Let's look at these features in a little more detail.

Form

Deficits in grammar are hallmarks of primary DLD. While many grammatical deficits occur in the context of weak phonology and semantics, it may also be possible for grammatical deficits to occur in isolation (van der Lely, 2005). The most consistently reported finding is that young children with primary DLD omit morphosyntactic markers of grammatical tense in spontaneous speech where these morphemes are obligatory. These errors include omission of past tense *-ed* ("He walk__ to school yesterday"), third person singular *-s*

("She walk__ to school everyday"), and the copular form of the verb *be* ("I eating chocolate") (Rice, Wexler, & Cleave, 1995). An important observation is that these are errors of omission, not commission (Bishop, 1994); in other words children do not confuse tenses and morphemes. These grammatical forms are typically acquired by the age of 5, therefore persistent errors in older children is a sensitive indicator of language impairment. Older children with DLD have problems producing *wh-* questions (van der Lely & Battell, 2003), may omit obligatory verb arguments ("the woman is placing on the saucepan"), and use fewer verb alternations ("the girl is opening the door" versus "the door is opening") (Thoradottir & Weismer, 2002). These deficits in production are matched by problems in making grammaticality judgments (Rice, Hoffman, & Wexler, 2009) and in understanding complex syntax. For instance, children with DLD have poor understanding of passive constructions ("the boy was kissed by the girl"), embedded clauses ("the boy chasing the horse is fat"), pronominal reference (e.g., knowing who "him" refers to in the sentence "Mickey Mouse says Donald Duck is tickling him"), locatives ("the apple is on the napkin") and datives ("give the pig the goat") (Bishop, 1979; van der Lely & Harris, 1990).

Although grammatical errors are a striking feature of DLD, it is not the case that children with DLD completely lack grammatical knowledge. Instead, children are inconsistent in their application of this knowledge, behaving as if certain grammatical rules were "optional" (Bishop, 1994; Rice et al., 1995). If children lacked knowledge, on formal tests of grammatical understanding we would expect either a systematic response bias (i.e., always interpreting a passive sentence such as "the boy was kissed by the girl" by word order "boy kiss girl") or random guessing. In fact, performance on grammatical tests is typically above chance levels, even when non-syntactic strategies to support understanding are not evident. This suggests that factors other than grammatical knowledge influence performance, a hypothesis supported by the finding that grammatical errors may be induced in typically developing individuals by increasing processing demands (Hayiou-Thomas, Bishop, & Plunkett, 2004).

Phonological deficits are frequently described in terms of a child's repertoire of available speech sounds and the consistent error patterns a child uses in speech. An epidemiological study of 6-year-olds in the United States found the prevalence of speech sound disorders (SSD) to be 3.8% with a co-occurrence of SSD and language impairments of 1.3% (Shriberg, Tomblin, & McSweeney, 1999). Problems with speech production are likely to be more prevalent in clinically referred samples, perhaps because they are more readily identified by parents and teachers (Bishop & Hayiou-Thomas, 2008).

For the most part, phonological impairments do not have a physical basis. Instead, these deficits arise from problems with phonological processing. Phonological processing encompasses a range of behaviors, including the ability to discriminate and categorize speech sounds, produce speech sounds and meaningful phonemic contrasts, remember novel sequences of speech sounds, and manipulate the sounds of the language. Children with DLD may therefore fail to recognize which sounds are important for signalling meaning in the language, with implications for vocabulary and grammatical development.

Content

Children with DLD tend to have impoverished vocabularies throughout development (Beitchman et al., 2008), but their semantic difficulties extend beyond the number of words available to

FIGURE 1-1 Bloom and Lahey's taxonomy of language. (Adapted from Lahey, M. [1988]. *Language disorders and language development*. New York: Macmillan.)

TABLE 1-1 Common Linguistic Characteristics of Primary DLD

Form	Errors in speech production and poor phonological awareness; i.e., the ability to manipulate sounds of the language, particularly in the preschool years. Errors in marking grammatical tense, specifically the omission of past-tense –ed and third person singular –s, as well as omission of copular “is,” and errors in case assignment (e.g., “Him run to school yesterday”). Simplified grammatical structures and errors in complex grammar, for example, poor understanding/use of passive constructions (“the boy was kissed by the girl”), wh- questions, dative constructions (“the boy is giving the girl the present”)
Content	Delayed acquisition of first words and phrases Restricted vocabulary and/or problems finding the right word for known objects, for example uses the word “thing” for most common objects
Use	Difficulties understanding complex language and long stretches of discourse Difficulties telling a coherent narrative Difficulties understanding abstract and ambiguous language

Note: number of symptoms present in any one child is variable and profile of language impairment may change over time.

them. In general, children with DLD are slow to learn new words, have difficulty retaining new word labels, encode fewer semantic features of newly learned items, and require more exposure to novel words in order to learn them (Alt, Plante, & Creusere, 2004). Children with DLD often make naming errors for words they do know, for instance, labelling “scissors” as “knife” or using less specific language such as “cutting things.” As children get older, the problem may not be how many words the child knows, but what the child knows about those words. For instance, children with DLD may not realize that words can have more than one meaning, for example that “cold” can refer to the temperature outside, an illness, or a personal quality of unfriendliness. This lack of flexible word knowledge may account for reported difficulties in understanding jokes, figurative language, and metaphorical language, all of which draw on in-depth knowledge of semantic properties of words, and how words relate to one another (Norbury, 2004). Finally, there is some indication that learning about verbs may be a particular source of difficulty for children with DLD (Riches, Tomasello, & Conti-Ramsden, 2005). Problems acquiring verbs may have implications for learning about sentence structure because of the unique role verbs have in determining other sentence constituents (arguments) and in signalling grammatical tense.

Use

Pragmatics is commonly associated with the notion of “social communication,” which encompasses formal pragmatic rules, social inferencing, and social interaction (Adams, 2008). In general, pragmatic skills of children with primary DLD are considered to be immature rather than qualitatively abnormal, as in the case of autism. In addition, although they perform more poorly than age-matched peers on various measures of social understanding, their difficulties are rarely as severe as those seen in autism. Nevertheless, children with DLD may have difficulties understanding and applying pragmatic rules. In conversation these may include initiating and maintaining conversational topics, requesting and providing clarification, turn-taking, and matching communication style to the social context. Children with DLD may be impaired relative to peers in their understanding of other minds (Farrar et al., 2009) and in understanding emotion from a situational context (Spackman, Fujiki, & Brinton, 2006). Individuals with DLD also have difficulties integrating language and context, resulting in difficulties generating inferences about implicit information in discourse (Adams, Clarke, & Haynes, 2009), understanding figurative

language (Norbury, 2004) and constructing coherent narratives (Reed, Patchell, Coggins, & Hand, 2007).

Chapman (1992), Miller (1981), and Miller and Paul (1995) talked about language in terms of its two primary modalities—comprehension and production—integrating each of the three aspects previously listed within these two modalities. From their viewpoint, *language disorders* would be defined according to the modalities primarily affected; the aspects or domains affected within these modalities are used to describe the language disorder once it is identified. But whether it is the domains and their interactions or the modalities of language that are used to define disorders, the important point is that disorders be defined broadly. We certainly want to be able to identify clients who fit the traditional idea of a child with a DLD (the one who has trouble learning to put words together to make sentences), but we also want to be able to identify and, therefore, help the child like Tommy, who is described in the following text.

Tommy was a very easy baby. His mother remembers that he was happy to lie in his crib for hours on end, watching his mobile. By age 2 Tommy was using long, complicated sentences and knew the name of every model of vehicle on the road, as well as the names of most of the parts of their engines. At age 4 he took apart the family lawn mower and put it back together. However, his preschool teacher was concerned about him. He took almost no interest in the other children, choosing, when he spoke, to speak only to adults. When he did talk, he invariably asked complex but inappropriate questions on his few topics of interest, such as mechanical objects. He dwelled incessantly on a few events that were of great importance to him, such as the time the doors of the family car would not open. Tommy seemed very bright in many ways and did well on an IQ test that was part of his kindergarten screening. But in social settings, he just did not know how to relate, and his language was used primarily to talk about his own preoccupations rather than real interactions.

Tommy might be considered a child with high-functioning ASD syndrome (see Chapter 4), but the primary manifestation of his disorder is in social communication, not in the understanding or production of sounds, words, or sentences. It is important that a definition of *language disorder* allow a child such as Tommy to qualify for services, even though his problem is confined to the use

of language for communicative purposes, with formal aspects of language relatively unaffected.

DIAGNOSTIC ISSUES

DLD Relative to What?

One way to describe children with developmental disabilities is to say that their developmental level is significantly lower than their chronological age. (This description is by no means complete; other conditions are necessary for a child to be diagnosed as having intellectual disability, for example.) Mental age is an index of developmental level; it is an age-equivalent score derived from a standardized measure of cognitive ability.

In talking about mental age for children with DLD, we try to use cognitive tests that do not involve the production or understanding of speech, or that do so as little as possible. We do not want to evaluate the cognitive ability of children with DLD on the basis of their language abilities. We already know that these children's language skills are not likely to be very good or they would not have been referred in the first place. Most intelligence tests use language-based items extensively, because in normal development, language and general intellectual level are very highly related. But some tests of cognitive skill are designed to assess aspects of thinking and problem solving that minimize the involvement of language.

Why might we want to use mental age, rather than chronological age, as a reference point to decide whether a child has a language disorder? For one thing, we usually would not expect a child's language skills to be better than the general level of development. Should a child functioning at a 3-year-old level overall be expected to achieve language skills commensurate with his chronological age of 8 years? Miller (1981) suggests that language level very rarely exceeds nonverbal cognitive level in the developmentally delayed population, even though the relationships between language and cognition are more complex and variable in normal development (Krassowski & Plante, 1997; Miller, Chapman, Branston, & Reichle, 1980; Notari, Cole, & Mills, 1992; Rice, Warren, & Betz, 2005).

But criteria for disability that are based on discrepancies between scores on IQ and other tests are no longer thought to be valid. Lahey (1990) was perhaps the first in the field of language pathology to stake out a position against mental-age referencing. She pointed out that many psychometric problems are associated with measuring mental age. For one, it is not psychometrically acceptable to compare age scores derived from different tests of language and cognition that were not constructed to be comparable, were not standardized on the same populations, and may not have similar standard errors of measurement or ranges of variability (see Chapter 2). Second, there are fundamental problems in using age-equivalent scores at all to determine whether a child's score falls outside the normal range. These issues are discussed further in Chapter 2. Lahey also emphasized the theoretical difficulties of assessing nonverbal cognition, centering her argument on the justification for deciding which of the many possible aspects of nonlinguistic cognition ought to be the standard of comparison. For all of these reasons, Lahey suggested that chronological age is the most reliably measured benchmark against which to reference language skill to identify language disorders.

Remember Jamie? The two clinicians involved in his case differed on precisely this point. But ASHA (2000a) argued strongly against "cognitive-referencing" in making decisions about eligibility

for services. A major criticism is that different combinations of tests can yield different eligibility recommendations for the same student. How can this be? Often, young children with DLD show an uneven language profile, with severe deficits in morphology and syntax and relative strengths in vocabulary knowledge (Abbeduto & Boudreau, 2004; Rice, 2000, 2004). Therefore, we might expect vocabulary scores to be more in line with nonverbal IQ scores, while tests of morphosyntax might result in a very large discrepancy. A second criticism is that longitudinal studies of children with language disorders have reported a drop in nonverbal IQ scores over time (Botting, 2005; Stothard, Snowling, Bishop, Chipchase, & Kaplan, 1998). It is unlikely that this reflects an actual loss in ability; rather it shows that nonverbal assessments are rarely "pure" measures of nonverbal ability. The majority of nonverbal tests incorporate verbal directions, and many linguistically able children use verbal strategies to help them reason out the answers. This puts the child with DLD at a distinct disadvantage. Third, the degree of discrepancy between verbal and nonverbal abilities does not necessarily predict a child's responsiveness to intervention. Research has shown that children with generally depressed nonverbal scores can still benefit from therapy (Fey, Long, & Cleave, 1994). Finally, a categorical denial of services to children because of generally depressed nonverbal IQ scores is not consistent with the ethos of the Individuals with Disabilities Education Act (IDEA Amendments of 1997, Public Law 105-17), which stipulates that services be determined on an individual basis (Whitmire, 2000a).

But even if we do not use mental age—based discrepancy criteria to identify children with language disorders, mental age still provides us with some guidelines to help in determining the goals of intervention. By getting a general idea of a child's developmental level, through standardized tests as well as through instruments that measure adaptive behavior, we can determine what behaviors are reasonable to target in an intervention program. We would not expect a child with ID, for example, to work on language goals appropriate for his or her chronological age, even if that age were used as the reference point to identify the need for language intervention. Instead, we would want to evaluate at what level the child is functioning currently and target language behaviors closer to overall developmental level.

Are There Subtypes of DLD?

Clearly there are many different ways that language may be impaired, which raises the question of whether there are subtypes of DLD. For example, van der Lely (2005) describes children with "grammatical-SLI," in which grammatical skills are more severely impaired relative to other aspects of the language system. In addition, there has been considerable debate in the literature regarding the diagnostic status of children with "pragmatic language impairments," or PLI, and whether they are continuous with more specific language impairments or autism (cf. Whitehouse, Watt, Line, & Bishop, 2009). Nosologies for "subtypes" of language disorder have been used for a number of years (cf. Conti-Ramsden et al., 1999; Rapin and Allen, 1987), but are they useful constructs?

One assumption here is that the biological mechanisms that give rise to a particular subgroup, "G-SLI" for example, differ from those that give rise to other types of language difficulty. At the moment there is simply insufficient evidence that this is the case. A second concern is that these nosologies rarely take development into account. Longitudinal studies have demonstrated that although subgroups appear to exist throughout the school years, the

children that make up those subgroups move fluidly between them over time (Conti-Ramsden et al., 1999; Tomblin et al., 2003). In other words, children may start off with a predominantly lexical-syntactic pattern of language disorder, but, as they grow older, may more closely resemble children with pragmatic language concerns. Information about very young children who go on to have “G-SLI” is lacking; we therefore don’t know if these children are characterized by more pervasive language, perceptual, or cognitive deficits at earlier developmental time points. In other words, while the presence of a language disorder tends to be stable over time, the nature of that language disorder is very likely to change.

How Low Can You Go?

A central tenet of the naturalist perspective held by Tomblin (2008) that we discussed earlier is that impairment can be defined as deviation from average performance. Standardized tests fulfil this role nicely; they measure a set of skills in a large number of children drawn from the general population and set normative scores based on the average performance of those children. This enables us to compare an individual child’s performance against the average abilities of his or her peer group. However, where we set the cut-off for significant deviation from the average is entirely arbitrary; in medical diagnoses, the “normal” range is often taken to be scores within two standard deviations (SDs) of the mean, which encompasses 95% of the population (see Chapter 2). A naturalist might therefore diagnose children scoring more than 2 SD below the mean (i.e., the third percentile and below) with DLD.

While this would not be an unreasonable approach, there are a number of issues with it. First, children with DLD often have uneven profiles of language skill and deficit. Remember Jamie? If we gave him ten tests tapping different aspects of language and he only achieved a “deviant” score on one of those tests, would that constitute a DLD? On the other hand, Jamie might score between -1 and -2 SDs on 9 of those 10 tests. If we stick rigidly to our -2 SDs cut-off Jamie would not meet criteria for DLD and yet might have considerable difficulty coping in everyday situations.

In some agencies or school districts, cut-off scores for eligibility for services are mandated and the clinician must abide by them, having leeway only in choosing which instruments to use to measure performance. In other cases, this decision is made on the basis of caseload considerations. For example, if a clinician were to accept into the caseload all the children who scored more than 1 SD below the mean on a single standardized test (approximately 16% of the population), the result might be chaos and rapid burn out. On the other hand, sticking rigidly to the -2 SDs cut-off would serve only about 3% of the population, limiting access to support for children who may really need it. Often, researchers and clinicians inhabit the middle ground and consider those children scoring in the bottom 10th percentile (equivalent to a standard score of 80, or -1.25 SDs below the normative mean) to have DLD.

Is there any empirical evidence to support this middle ground? In an epidemiological sample, Tomblin and colleagues (Tomblin, 2010; see also www.uiowa.edu/~clrc/epidemiologic/index.html) used a battery of tests that tapped three language domains (vocabulary, grammar, and narrative) in two modalities (production and comprehension), yielding five composite scores. They diagnosed primary DLD at school entry if at least two of the five composite scores were more than -1.25 SD (10th percentile), the standard score on a nonverbal intelligence test was 87 or greater, and the child met typical exclusionary criteria. In a population sample,

this resulted in 0.85 sensitivity (ability to identify true cases of disorder) and 0.99 specificity (ability to correctly identify unimpaired cases), yielding a prevalence estimate of 7.4%. Three points about this study are noteworthy. First, the overall degree of impairment required by these authors was fairly lenient (overall severity of -1.12 SD), and therefore may have included children with more transient language delays. Indeed, 46% of children identified by Tomblin et al. as having DLD at school entry did not meet diagnostic criteria for DLD a year later, suggesting these criteria identify a large number of false positives (Tomblin et al., 2003). Second, an intriguing finding from this study was that only 29% of children who met the research criteria for DLD had been identified by parents or practitioners as having language difficulties. Even if more stringent severity criteria were employed to include only those children with composite language scores of -2 SDs or greater, the percentage of children clinically referred for language difficulties only rose to 39%. This suggests that the features that lead to identification of DLD in everyday circumstances may be different from those identified by standardized tests (Bishop & Hayiou-Thomas, 2008). Third, the assessment battery did not include measures of phonological skill or pragmatic ability; deficits in these areas may also negatively impact educational and/or social development. Interestingly, Bishop and Hayiou-Thomas (2008) reported that in a population sample of twins with DLD, children referred for speech-language evaluation were more likely than the others to have phonological processing deficits. Thus, inclusion of phonological measures in diagnostic batteries may increase concordance between population and clinical samples.

What Is the Impact of Language Disorders on Daily Living?

Standardized test scores can give us some useful information about a child’s abilities relative to his or her peers. But sometimes we may need to go beyond the standard score in determining whether or not speech-language services are required. Why is that? To begin with, tests with adequate psychometric properties (such as validity; standard error of measurement; and large, representative norming samples) are not always available for testing at all age levels, for all language communities, or for all aspects of language and communication. For instance, measuring pragmatic language abilities is notoriously difficult (Adams, 2002), in large part because pragmatic skills are so context dependent. Thus, any attempt to structure and standardize the context removes a large degree of the challenge. In addition, although the situation is improving, many of our standardized instruments are culturally and linguistically biased, putting children from less mainstream cultural backgrounds at a disadvantage. One solution is to develop tests that are not reliant on cultural or linguistic knowledge and instead assess the ability to “process” novel information, such as a non-word repetition task. While these tasks reliably distinguish language difference from language disorder (Rodehor & Haynes, 2001; Windsor, Kohnert, Lobitz, & Pham, 2010), they do not provide the clinician with a picture of the child’s linguistic capabilities, making them of limited use in intervention planning. Thus, in some situations, age-appropriate scores on a standardized test may occur even when the child is having significant difficulty communicating in everyday situations. On the other hand, sometimes children obtain lower than expected scores on a test, yet their communicative skills are very much in line with other individuals from their cultural background.

The *normative* position advocated by Tomblin (2008) stresses that language disorders must involve a significant deficit relative, in part, to *environmental expectations*. In common-sense terms, that means a deficit big enough to be noticed by ordinary people such as parents and teachers—not just language development experts—and one that affects how the child functions socially or academically in his or her immediate environment. The impairment, in other words, has to have some adaptive consequences. One challenge for this perspective is that certain types of language impairment are more readily apparent to non-specialists. For example, children referred for professional assessment are more likely to have overt difficulties with speech sounds or immaturities in expressive language; (Bishop & Hayiou-Thomas, 2008; Zhang and Tomblin, 2000). Subtle problems with language comprehension may be more easily missed; however, these subtle difficulties may manifest in poor scholastic attainment, social difficulties, or behavioral problems. On the other hand, children may achieve low scores on formal tests of language and yet not incur any disadvantage in daily life. For these children, it may not be prudent to intervene.

Diagnostic frameworks such as DSM-V (APA, 2012) and the World Health Organization International Classification of Disease—10 (WHO, 2004) stress the importance of evaluating the *impact* of disorder on everyday well-being, although standard methods of assessing this impact are not well developed in the area of children's language. One method for systematically considering

impact is offered by the *International Classification of Functioning, Disability and Health* (WHO, 2001; www.who.int/classifications/icf/training/icfbeginnersguide.pdf). This framework (Table 1-2) considers the biological impairment in *body structure or function* (including psychological function) experienced by the individual and how that impairment interferes with the individual's *activity and participation* in daily events. Finally, consideration of *contextual factors* is advocated. These include social attitudes and beliefs about impairment, but also practical obstacles to well-being. Contextual factors are not considered in diagnosis—in other words, a child from a culturally diverse background should not be diagnosed with a language disorder simply because he or she cannot access the school curriculum due to language differences. However, for children with language disorders, identification of key activities and participation and the contextual factors that facilitate or hinder this participation can assist intervention planning.

ETIOLOGY OF DLD

Why Do Children Have DLDs?

One conclusion that we can be pretty certain of is that there is no single cause of DLD. This must be the case, since some children with ID have additional DLD; that is, language skills that are much less than would be expected not only for their chronological age,

TABLE 1-2 International Classification of Functioning (WHO, 2001): Implications for Diagnosis and Treatment

Construct	Includes	Diagnosis	Treatment Planning
Body function	Speech, language, communication, and literacy	Q: What is the child's level of communication functioning? Method: Standardized assessment of speech, language, communication, and literacy	Identify aspects of speech, language, communication, and literacy that are below chronological age expectations.
Body structures	Structure of the nervous system The eye, ear and related structures Structures involved in speech	Q: Are there any physical impediments to acquiring speech, language, communication, or literacy? Method: Hearing evaluation, oral-motor evaluation, and neurological assessment (if indicated)	Identify any aids, devices or medical interventions that might restore normative function; i.e., hearing aids, pharmaceuticals, oral-motor surgeries, etc.
Activities and participation	Learning and applying knowledge General tasks and demands Communication Self care Domestic life Interpersonal interactions and relationships Major life areas Community and social life	Q: Are there daily activities that are more challenging as a result of speech, language, communication, or literacy impairments? Method: Direct observation of child in different contexts (i.e., home or school), parent/teacher questionnaires, and discussion with child	Prioritize communication intervention in key areas of daily living (e.g., taking public transport, using the computer to contact friends, ordering food in a cafe). Develop strategies to alert others to communication needs.
Contextual factors	Products and technology Natural Environment and human-made changes to environment Support and relationships Attitudes Services, systems, and policies	Q: Is there anything that can be changed about the child's environment to facilitate communication and language/literacy learning? Method: Observation in different contexts, interview/questionnaires with significant others, review policies/practices of school, care, or employment services	Collaborative interventions that seek to modify communication behaviors of significant others, rather than child directly; encourage use of signs and /or symbols in school/work place; allocation of advocate or support worker; provision of computer or alternative communication device; extra time to complete exams/coursework

but even for their developmental level; while other children with ID, even with exactly the same nonverbal IQ, have much better language ability. We don't know why one child with ID has additional DLD and another does not, any more than we know why one child with an IQ in the normal range has primary DLD, while his next-door neighbor with the same nonverbal performance doesn't, or why one child with a 35 dB hearing loss has almost normal language, while another child with the same hearing level has significant language deficits. But we know that it happens. That's why in this book, although we discuss the etiologies associated with language disorders, we don't rely on the etiological label to tell us everything we need to know about a child's language. But we'll talk more about that later. For now, we'll just admit our basic ignorance about the causes of both primary and secondary DLD, and say that it's likely that multiple risk factors for disorder will co-occur to give rise to a diagnosable condition. These risks may arise from a biological disposition, from the child's pre- or post-natal experiences, or from chance events. In thinking about causal routes to DLD, it can be helpful to structure our thoughts according to "levels of explanation" (Morton, 2004; Morton & Frith, 1995). **Figure 1-2** illustrates this approach. At the bottom of the figure is the "behavioral" level; these are the observed characteristics of DLD that we are trying to explain. At the top is the "biological" level; these are the genetic influences and the differences in neurological structure and function that increase risk for impaired language development. We've alluded to the fact that there is no direct route from brain to behavior. For this reason an intermediate "cognitive" level is postulated that mediates biological and behavioral levels. At the cognitive level, we are interested in differences in perception, processing, storage, and learning of information that may contribute to language difficulties. Finally, the "environment" runs alongside each level, because environmental factors can influence each level of explanation. It makes sense that the child's environmental circumstances can have a profound effect on language development and behavior; for instance, numerous studies have demonstrated a link between level of maternal education and children's later language status (Reilly et al., 2010). However, the environment can also have substantial influences on biological mechanisms. For example, Meaney (2010) has discussed how

differences in early parental care can affect gene expression in offspring. Similarly, there is some evidence that environmental factors can induce differences in brain structure and function. Intervention is a key example; Krafnick, Flowers, Napoliello, and Eden (2010) reported changes in gray matter volume following an intensive reading intervention for dyslexic children. Environment can also influence cognitive processes. For example, differences in the age at which children succeed on tasks that tap understanding of other minds (known as "social cognition") appears to differ significantly depending on cultural and language differences (Lecce & Hughes, 2010; Liu, Wellman, Tardif, & Sabbagh, 2008). For these reasons, our discussions of etiological and cognitive factors associated with DLD includes each of these levels of explanation (**Figure 1-3**).

Many years ago, clinicians and researchers fiercely debated the origins of DLD: did language impairments reflect differences in *nature*, the biological capacity to learn and use language, or differences in *nuture*, the frequency and quality of language input to the child? Today, we have an understanding that the two forces interact within a developing child. We also have more information about the precise neurobiological and environmental factors that increase risk for DLD. However, we still have much to learn about the precise route from genes to brains to language behavior and how environmental factors can alter the developmental trajectories of each of these levels. In the sections below, we outline our current state of knowledge about the biological foundations and environmental influences on DLD.

Genetic Factors in DLD

Clinicians and researchers have known for some time that primary DLD tends to run in families, suggesting that genes may influence susceptibility to disorder. We cannot be sure of this, however, because families share environments as well as genes. Over the last 25 to 30 years, *behavioral genetic* methods, including family and twin studies, have been instrumental in specifying genetic and environmental contributions to disorder. These methods have also helped to refine the heritable DLD phenotype (the observable, measurable characteristics related to individual variations in genetic makeup); this in turn has facilitated exciting advances in molecular genetics, which are beginning to isolate the specific

FIGURE 1-2 Levels of explanation for developmental language disorder.

FIGURE 1-3 Example of explanations for developmental language disorder at each level.

genes implicated in DLD (see Bishop, 2009; Newbury, Fisher, & Monaco, 2010 for reviews).

Twin studies have been invaluable in establishing that DLD is a highly heritable disorder. Twin studies capitalize on the fact that monozygotic (MZ), or identical, twins are genetically identical, whereas dizygotic (DZ), or fraternal, twins share only 50% of segregating alleles (normal genetic variations). MZ twins resemble each other with respect to DLD diagnosis more closely than do DZ twins, with heritability estimates (i.e., the proportion of variance explained by genetic relationships) of 0.50 to 0.75 (see Bishop, 2009 for review). One notable exception to this highly consistent pattern was a population study of 4-year-old twins, which found negligible genetic influence on language impairment (Hayiou-Thomas, Oliver, & Plomin, 2005). In this study, children were classified as having DLD on the basis of standardized tests of speech and language (cf. Tomblin et al., 1997). Reclassification of this population found that heritability estimates increased substantially when referral to speech-language pathology services was used to index affected cases (Bishop & Hayiou-Thomas, 2008). This suggests that children attracting clinical attention may represent a phenotypically and etiologically distinct group.

This highlights the challenges that stem from investigating a complex and heterogeneous disorder like DLD; heritability estimates vary depending on the precise definition of DLD used, and isolating specific genes becomes much more challenging in the midst of phenotypic “noise.” Bishop (2006a) has advocated an approach that does not attempt to identify genetic influences on a diagnostic category such as primary DLD, but rather investigates genetic influences on underlying cognitive traits that affect language skills (known as *endophenotypes*). By identifying children at risk according to performance on marker tasks such as non-word repetition and morphosyntactic marking, rather than clinical diagnosis, Bishop and colleagues have demonstrated that both deficits are highly heritable, but weakly correlated, suggesting independent genetic influences (Bishop, Adams, & Norbury, 2006). On the other hand, deficits in auditory processing were not heritable and appear to be more influenced by environmental factors (Bishop et al., 1999). These studies have also demonstrated that the clinically identified and most severely affected children are ones who have multiple deficits. Thus, language may be fairly robust in the face of adversity, but accumulation of risk factors of either genetic or environmental origin may have deleterious consequences for language development.

The same “trait” approach has been applied to molecular genetic studies of primary DLD. Individuals are selected on the basis of poor performance on a standard measure of some aspect of language ability; for instance, families have been selected in which one member scored -1.5 SDs below the normative mean on one of three measures: non-word repetition, expressive language ability, or receptive language ability (SLI Consortium, 2002, 2004). Genome-wide screens have consistently found linkage (a correlation between an inherited stretch of DNA and a phenotypic trait) between chromosome 16q and non-word repetition and chromosome 19q and expressive language scores (see Newbury, Fisher, & Monaco, 2010 for review). These techniques enable investigators to narrow their search for specific genes implicated in these behavioral traits. There are currently five candidate genes that have been reliably associated with spoken language disorders: *FOXP2* and *CNTNAP2* on chromosome 7 (Vernes et al., 2008), *ATP2C2* and *CMIP* on chromosome 16 (Newbury et al., 2009), and *KIAA0319* on chromosome 6 (Newbury et al., 2011; Rice et al., 2009). Variations of some these genes have been associated with the ability to repeat nonsense

words; Newbury et al. (2009) found that individuals carrying risk variants of both *ATP2C2* and *CMIP* had average non-word repetition scores of 1 SD below the mean of individuals who did not carry risk variants of either gene.

However, finding an association between genetic variation and behavioral performance is only a first step in unravelling the relationships between genes and behaviors. In complex disorders, this relationship is probabilistic; even if we are able to definitively identify specific genetic variations associated with DLD, we still could not accurately predict individual phenotypes. In addition, genes do not encode specific behaviors—there is no “gene for non-word repetition.” Instead, it is most likely that normal genetic variations affect the efficiency of gene expression in the developing brain (Newbury, Fisher, & Monaco, 2010). With this in mind, it is important to note that the genes that have been implicated in DLD have also been implicated in a host of other neurodevelopmental disorders, including Tourette syndrome (Verkerk et al., 2003), attention-deficit hyperactivity disorder (ADHD; Ella et al., 2009), dyslexia (Newbury et al., 2010), autism spectrum disorders (Alarcon et al., 2008; Arking et al., 2008), epilepsy (Strauss et al., 2006), schizophrenia (Wang, Liu, & Aragam, 2010), and intellectual disability (Zweler et al., 2009). That these disparate disorders show at least partially overlapping etiologies may help to explain the high rates of co-morbidity seen in developmental disorders. How subtle variations in genes impact neural development in a way that adversely affects the course of language development, and why language should be particularly vulnerable across disorder groups are empirical questions that will occupy researchers in this field for a long time to come.

Neurobiological Factors in DLD

Language in the Brain

Before we consider how the brain might be different in DLD, we need to say a bit about key developmental processes that occur in the typically developing brain. It might surprise you to learn that the human brain starts developing in utero and continues to grow and develop throughout adolescence. The current view (see Johnson, 2005 for in-depth discussion) is that, initially, regional differences in the brain favor different types of input for processing or computations. Smaller regions within these areas become more specialized through activity-dependent processes that respond to environmental input. How the environment shapes neural development is to some extent constrained by the architecture of different brain regions, itself determined by genetic influences.

Increased cortical specialization and learning require changes in the number and strength of connections between neurons in order for more effective “communication” within the brain. In development, less is definitely more; a process of “synaptic pruning” eliminates weak or underused connections and helps to strengthen remaining connections. Ultimately, this results in specialized neural networks that are more finely tuned to processing particular inputs, known as “functional specialization.” This specialization also results in greater “localization” of information processing.

Language in the adult brain is a great example of localization and functional specialization. In most individuals, language processing is “left lateralized,” meaning it is processed predominantly by structures in the left hemisphere. As a result, the cortical structures that process language tend to be larger in the left hemisphere than homologous structures in the right hemisphere. Critical cortical areas for language are situated in the frontal and temporal lobes (Figure 1-4). Within the frontal lobe, the inferior frontal gyrus

FIGURE 1-4 Language-related areas in the left hemisphere of the brain. (From Tropper, B. & Schwartz, R. [2009]. *Neurobiology of child language disorders*. In R. Schwartz [Ed.], *Handbook of Child Language Disorder* (pp. 177; Fig. 7-1). N.Y.: Psychology Press/Taylor & Francis.)

includes the pars opercularis and the pars triangularis, which together form Broca's area. We know from studies of adults with lesions in this area that these structures are critically important for speech motor planning needed to produce spoken language. The temporal lobe contains structures important for auditory processing and language comprehension, historically referred to as Wernicke's area. Key structures in this region include Heschl's gyrus, the superior temporal gyrus, and the planum temporale. A fiber bundle, called the arcuate fasciculus, connects the frontal and temporal regions, thus linking the brain regions involved in the production and comprehension of oral language.

These areas are prime candidates for investigating the neurobiological basis of DLD. Researchers do this using neuroimaging techniques described in Box 1-2. These methods have demonstrated that, unlike cases of adult stroke, there are no gross lesions of these neurological structures that could cause DLD; indeed when such lesions do occur in childhood they rarely result in such profound language impairments (see Chapter 4). However, researchers have identified subtle differences in brain structure and function that are *associated* with primary DLD, BUT: anomalies in brain development are not deterministic—some individuals have brain differences and yet develop language as expected (see C. Leonard et al., 2006). However, the presence of these anomalies substantially increases *risk* for disorder. So what are the neurobiological risk factors for DLD?

Brain Structure in DLD

Only a handful of investigators have applied structural magnetic resonance imaging (MRI) to the study of primary DLD. The most consistently reported finding is that, as a group, individuals with primary DLD show atypical patterns of asymmetry of language cortex (De Fosse et al., 2004; Gauger, Lombardino, & Leonard, 1997; Herbert et al., 2005; Jancke, Siegenthaler, Preis, & Steinmetz, 2007; Plante, Swisher, Vance, & Rapsak, 1989, 1991). Other relevant findings have included abnormalities in white matter volume (Herbert et al., 2004; Jancke et al., 2007), cortical dysplasia (abnormalities in the organisation of different types of brain cell; Galaburda, Sherman, Rosen, Aboitiz, & Geschwind,

1985), additional gyri in frontal or temporal regions (Clark, 1998; Jackson & Plante, 1997), and unusual proportions of anatomical structures implicated in language processing (Jernigan, Hesselink, Sowell, & Tallal, 1991; Leonard et al., 2002; Leonard, Eckert, Given, Berninger, & Eden, 2006).

Despite these differences, the relationship between structure and function is far from perfect. For instance, Plante et al. (1991) investigated patterns of asymmetry not only in boys with DLD, but in their siblings and parents as well. The majority of these relatives also had deviant patterns of asymmetry, but not all of them had DLD. Christiana Leonard and her colleagues have further highlighted the probabilistic nature of developmental anomalies in brain structure. Leonard et al. (2002) contrasted children with DLD and children with dyslexia and sought to identify the structural brain features that distinguished the two groups. Children with DLD tended to have a smaller surface area of Heschl's gyrus in the left hemisphere and the planum temporale tended to be more symmetrical, relative to children with dyslexia. Leonard et al. (2006) replicated and refined this anatomical risk index: children with a negative risk index had smaller and more symmetrical brain structures and experienced more marked and pervasive deficits in language comprehension. In contrast, children with a positive risk index had larger brain structures and exaggerated asymmetry; these children had significant phonological deficits and reading impairments, but relatively preserved language comprehension. Further research by this group has revealed that the anatomical risk index is applicable in other disorders, such as schizophrenia, that may involve aberrant language development (Leonard et al., 2008).

Brain Function in DLD

Two techniques have been used to study the way children with primary DLD function differently from typical controls: functional magnetic resonance imaging (fMRI) and electrophysiological measures.

fMRI

Studies of brain function in primary DLD using MRI are rarer than studies of brain structure and are limited by small sample sizes and task difficulties. Hugdahl et al. (2004) investigated language

BOX 1-2 How Do We Study Language in the Human Brain?

Recent advances in neuroimaging technology provide non-invasive methods of investigating the structure, function, and connectivity of brain regions implicated in language processing.

Magnetic resonance imaging (MRI) uses strong magnetic fields and nonionizing radio frequency energy to generate a signal from the body. In structural MRI, this signal enables detailed measurement of the volume, shape, and position of brain tissues. One advantage of MRI is that different components of brain structure, such as subcortical structures (brain structures lying beneath the cerebral cortex), white matter (consisting mostly of myelinated axons, or the brain's "wiring"), and gray matter (a layer of neuronal cell bodies) have different intensities (or contrasts) allowing detailed anatomical structures of the brain to be visualized. The typical spatial resolution of such structural images is approximately 0.5 to 1 mm³, which represents anatomical groups of several hundred thousand neurons.

Functional MRI (fMRI) refers to the use of MRI scanners to detect brain activity in response to some external stimuli. The most widely used type of functional MRI is known as blood oxygenation level dependent (BOLD) imaging, which takes advantage of the fact that oxygenated and de-oxygenated blood have different magnetic properties. As neurons become active, they consume oxygen leading to compensatory changes in blood flow to the active area that can be detected in an MRI scanner. The BOLD signal is therefore an indirect measure of neural activity. fMRI is usually regarded as having sufficient spatial resolution to allow inferences about the location of neural activity to be made. However, because blood flow changes relatively slowly (5 to 8 seconds after the external event), temporal resolution is poor and limits the use of fMRI for the study of the time course of language processing.

Diffusion tensor imaging (DTI) is a technique that allows us to examine the anatomical connectivity between different brain regions. It exploits the fact that water molecules diffuse differently around white and gray matter; water moves slowly and in many different directions through gray matter, but quickly and less diffusely through white-matter tracts. DTI tracks the movement of water molecules over time, enabling identification of the location and orientation of white-matter tracts.

Functional transcranial doppler ultrasound (fTCD) is a non-invasive and less costly method for assessing cerebral lateralization. The procedure involves measuring blood flow in the middle cerebral artery via an ultrasound probe placed just in front of the ear. In typical development, it is possible to see a clear increase in left-sided blood flow during language generation, with lateralization agreeing well with that obtained using other methods. It is particularly well-suited for studying

language lateralisation in young children, because it is not loud or intimidating and does not require the participant to remain still to the extent that MRI does. A video of this procedure applied to the study of language can be viewed here: www.jove.com/Details.stp?ID=2161.

Near infrared spectroscopy (NIRS) is used in medical contexts as a non-invasive measurement of the amount and oxygen content of hemoglobin. It can be used for non-invasive assessment of brain function through the intact skull in human subjects by detecting the absorption of light, which is sensitive to the concentration of hemoglobin, to measure activation changes in blood hemoglobin concentrations associated with neural activity. NIRS measures changes in blood oxy- and deoxy-hemoglobin concentrations in the brain as well as total blood volume changes in various regions of the cerebral cortex using near-infrared light. The NIRS system can determine the activity in specific regions of the brain by continuously monitoring blood hemoglobin level. In this way, it can be a partial replacement for fMRI, and does not require patients to lie still in a closed, noisy chamber. NIRS can be used on infants, where fMRI is difficult, and NIRS is much more portable than fMRI machines; even wireless instrumentation is available, so that subjects can move about during the procedure. However, at this time, NIRS cannot fully replace fMRI because it can only be used to scan cortical tissue, whereas fMRI can be used to measure activation throughout the brain.

Electrophysiological measures such as electroencephalogram (EEG) and magnetoencephalography measure the tiny electrical currents or associated magnetic fields, respectively, that are associated with the firing of many hundreds of thousands of neurons in the human brain. These techniques measure this electrical activity through hundreds of electrodes/sensors placed on the scalp and provides a more direct measure of brain function. A major advantage of EEG or MEG is that measurement of electrical activity may be time-locked to an external stimulus, such as a spoken word or sentence, allowing a moment by moment picture of neuronal response to language (an "event-related potential," or ERP). This superior temporal resolution allows us to make inferences about the time-course and speed of language processing, but comes at the cost of poorer spatial resolution. Indeed, it is now quite common for language researchers to combine MRI methods (good spatial resolution) with EEG/MEG (good temporal resolution) to better understand language processing.

All of the above methods are noninvasive and do not require any form of ionising radiation or the administration of contrast agents (e.g., gadolinium). This is of particular advantage in studies of DLD as participants can be assessed and scanned repeatedly over time, allowing researchers to visualize how the language areas develop with age.

processing in five Finnish family members with DLD and six age-matched peers as they listened passively to isolated vowel sounds, pseudowords, and real words. The family members with DLD showed bilateral activation in the temporal lobes, including the medial temporal gyrus and the superior temporal sulcus, which was much weaker and more focal than activations seen in the comparison group. This reduced activation is believed to be associated with the difficulties individuals with DLD have in decoding the phonological structure of words and pseudowords (Friederichi, 2006).

Weismer, Plante, Jones, and Tomblin (2005) investigated working memory abilities using fMRI in eight teenagers with primary DLD and eight individuals with normal language (NL) abilities. Like Hugdahl et al. (2004), they found that individuals with DLD exhibited hypoactivation in frontal and parietal regions that are implicated in memory and attention and the inferior frontal gyrus, commonly associated with semantic processing and other aspects of language processing. However, the participants performed more poorly on the working memory task overall, so it is not

clear whether these differences are attributable to working memory deficits specifically, or increased/decreased effort in task performance.

Obtaining brain scans from young children and children with developmental concerns using MRI is not always easy; the scanner is large and noisy and participants have to keep very still while lying in a restrictive space. Dorothy Bishop and colleagues have been developing a technique called functional transcranial Doppler ultrasound (fTCD), which is a more user-friendly method of investigating cerebral lateralization (see [Box 1-2](#)). She has demonstrated that adults with DLD show reduced blood flow to the left hemisphere when engaged in language tasks, providing evidence of reduced lateralization of language (Whitehouse & Bishop, 2008). Near-infrared spectroscopy is another new technique being employed in language studies (Bortfeld, Wruck, & Boas, 2007; Kuhl, 2010).

Despite the contradictory findings and confusions in the literature, a number of observations can be made. First and foremost, the direction of causation in reported brain differences is not at all clear. Do differences in brain structure or activation cause language impairment, or do these differences arise as a result of a lifetime of processing language differently? Second, the relationships between brain and language in DLD are weak and probabilistic, and not specific to DLD (Herbert et al., 2005; Leonard et al., 2006). Comparisons across developmental disorders will be necessary to identify clearer relationships between disorder and brain anomaly (cf. DeFosse et al. 2004; Leonard et al., 2006). Finally, the anomalies that are associated with DLD appear to arise early in development, rather than as a result of an early acquired lesion. Bishop and Norbury (2008) suggest that this is consistent with genetic influences on brain development leading to a brain that is wired up in a non-optimal fashion for language learning.

Electrophysiological Measures

Relative to studies of primary DLD using MRI, many more studies have explored language processing using electroencephalograms (EEG). This technique allows investigators to measure the electrical brain activity that is directly related to a specific external event (hence the term “event-related potential” or ERP; see [Box 1-2](#)). ERPs are displayed as wave forms and are described in terms of components that vary with respect to polarity (positive or negative), the latency of peak occurrence (time elapsed between when the stimulus is delivered and when the peak occurs), and their topographical distribution (location) over the scalp. The patterns of ERP response change dramatically over time, making it an ideal method for exploring continuities and discontinuities in DLD (see Friederici, 2006 for a review). For example, the N400 (a negative peak that is seen 400 msec. after a stimulus is delivered) is an ERP component that is thought to index semantic processes; it is observed in the centroparietal region of the brain. When typical individuals are confronted with semantically anomalous or incongruous material, these elicit a larger N400 response relative to semantically congruous material, reflecting increased processing effort. Individuals with DLD and their fathers tend to show exaggerated N400 responses in both situations (Ors et al., 2001).

Another advantage of ERPs is that they allow us to investigate auditory processing without requiring children to attend to the stimuli or engage in an overt task. In this case, an oddball paradigm in which children hear a “standard” stimulus (usually a tone or speech sound, for example, /ba/) that repeats regularly is punctuated occasionally by the “deviant” stimulus (a change in tone or speech sound, /da/). Each sound is compared to the memory trace of the last sound, thus, if the new sound is different, it should elicit

a larger response as the brain registers novel input. The difference in waveforms between the standard and the deviant is referred as the “mismatch negativity” (MMN): a sharp negative shift between 100 and 300 msec. post stimulus onset that is thought to index automatic encoding of acoustic change and potentially memory traces of auditory information (see Bishop, 2007). Studies employing this technique in children with DLD have tended to show a reduced MMN response (Bishop, Hardiman, & Barry, 2010); longitudinal studies indicate that the brain responses of children with DLD are immature, showing a similar pattern of response to younger, typically developing children (Bishop & MacArthur, 2005).

So, there is clear evidence that biological factors are associated with DLD, but we have to be careful about assuming the causal directions of these effects. Prospective studies of infants selected because of genetic risk for DLD are lacking; such studies would allow us to trace brain structure and function developmentally, enabling us to determine if brain differences occur prior to language onset, or result from years of faulty language processing. We also need to stress the probabilistic nature of these biological risk factors; not all children with risk gene variants or negative anatomical indices go on to have DLD. One key implication of this is that brain scans to diagnose DLD are highly unlikely! It also means that in our assessments of children and families we need to consider risk from multiple levels of explanation, in order to weigh up the child’s prognosis.

And as little as we know about genes and brains in children with primary DLD, we know even less about DLD that is secondary to other disorders. Very little research has been done on the language features of DLD that is secondary to ID, ASD, hearing impairment, or the other disorders DLD can accompany, and we have no explanation for why Sam and Max, two 12-year-olds who each have an IQ of 50, are as different as [Box 1-3](#) describes. But

BOX 1-3 Sam and Max

Sam is a little charmer. When he meets you, he walks right up to you, shakes your hand, and says, “Hi, I’m Sam. What’s your name?” In school, he gets reading and writing instruction and does well on the primary-level readers that have been adapted for his use. Sam is in a special vocational training program in which he works in his middle school’s cafeteria each lunch period, helping to refill the steam trays. All of the cafeteria workers are fond of him and look forward to hearing him tell them what he did in class each morning when he comes in for work at noontime. Sam follows the cafeteria staff’s directions easily and cheerfully and doesn’t get confused when he is told to do a new task, as long as it is explained slowly with some demonstration.

Max works with Sam in the cafeteria at lunchtime and does a good job at the tasks that he’s practiced for some time. He seems quiet, though, and rarely talks spontaneously. Even when spoken to, he answers in one or two words, which are often so misarticulated that the cafeteria workers don’t understand what he says. Max’s teachers and parents have worked hard to try to improve his social communication and to increase his spontaneous speech, but it’s an uphill battle. He just doesn’t seem to have much to say to anyone, and even when he does, he can’t seem to put more than two or three words together to say it.

the fact that we know children like Sam and Max exist means that knowing a child's diagnosis or developmental level—or his genetic make-up or neurobiological status, for that matter—won't be enough to decide how to address his communication difficulties; we'll need to know about those communication difficulties themselves, regardless of their underlying cause(s). It is the detailed description of communicative competence that will define a communication intervention program. We'll return to this point later.

One final point should be made before leaving this section. Few clinicians share our enthusiasm for etiological studies that highlight genetic and neurological origins of DLD, reasoning that if the problem is in the brain or the genes, there is little we can do about it. We hope what we've discussed so far has convinced you that this is not the case at all. As illustrated in Figure 1-3, the environment exerts strong influences on gene expression and neurological development, as well as on behavior. Intervention is therefore a powerful environmental tool that can shape development and positively influence behavioral outcome. This has been demonstrated in other areas of medical research; dietary restrictions to combat the effects of phenylketonuria, now identified through newborn screening, is an excellent example. What other environmental influences have been linked to language learning and disorder? Let's take a look.

Environmental Factors

Conventional wisdom tells us that if only parents would turn off the television and spend some time talking to their children, we could ameliorate DLD. However, the research evidence is that language learning is remarkably robust in the face of impoverished language input; so it appears that environmental factors alone cannot account for the relatively circumscribed deficits in grammar that characterize DLD (Bishop, 2006b). Nevertheless, environmental factors can have an important role in mediating the developmental course of the disorder and the impact of disorder on the child's adaptation and well-being.

Family socioeconomic status (SES) has long been associated with language development; children from families with low SES have protracted rates of language development relative to peers from more affluent environments. Hoff and Tian (2005) suggested that the relationship between SES and language impairment is mediated by maternal education, via the quantity and quality of mothers' interactions with their children. However, other studies have found that SES (measured by income or maternal education) is not a reliable predictor of long-term language impairment (Dale, Price, Bishop, & Plomin, 2003; Zubrick, Taylor, Rice, & Slegers, 2007). Furthermore, environments are often at least partially genetically influenced, in other words, limited education and lower incomes may reflect parental language impairments. Therefore, DLD in the context of low SES should alert clinicians and educators to the need for careful monitoring and language support.

In a multi-cultural society, clinicians are frequently asked whether or not exposure to more than one language can cause language delay or exacerbate language impairments. Unfortunately there is very limited evidence available to address these important questions. In general, the view is that exposure to two or more languages does not cause or compound DLD (Paradis, Crago, Genesee, & Rice, 2003) and families are advised to provide rich linguistic input to their children in whichever language they themselves are most comfortable speaking. We will discuss this issue in more detail in Chapter 5.

Culturally appropriate assessments can include informal observation of play behavior.

Cognitive Models of DLD

In primary DLD, cognitive theories have attempted to explain why language may be disproportionately impaired relative to other developmental achievements. In the past, theories have suggested that the grammatical deficits that characterize DLD occurred because of a "selective" deficit in dedicated cortical structures that subserve language (cf. van der Lely, 2005). However, our recognition that grammatical deficits are rarely "all or nothing," coupled with our understanding of the developing brain means that a strong version of this hypothesis is no longer tenable. Increasingly, researchers and theorists are trying to elucidate the more general cognitive processes that, if faulty (or inefficient), could render language acquisition unduly challenging. Like many other aspects of DLD, there is little consensus about which theory is right. It is very likely that more than one deficit is necessary to derail language learning to the extent seen in DLD. The pros and cons of key theories are highlighted below.

Auditory Processing

Auditory accounts of DLD have argued that children with DLD have difficulties perceiving sounds that are presented rapidly, are of brief duration, and therefore are not perceptually salient. Such deficits could conceivably lead to problems perceiving and categorizing meaningful phonemic contrasts, leading to problems with language learning (Chiat, 2001). Furthermore, many grammatical contrasts in English are signalled with unstressed phonemes of brief duration occurring in a rapidly changing speech stream; thus, a general impairment in temporal or perceptual processing may lead to highly selective impairments in grammatical processing (Joanisse & Seidenberg, 2003). Although an intuitively attractive account of DLD, auditory deficits have been shown to be neither necessary nor sufficient to cause DLD. Notably, while auditory deficits are more common in children with DLD, not all children are affected and some children with auditory deficits do not have any language difficulties (McArthur et al., 2008). In addition, intervention studies have indicated that improving auditory skills does not confer improvements to other aspects of language or literacy, calling the causal relationship into question (see Strong, Torgeson, Torgeson, & Hulme, 2011 for a meta-analysis of one such intervention program).

FIGURE 1-5 Model of bottom-up language processing presented by the Illinois Test of Psycholinguistic Abilities. (Used with permission from Kirk, S, McCarthy, J, and Kirk, W (1968). *Illinois test of psycholinguistic abilities* (revised edition). Urbana, IL: University of Illinois Press.)

Limited Processing Capacity

Leonard (1998) argued that perceptual deficits are more detrimental to language development in the context of a system that has limited capacity to hold information in store while processing perceptually challenging input. Evidence for a limited capacity system stems from poor performance on tasks of working memory and phonological short term memory (see Vance, 2008 for review). Measures of working memory typically require children to make true/false judgements about simple statements such as “balls are round” and “pumpkins are purple” (the processing component) and then recall the last words of each statement, “round” and “purple” (the capacity component). The argument is that there is a trade-off between processing and capacity, so that when processing demands increase, capacity for recall is reduced and vice versa. If this is true, children with DLD would be expected to have greater difficulty processing sentences of increasing length and complexity. Indeed, Montgomery and Evans (2009) demonstrated such a relationship in young people with DLD.

Remember the non-word repetition task? Deficits on this task are thought to index phonological short-term memory, as children with DLD tend to have more difficulty at increasing syllable length (“hampent” vs. “blonterstaping”). The significance of the test relates to its role in language learning; acquiring new words depends on the ability to retain novel sound sequences in memory, learning syntax requires the child to hold sentences in memory while they are analysed. Thus, it has been argued that a deficit in non-word repetition (NWR) could lead to a host of language deficits (cf. Graf-Estes et al., 2007).

But what does the NWR test actually measure? Bloom and Lahey (1978) were among the first to point out that auditory processing and other cognitive models of DLD generally take a “bottom-up” view of language processing. In a “bottom-up” model, lower-level processes, such as perception and discrimination,

provide input necessary to the function of higher-level processes such as comprehension. Figure 1-5 illustrates such a model. But, as Bishop (1997) and Lahey (1988) made clear, these “lower-level” processes do not operate in a vacuum or on a blank slate. Instead, they work in the context of prior knowledge. So prior knowledge, including knowledge of language, always influences how one processes input. For example, suppose that an examiner gave you these two lists of words to memorize and repeat:

LIST 1	LIST 2
Gigan	Pterodactyl
Gigantis	Giraffe
Angiris	Hippopotamus
Mogra	Triceratops
Megalon	Tyrannosaur
Hedora	Alligator
Mothra	Rhinosauos
Minya	Elephant

From which list do you think you could recall more items? Most people choose List 2. Even though the words in it are long, they are generally more familiar (the names of large animals, living and extinct). List 1, though, would be easier to learn if you had the appropriate background knowledge. You see, List 1 contains the names of characters from several *Godzilla* movies. For *Godzilla* aficionados, this list, too, contains familiar elements and would be readily recalled. In fact, when we began to write out this list for you as an example, we could only recall three or four of the

Godzilla characters' names. We had to put in a quick call to a 6-year-old Godzilla fan we knew, and asked him to name all the monsters in the Godzilla movies he'd seen. He rattled them off without hesitation, producing more than we needed for the list!

Now, let's say you were given List 1 to repeat after one brief presentation without prior knowledge or associations with the words on it. Suppose you scored significantly lower than some other subjects, say, people who were attendees at the Godzilla Fan Club International Convention. Would it follow that you had auditory memory deficit? Of course not! Your familiarity with the stimuli strongly influences how easy they are to remember and recall.

The same might be said of a 5-year-old with a DLD who is trying to complete the NWR test. Success on this task is related to the "wordlikeness" of the non-words or the extent to which they have real words embedded in them (Dollaghan, Biber, & Campbell, 1995; Gathercole, 1995). In other words, the more a non-word resembles a known word in a person's vocabulary (e.g., trumpet—trumpetina), the easier it is to remember. Children with DLD who have smaller vocabularies will have fewer words on which to "hook" novel words. So again, this deficit may be seen as more a consequence than a cause of DLD. Just as you had trouble remembering "Angiris" because you hadn't heard or used the word before and had no associations with it, our child with DLD has the same problem with "trumpetina" because he has very limited experience with the word "trumpet." Ask him to recall several of these relatively unfamiliar terms, and he'll show the same difficulty you had in recalling "Angiris," "Mothra," "Gigan," and "Minya."

Now, there is little doubt that children with DLD have substantial verbal memory deficits, but the direction of causation is debatable. Cognitive theories that take a bottom-up view of language processing often fail to take into account evidence for top-down influences on task performance. In fact, the sensitivity of the NWR test in identifying DLD may stem from the complexity of the test and the fact that it taps a number of different underlying skills (Archibald & Gathercole, 2007; Coady & Evans, 2008). Similarly, verbal working memory tasks are essentially complex language tasks, making poor performance in DLD populations difficult to interpret (Baird et al., 2010). Recent findings of working memory deficits outside the verbal domain lend credence to the view that domain-general cognitive processes contribute to language difficulties (Bavin, Wilson, Maruff, & Sleeman, 2005).

Procedural Deficits

Ullman and Pierpont (2005) made a distinction between procedural memory systems, which are important for rule-based learning (such as grammar), and declarative memory systems, which underlie knowledge-based learning (such as vocabulary). They hypothesized that DLD was the result of a primary deficit in procedural memory systems, which could potentially be compensated for by reliance on relatively intact declarative systems. The appeal of this theory is that it makes explicit connections between brain and behavior, has the potential to explain deficits outside the language system that are also contingent on procedural learning (such as some motor tasks), and is developmentally more attractive in its emphasis on reorganization and compensation. Several recent investigations have noted that children with DLD are impaired on measures of implicit learning, which tap procedural memory systems (Evans, Saffran, & Robes-Torres, 2009; Lum et al., 2010; Misyak, Christiansen, & Tomblin, 2010), and that performance on

these learning measures is correlated with language scores (Evans et al., 2009; Misyak et al., 2010). However, impairments in learning are not limited to procedural memory systems (Lum et al., 2010) and extend to declarative memory impairments involved in learning facts and associations.

The conclusions from theoretical studies of DLD are that there is unlikely to be a single cognitive factor that can cause the variety of language profiles seen in DLD. What is perhaps even more important is that attempts to remediate underlying cognitive processes have generally not been any more successful in improving language performance than interventions that specifically target language behavior. This is the reason that in later chapters we will focus on assessing and remediating language behavior rather than potential underlying cognitive mechanisms.

Figure 1-3 summarizes the biological, cognitive, and environmental contributions to primary DLD that have been reported in the literature. It is unlikely that these are the only factors and it may be that the combination of factors the child brings to the task of language learning is more important than any one particular risk. An interesting question for researchers and clinicians alike is whether these same factors confer risk for language impairment in other developmental conditions such as autism spectrum disorder, and how the additional risks associated with these disorders impacts language development in other ways. It is certainly the case that rates of language impairment in autism spectrum disorders and literacy disorders are much higher than we would expect from chance; shared underlying etiology may help to explain why this is so.

COMORBIDITY IN DLD

Comorbidity refers to a situation in which a child may experience two or more disorders simultaneously. An important question concerns the nature of the relationship between these two disorders: Do they arise from completely independent causal origins, or are they causally related? Pennington and Bishop (2009) provide an excellent discussion of the comorbid relationships between speech sound disorders, reading disorders, and DLD. Here we consider two disorders in which comorbid language impairments occur at extremely high rates, increasing the likelihood that these children will form a substantial proportion of the average clinician's caseload.

Autism Spectrum Disorders

Early studies comparing children with ASD and DLD reported considerable overlap in structural language profiles (especially vocabulary and grammar) of the two disorders, though children with ASD invariably had more severe impairments (Bartak, Rutter, & Cox, 1975). However, these studies also highlighted language behaviors that reliably differentiated the two groups. Children with DLD were more likely than peers with ASD to have impairments in speech production; recent studies have also demonstrated that articulation deficits rarely feature in ASD (Kjelgaard & Tager-Flusberg, 2001). The language profiles of children with ASD, on the other hand, were more likely to be characterized by deviant features that would not be regarded as typical at any age; these features include repetitive use of stereotyped phrases, unusual and exaggerated intonation, pronoun reversal, idiosyncratic words, echoing the speech of others, and failure to respond to the speech of others.

Furthermore, pragmatic skills, or the use of language, is universally impaired in ASD (see Tager-Flusberg, Paul, & Lord, 2005 for a review), whereas children with DLD present with more variable pragmatic skills.

Textbook cases of ASD and DLD are relatively easy to distinguish; the prototypical child with DLD enjoys social interactions, seeks friendships with his or her peers, is keen to communicate, and uses gesture and other forms of nonverbal communication to get his or her message across. However, many children present with a symptom profile that does not unambiguously align with either diagnosis. These children have pragmatic deficits that cannot be fully accounted for by the grammatical impairments that are more characteristic of DLD, yet they do not have the full triad of impairments in severe enough form to warrant a diagnosis of autism. Differential diagnosis may be further hampered by a clinical picture that changes with time; children with unequivocal diagnoses of DLD early in development may more closely resemble individuals with ASD years later when structural language impairments resolve and the social demands of society increase (cf. Howlin, Mawhood, & Rutter, 2000; Michellotti et al., 2002). Conti-Ramsden, Simkin, and Botting (2006) applied standard diagnostic assessments (Autism Diagnostic Interview—Revised; LeCouteur, Lord, & Rutter, 2003; Autism Diagnostic Observation Schedule; Lord, Rutter, DiLavore, & Risi, 2001) to 76 adolescents with DLD, none of whom had been regarded as having DLD at the age of 7. Although the majority of adolescents did not meet criteria on either measure, 3.9% of participants met criteria on both, a prevalence rate approximately three times greater than would be expected from the general population (Baird et al., 2006). A further 26% met criteria on one or other measure but not both. Similar findings are reported by Bishop and Norbury (2002) and Bishop, Whitehouse, Watt, and Line (2008). Both studies found that children were more likely to meet criteria on these measures if they had been identified as having “pragmatic language impairment”; however, repetitive and restricted interests and behaviors were not characteristic of these children. It is still an open question as to whether this overlap represents misdiagnosis, a changing symptom profile in which children with DLD develop more autistic behaviours over time, or “diagnostic substitution” (Bishop et al., 2008), in which today’s more inclusive diagnostic criteria identify children who would not have met more stringent diagnostic criteria in the past. Bishop et al. (2008) argue that a proportion of children diagnosed with DLD have pragmatic impairments and some evidence of autistic symptomatology, but that these children are eager to communicate and their pragmatic deficits do not interfere with daily family life, contrary to the more traditional image of a child with ASD.

Recently there has been considerable research interest in the heterogeneous language profiles of children with ASD. Kjølgaard and Tager-Flusberg (2001) first noted that a sizeable proportion of children with ASD also met diagnostic criteria for DLD (see also Loucas et al., 2008). Subsequent studies delineated behavioral similarities in morphosyntactic and nonword repetition deficits (Tager-Flusberg, 2006), literacy difficulties (Lindgren et al., 2009), and overlaps in neurobiological anomalies (Tager-Flusberg & Joseph, 2003). Children with autism and DLD appear to have more significant impairments in language comprehension, suggestive of a ‘double deficit’ that results in a more severe profile (Loucas et al., 2008).

A strong hypothesis that emerges from these findings is that the same causal factors that confer risk for DLD also increase risk for

language impairment in ASD. Of course, not everyone agrees (Whitehouse et al., 2007; Williams, Botting & Boucher, 2008). There are subtle differences between the language characteristics of children with ASD and those with DLD, and the patterns of family performance also differ substantially between the two groups (Lindgren et al., 2009), raising doubts about the degree of shared etiological overlap. However, we might expect that children with ASD will have qualitative differences in language performance *because they have ASD*; the combination of DLD risk genes and ASD risk genes may also impact on family patterns of language performance (Bishop, 2010). So the jury is still out on the nature of the relationship between the two disorders. Nevertheless, there is no doubt that many children with ASD have language impairments that require careful assessment and intervention planning.

Language Learning Disabilities (Literacy Disorders)

Skilled reading requires the marriage of two complementary skills: reading accuracy (the ability to decode single words) and reading comprehension (understanding connected text) (Hoover & Gough, 1990). Extensive research on typical reading development has demonstrated that these skills are in turn reliant on underlying language processes (see Bishop & Snowling, 2004, for a review). Decoding in alphabetic languages such as English requires the mapping of orthography (the letters of printed words) to phonology (the sounds represented by the letters). Decoding alone does not guarantee literacy success, because the ultimate goal of reading is to extract meaning from printed text. Reading comprehension is supported largely by nonphonological language skills such as semantics and contextual processing (Perfetti, Landi, & Oakhill, 2005). Although decoding and comprehension frequently develop in concert, they may be dissociated (Bishop & Snowling, 2004).

Children who experience problems decoding printed text are frequently referred to as having ‘dyslexia’. The majority of children with dyslexia have phonological processing difficulties that disrupt their decoding abilities, leading to the prevailing theoretical view that phonological impairments are the primary cause of dyslexia (see Snowling, 2000, for review). Deficits in other aspects of language have also been reported in dyslexia. For instance, McArthur, Hogben, Edwards, Heath, & Mengler (2000) found that approximately 50% of children identified as having a specific reading disability also met criteria for DLD (defined as Total Language scores of 85 or less on the CELF) and a similar percentage of children identified as having DLD achieved significantly low scores on a measure of reading accuracy.

Children who experience problems understanding text despite adequate decoding skills are commonly referred to as “poor comprehenders.” Nation, Clarke, Marshall, and Durand (2004) investigated the language profiles of poor comprehenders and found that although the group scored within normal limits on measures of phonological processing, as a group they showed significant deficits in all other language domains, including vocabulary, grammar, verbal working memory, and higher-level discourse processing (i.e., making inferences) relative to skilled comprehenders. In addition, approximately 30% of poor comprehenders met criteria for DLD, depending on the cut-off scores used for diagnosis.

There is little doubt that DLD places children at greatly increased risk for reading impairments, contributing to lower educational attainments (Catts, Fey, Tomblin, & Zhang, 2002; Snowling, Adams, Bishop, & Stothard, 2001). The particular

profile of literacy skill will depend in part on the child's profile of language impairment; however, children with deficits in language comprehension have particularly poor literacy outcomes. For example, in a longitudinal study of children attending language units at age 7, Botting, Simkin, and Conti-Ramsden (2006) found that 67% of children with predominantly expressive language impairments and 88% of children with comprehension deficits had literacy impairments at age 11.

The considerable behavioral overlap between reading disorders and DLD have led many to regard the two as symptoms of the same underlying disorder, simply representing different points on a continuum of severity. However, this might be an overly simplistic conclusion, because severity of language impairment does not necessarily predict severity of reading deficit; there are children who read accurately despite DLD (Bishop, McDonald, Bird, & Hayiou-Thomas, 2010). In addition, evidence for consistent overlap between the two disorders at the biological or genetic level is lacking. Most importantly, the relationship between the two disorders cannot be fully captured by a single dimension of severity. Instead, Bishop and Snowling (2004) advocated the need for at least two dimensions of impairment to characterize the relationship between reading disorders and DLD: a phonological dimension and a nonphonological language dimension that incorporates semantics and grammar. Thus for children with DLD, the profile of reading difficulty should map onto the profile of language impairment experienced by the child.

CONCLUSION

In this chapter we have discussed some of the issues that face speech-language pathologists when engaging in clinical practice with children. We have talked about definitions and terminology, and we have explored some of the difficulties and controversies surrounding these issues. We have given you our view on these things, but have also noted that there is rarely consensus in the field. Many researchers and practitioners in the field would disagree with some of our comments, but until definitive research allows us to achieve consensus, each individual clinician must make an independent decision. We've tried to give you some of the information you need to make those decisions.

We've also given you some frameworks for assessing and treating DLD that will be examined in more detail in later chapters. In addition, we've discussed a range of causal models for primary DLD, and how these may be related to other developmental conditions in which language may be impaired. We'll discuss these situations in more detail in Chapter 4. Finally we've discussed three major tenets that lead to the model of assessment and intervention practice we will advocate in this book, which, for want of a better term, we call a descriptive-developmental approach. We'll make these tenets, and the descriptive-developmental approach that grows out of them, explicit now.

The first tenet concerns the role of etiology in developing assessment and intervention for children with DLD. We've shown you that even the most advanced science today does not go very far in explaining how DLDs, either primary or secondary, arise. And we've given you several examples to show you that the diagnostic category into which a child is placed may not always either explain or predict language behavior. Knowing the etiology of DLD does not, in itself, tell us what a child's communication is like and what is needed to enhance it. We would make the argument that, as

important as etiology is for understanding a child's condition, we need something in addition to develop an intervention program. That something is a detailed description of the child's current language function. It is this thorough delineation in terms of the use of vocabulary, meanings expressed, use of syntactic rules and morphological markers, pronunciation of sounds, knowledge of phonological rules, and the appropriate use of language for communication in social contexts—in other words, the range of language performance, including form, content, and use—that determines the course of intervention, and the course of assessment is determined by the aim of collecting this comprehensive description.

The second tenet of our approach suggests that it is much more important to detail the child's language skills themselves than to have extensive information on memory, auditory perceptual or perceptual-motor abilities, or skills typically tested in "auditory processing" test batteries. The reason is that, as we've discussed, we don't always know the direction of causation when children with language problems perform poorly on bottom-up processes like these. Since we don't know if these auditory, processing, and memory problems are chickens or eggs, we can't rely on remediating them to have any effect on language. Instead, we work directly on the language forms and functions that assessment identifies as disordered. So we don't address "auditory processing" or "verbal memory," we work on functional understanding and use of sounds, words, and sentences in real communicative contexts. Extensive reviews (cf. Guralnick, 1997; Law, Garrett, & Nye, 2005) of treatment research done over the past 20 years support the notion that treating language goals directly results in improved language behavior, especially for expressive language behavior. There are still many questions about the best methods for remediating language disorders, the best time to initiate and terminate services, the best candidates for intervention, and other issues. But it does seem clear that language behaviors can be changed for the better when targeted directly and that communication improves as a consequence.

The third tenet of a developmental-descriptive orientation is the *developmental* part. We take the position that the best way to decide what a child should learn next in a language intervention program is to determine where he or she is in the sequence of normal development and what the next phase of normal development for that form or function would be. In general, with some exceptions, most research in disordered language has shown that its course parallels normal development at a slowed down rate with particular, predictable asynchronies (e.g., Bishop, 1994; Leonard, 1991; Rice, Warren, & Betz, 2005; van der Lay, 2005). This finding underlies the assumption that leads us to use the normal sequence as a guide to intervention.

What does it mean in practice to use the normal developmental sequence as a guide for intervention? First, it means that we must identify where in the normal sequence a child is currently functioning, then consult the research on normal language development and find out where in the sequence the client falls for each area of linguistic behavior. We then establish goals for language intervention by identifying language skills just above the child's current level of functioning. We'll talk more in Chapter 3 about other issues involved in selecting goals for intervention. But, in principle, the descriptive-developmental approach suggests that it is the normal sequence of acquisition that serves as the curriculum guide for language instruction.

This suggests that if a 5-year-old is producing primarily two-word utterances, our immediate goal is not to teach him to produce the sentences typical of a 5-year-old but to begin work on

expanding the two-word sentences to include the next elements that would appear in normal development, such as three-word agent-action-object constructions or “-ing” marking. The same would be true for a 16-year-old with ID at the same language level. But this is not to say that the two clients would receive the same intervention. The stimuli and materials for intervention for these two clients would differ in that we would attempt to choose props and contexts for intervention that were chronologically age appropriate, even though the words, structure, and meanings being taught were similar in many ways. Let’s take an example.

Megan is a kindergartener referred for language evaluation to SLP Ms. Keene by her teacher because she used “short, babyish sentences.” Language sampling revealed that most of her utterances were telegraphic, although she used these telegraphic utterances to talk about age-appropriate ideas. After a thorough evaluation, it appeared that semantic, pragmatic, and phonological skills were relatively intact compared with her limited syntactic production, and language comprehension appeared age appropriate. The speech-language clinician decided to target three-word sentences that encoded the same meanings already expressed in the telegraphic utterances. To elicit these sentences, she used a variety of dolls and toys that she manipulated in agent-action-object sequences she expressed verbally for Megan, having Megan imitate some, providing opportunities for her to produce others, and using modeling and expansion of Megan’s telegraphic productions.

Ms. Keene also had another client on her caseload by the name of Izzy. Izzy was a teenage boy with Down syndrome placed in a special education class in the high school. Izzy also spoke primarily in telegraphic utterances, although his language comprehension skills were considerably higher than his production level. While Izzy had some difficulties with phonological production, he could generally make himself understood, and he expressed a wide range of ideas with his simple sentences, engaging often and enthusiastically in social conversation. Ms. Keene decided that Izzy, too, needed help expanding his sentence structures. But rather than using toys and dolls as stimulus materials, she used the tools and equipment that Izzy was learning to use in his vocational education program. She focused on producing sentences that he could use to talk about the work he was learning to do.

These two examples illustrate an important corollary of the descriptive-developmental approach. The normal developmental sequence provides the goals for intervention but other considerations, such as the client’s chronological age and the communicative context in which he or she must function, influence the materials and settings the intervention uses. So even if the child’s language level is preschool and the goals of intervention target preschool-level structures and functions, the materials and equipment, the particular vocabulary items, the teaching style, and context used are influenced by considerations beyond the language level, such as the child’s chronological age or functional needs

(Olley, 2005) and the functional communicative demands of the child’s environment. Targeting preschool level language structures and functions does not necessarily mean that they must be approached with a preschool style of intervention.

For the purposes of clinical practice in language pathology—that is, for diagnosing problems in the acquisition of language, detailing the parameters of these problems, and deciding what to do about them—we believe that a descriptive-developmental approach conforms best to what we know about DLD today, and provides the best guide to serving our clients. In the next two chapters, we will discuss how to implement this model in assessment and intervention for children with language disorders.

STUDY GUIDE

- I. Diagnostic Issues in Developmental Language Disorders
 - A. Define “naturalist” and “normative.”
 1. Give an example of each type of criterion as it would be used to identify a child with a language disorder.
 2. Why are both considered necessary to make a diagnosis?
 - B. Explain the differences between speech, language, and communication. How are they related?
 - C. Discuss the issue of labels in the field of speech-language pathology. What terms would you use in your clinical practice? Why?
- II. A Brief History of the Field
 - A. What field of study gave rise to the study of DLD?
 - B. Why was the development of theoretical linguistics important for our field?
 - C. How does the history of DLD tie in with issues of terminology?
- III. Aspects and Modalities of Language Disorder
 - A. What are the key linguistic features of DLD?
 - B. Name and describe the different domains of language. Imagine a child with a deficit in each domain. What would his or her conversation look like?
 - C. Which criterion would result in identifying more children with language disorder: the 10th percentile or one standard deviation below the mean?
 - D. Are there subtypes of DLD? Explain your answer.
 - E. What are the key components of the International Classification of Functioning, Disability and Health? How would you use this system in clinical practice?
 - F. What are the different levels of explanation in a causal model of disorder? How do these apply to DLD?
- IV. Etiology of DLD
 - A. How do we study language in the brain?
 - B. Why are twin studies important to understanding the biological basis of DLD?
 - C. What are some of the differences in brain structure and function associated with DLD?
 - D. Are genetic disorders impossible to treat? Explain your answer.
 - E. What environmental factors should we consider in DLD?
- V. Cognitive Models of DLD
 - A. Is DLD a disorder of language or learning?
 - B. What are the differences between “top-down” and “bottom-up” processing?

- C. Why is non-word repetition an important (and theoretically interesting) test to use in DLD?
 - D. What have intervention studies revealed about the role of auditory processing in DLD?
 - E. Is there a single cognitive explanation of DLD? Explain your answer.
- VI. Comorbidity
- A. Define comorbidity.
 - B. Describe similarities and differences between the language impairments that characterize primary DLD and those that characterize autism spectrum disorders.
- C. What aspects of literacy development are particularly vulnerable in children with DLD?
 - D. What distinguishes children with DLD who can read (i.e., decode text) from those who cannot?

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Discuss the phases and purposes of assessment.
2. Discuss the areas of assessment necessary to evaluate communication.
3. Name and define the properties, strengths, and weaknesses of standardized tests.
4. Discuss methods of assessment that are alternatives to standardized testing.
5. Describe data used and guidelines for making assessment decisions.
6. List approaches for facilitating assessment with the child who is hard to assess.
7. Discuss approaches to integrating and interpreting assessment data.

The approach to language evaluation presented in this chapter derives from the work of Jon Miller, Peg Rosin, Gary Gill, and others at the Waisman Center at the University of Wisconsin-Madison. This approach has been developed during the last four decades by these clinicians taking a developmental approach to understanding developmental language disorders (DLDs). Some of the material discussed in this chapter has been drawn from published sources (Miller, 1978, 1981, 1996) but much of it derives from their inspirational teaching and our clinical experiences of using this approach with children and their families.

GENERAL PRINCIPLES OF ASSESSMENT FOR SUSPECTED DEVELOPMENTAL LANGUAGE DISORDER

We saw in Chapter 1 that there are different ways of conceptualizing DLD: the naturalist approach, which views DLD as an impairment or disease process within the individual that disrupts functioning, and the normative approach, which focuses more on societal expectations and obstacles to meeting those expectations (Tomblin, 2008). Traditionally, clinicians coming from a medical model would adopt a naturalist approach to *appraisal*, the collection of data from a variety of sources to describe the client's condition; and *diagnosis*, the assignment and labelling of the clinical condition by means of the interpretation of standardized tests, case history information, observation, and medical examination, often with some inference about its underlying cause. From a normative perspective, on the other hand, identification of the problem and its cause are less important than understanding how the impairment influences social and behavioral outcomes for the child. As Tomblin (2008) puts it, "the causes of individual differences (environments, genes, etc.) in

language development are different from those that cause us to be concerned about some of these individual differences" (p. 95). In practice, we tend to blend the two perspectives together. The goal is to decide whether the child has a significant impairment in language form, content, and/or use, to describe that deficit in some detail relative to the normal developmental sequence of language acquisition, and to determine how this deficit will affect the child's daily activities (school, family, and social well-being). Issues of cause or the identification of a disease category are less central to the speech-language pathologist's (SLP's) mission, though we should bear in mind that we are often the first port of call for concerned parents or teachers. We should therefore be alert to the need to refer the child on for more detailed medical assessment.

Federal guidelines provided by the Individuals with Disabilities Education Improvement Act of 2004 (PL108-466), known as IDEA, make a distinction between *evaluation* and *assessment*. For clinicians working under the aegis of IDEA, *evaluation* is used to refer to the initial process of establishing eligibility for educational services. For children under the age of 6, it is not necessary to assign a diagnosis, or label, during this process, only to establish that the child has developmental delays sufficient to qualify for special educational services. Children over 6 will have to meet specific criteria for a disability as defined by IDEA in order to receive special education through the public schools. *Assessment* in this context is used to refer to the rest of the appraisal process, following the evaluation. Once a child is deemed eligible for services, clinicians need to describe communicative functioning, determine what the child needs in terms of specialist intervention and educational support, and how best to address those needs. It can be useful to think of the assessment process as hypothesis testing: the clinician forms a working hypothesis about the child's strengths and deficits based on initial observations and information from parents and caregivers. This hypothesis helps the clinician to develop an assessment plan, selecting those measures that can confirm or refute the hypothesis. The clinician may need to revise the assessment plan based on assessment results, observation of the child in different settings, or key information from another professional. But in the end, this hypothesis testing approach will yield a rich description of the child's communication strengths and needs, with clear implications for intervention and education.

The SLP almost never comes to assessment conclusions in isolation. The clinician is always working as part of a team, either with the child's family and/or teacher, or as part of a larger multidisciplinary team. Each member of the team will have expertise and unique insights into the child's strengths and needs. Putting this information together provides a more holistic picture of the child, his or her skills and deficits, and priorities for intervention and education planning. The SLP will be the expert in eliciting speech, language, and communication profiles, and answering questions about how an individual's profile may affect learning and social well-being. This information may be gathered in isolation,

or by working collaboratively with other members of the team. Whatever the method, it is important to understand the role of the other team members and recognize the value of their expert contributions to understanding the child's language disorder. Key people contributing to assessment teams are outlined in [Box 2-1](#).

Prior to meeting the child and/or family for the first time, it is necessary to review the referral letter and any other supporting documentation. When reviewing this information, the clinician needs to determine what information is already in the file and what needs to be learned during the assessment process. Basic questions to be answered include the following:

1. What is the problem, if known, in medical terms? What do other professionals (doctor, teacher, other speech-language pathologist) see as this child's area(s) of deficit?
2. When did the problem begin, or has the child always had it? Was the onset sudden or gradual?
3. Does the problem vary in severity, getting worse at some times or with some people and better with others, or is it always about the same?
4. How does the social environment interact with the child's problem? Is the child perceived as failing at school or other

important social settings? How does the family see the child and react to the difficulties?

Many agencies use a standard intake questionnaire to collect some of these data before meeting with the family. [Appendix 2-1](#) gives one example of this kind of questionnaire that is filled out by a parent before the child's first meeting with the clinician. [Appendix 2-1](#) also contains a request for release of information. Such a request must be signed by the parent and must be sent along whenever clinicians attempt to solicit information about a child from another agency. When developing an assessment plan it is wise to assemble any information available from other agencies where the child may have been a client. Including a form like this one with an intake questionnaire is usually an efficient way to find out whether the child has been seen by other professionals and to get access to the information they collected.

Case History

Once background data have been reviewed and key remaining questions have been highlighted, a detailed case history will be helpful in refining assessment plans. Techniques for clinical

BOX 2-1 Multidisciplinary Assessment Team

TEAM MEMBER	WHEN NEEDED AND ROLE
Audiologist	A referral is required for all children with suspected DLD, to ensure that there is no undiagnosed hearing impairment.
ENT	Refer to ENT for suspected cleft palate, recurrent ear infections, hearing, voice disorders, hoarseness. Will also lead assessment teams when considering children for cochlear implants.
Geneticist	Refer to a genetic counselor when a child presents with physical features that are suggestive of a genetic disorder, there is a family history of such disorder (parents, siblings or other close relatives), or a prenatal diagnosis has been made.
Learning disabilities/literacy specialist	Works in mainstream schools to support literacy development for children with reading difficulties. A key contact for school-aged children with speech and language impairment, as these children are highly likely to experience difficulties with written language.
Neurologist	Refer to a pediatric neurologist any time there is language regression, or possible seizure activity. Also likely to be involved in case management for children with Traumatic Brain Injury.
Nutrition specialist (feeding problems)	Particularly important for children with structural or motor impairments of the oral apparatus (e.g., cleft palate or dyspraxia), or neurological disorders (dysarthria, head injury). May also be required for children with ASD who have diet issues.
Occupational therapist (fine motor difficulties, clumsiness, hand movement problems)	Important for developing adaptive behaviors and daily living skills.
Parents	Key to all assessment and intervention programs. Experts in the child's development, and the environmental context in which the child will need to function.
Pediatrician	Should be kept informed of all diagnostic and therapeutic decisions as he or she has responsibility for monitoring the child's general health and development.
Physical therapist	Professional with expertise in assessing gait, gross motor skills, and clumsiness.
Psychiatrist	Likely to be involved in the assessment and treatment of children with selective mutism, anxiety, emotional/behavioural difficulties, and ASD.
Psychologist	Will provide cognitive assessment important for establishing global developmental delay, attention deficits, and managing children with selective mutism.
Mainstream teacher	It is important to liaise with the classroom teacher in order to establish meaningful language and communicative targets and to adapt curriculum and provide classroom accommodations.
Special educator	Will be involved in developing individualized education plans, modifying the curriculum, and providing individual instruction to clients with DLD.

interviewing are beyond the scope of this chapter, though detailed information is available in the work of Shipley and McAfee (2008). These authors suggest that sensitive interviewing requires mutual respect; making sure that the clients understand the purpose of the interview; listening carefully; asking clear, open-ended questions that are not leading or loaded (e.g., a loaded question might be: “you don’t scold him when he makes mistakes do you?”); and answering any questions posed by the family. Above all, the case history should highlight the family’s major concerns. It is important to remember that parents may not always see language as the primary problem, but may be more concerned about the child’s behavior, social skills, or learning and that these concerns may be related to underlying language difficulties. A case history also provides an opportunity to document any pre-, peri- or post-natal risk factors that may affect language development (e.g., drugs and alcohol, illness, hearing loss) and family history of speech, language, or literacy difficulties. The case history should also be used as a vehicle to elicit from parents clear examples of the child’s communicative attempts, what motivates the child to communicate, how the child communicates, with whom the child communicates, and what he or she does when communication fails.

The clinician should be prepared for some emotion to surface in these interviews, particularly if the family has not talked to many people about the child’s problem. The main focus of the interview should be to gather information; while a caring and accepting response to parental emotion is appropriate, dwelling on the emotion or becoming defensive if it becomes hostile is not. After expressing sympathy with the parents’ feelings, move on to a different, more neutral topic.

Low Structure Observations

As part of initial preparations for developing an assessment plan, it can be beneficial to observe the child in low structure settings. This can be achieved by engaging in free play with the child in the clinic, videoing the child playing with his or her parents or siblings, or observing the child at school or home. If the child has sufficient verbal abilities, these sessions may be supplemented by engaging the child in conversation and asking him or her to relay a favorite story or game.

During these less formal tasks, a number of observations can be made. First, the practitioner will gain an impression of the child’s expressive language abilities, including the length, complexity, and intelligibility of the child’s utterances. The clinician may also note the ease with which the child chooses words, how fluent the child is, and whether speech is coherent with a clear structure. Second, potential comprehension difficulties may be apparent in the child who fails to respond appropriately to the questions or comments of others, cannot follow adult directions, echoes what others say, or misinterprets key events in a story. Pragmatic skills may also be observed; including the child’s ability to use facial expression, eye contact, and gesture to communicate; whether the child shows toys or other materials to parents; the ways in which the child requests help, initiates and maintains conversation, requests clarification; and any evidence that he or she adapts speech style in recognition of listener needs. Finally, observation of behaviors outside the domain of language may also be informative. These may include the quality of the child’s imaginative play, attention span, gross and fine motor skills, and social interests and interactions. This set of observations provides the clinician with a working hypothesis of the nature and severity of the child’s language impairment, which can then be tested using standardized assessments.

Language or Communication Sample

Taking a sample of the child’s communication skills in less formal contexts can also be illuminating. The format of the language sample may depend on the clinical context and potential intervention approaches. For example, with a very young child with suspected autism spectrum disorder (ASD), it may be most appropriate to make a video recording of the child and parent playing together. This will allow the clinician to document how synchronous the parent and child are in their communication; as well as recording the child’s use of gesture, eye contact, communication attempts, vocalizations, and preferred play activities. The clinician may also get a sense of how well parents identify communication attempts, how they respond to these attempts, and how they naturally reinforce gesture and vocalizations with language. For more verbal children, recording a conversation between the child and his or her parents and/or clinician can give insight into articulation accuracy and fluency, diversity of vocabulary, utterance length, and grammatical complexity. Software programs such as the Systematic Analysis of Language Transcripts (Miller & Iglesias, 2008) allow for automatic calculation of a number of language variables that are useful in distinguishing speakers with DLD from their typically developing peers (Heilmann, Miller & Nockerts, 2010). Language samples have other advantages that make them a useful complement to standardized testing. First, they can be readily used with children from diverse linguistic and cultural backgrounds. Although standard metrics are not currently available for all language communities, normative data for speakers of Spanish (Bedore, Pena, Gilliam, & Ho, 2010) and African-American English (Oetting et al., 2010) dialects are being developed. Second, even without these normative data, language samples can be a useful way of documenting change, either over time or in response to intervention (Adams & Lloyd, 2005). Finally, as well as documenting articulation, vocabulary, and grammar, language samples provide a unique opportunity to survey pragmatic language skills in more naturalistic contexts. Aspects of pragmatic language such as turn-taking, initiation, topic maintenance, intonation, and reciprocity can be reliably coded and differentiate individuals with autism spectrum disorders from non-ASD peers, independently of structural language deficits (de Villiers et al., 2007; Paul, Orlovski, Marcinko, & Volkmar, 2008). These pragmatic language skills are difficult to assess using standardized tests, but will be important in formulating treatment plans. In summary, a language sample is a key component of the assessment process as it allows the clinician to gauge how the child uses his or her language for conversational exchange, to assess difficult to measure aspects of language, and can give insights into the skills and difficulties experienced by the child’s primary communication partners.

THE ASSESSMENT PLAN

As we have discussed so far, by the time a clinician begins a standardized assessment of language ability, he or she will have reviewed existing case files and requested information from other professionals working with the child, interviewed the family (and possibly the child) about the history and context of the presenting problem, observed the child during less formal activities, and taken a sample of the child’s language and communication skills in naturalistic conversation. This information should result in a working hypothesis about the nature of the language and communication

deficit, and an idea of the assessments that should be carried out to confirm or refute that hypothesis.

Some of these assessments will be carried out by the speech-language pathologist, while others may require referral to other agencies. In most instances, the clinician will want to confirm that the child does not have a hearing loss that may be contributing to language difficulties, so referral to an audiologist may be necessary. In addition, the clinician needs to determine the child's general developmental level, as this will influence the level at which to begin a communication assessment. The main question to consider is whether the child's day-to-day functioning is at or near the level we would expect given the child's age. If the client is a toddler, does the child walk, feed himself or herself, and so on? As a preschooler, does the child engage in pretend play, drawing, some self-dressing, bathing, toileting, and similar activities? As a school-aged child, is he or she placed in the appropriate grade? As an adolescent or young adult, are daily living skills (cooking, independent travel, social activities) age-appropriate? As we discussed in Chapter 1, communication skills are not usually more advanced than other areas of development, so general developmental level provides a reasonable baseline for beginning to assess communicative performance. If further assessment indicates that language and communication skills are out-of-step with other aspects of development, appropriate adjustments in the plan can be made.

For clinicians working under IDEA guidelines, the next step in the assessment process will be evaluation, determining whether the child is eligible for education services. This will usually involve some standardized testing, but will also require gathering information from parents and teachers about the child's ability to function at home and at school. This information allows us to address the "functional" criterion for eligibility, and also can highlight intervention priorities. Ways of gathering this information are discussed later on in this chapter. Clinicians will need to know what the specific eligibility guidelines for their work setting are, as these can vary from state to state and district to district. Once it has been determined that the child meets eligibility guidelines, more detailed assessment can take place.

Based on the information gathered from case history, parental interview and observation of the child, the clinician will need to decide what aspects of speech, language, and communication to evaluate. Even if the presenting problem is in only one aspect of communication, say, articulation, it is usually wise to get as much information about other areas of development as possible. Although articulation may be the most obvious problem to people in the child's environment, assessment may reveal that other deficits are involved. For instance, the child may have a hearing loss, a submucosal cleft of the palate, or a syntactic disorder that was masked by the unintelligibility. At the minimum, assessment should establish hearing level, oral-motor function, expressive language level, and comprehension of language.

It is also important to think about the order in which the assessments are done so that they provide the client with some variety and maximize his or her potential for success. We might want to start the assessment with a relatively low-structured activity, such as observing pretend play, or an activity in which the child is likely to experience success, to allow the child to warm up to the setting. Standardized tests tapping more challenging areas for the child might then follow. We might want to give the child a break and a snack while we observe oral-motor and feeding skills, and also give the child an opportunity to initiate communication with

parents or the examiner. A well thought out assessment plan often involves alternating high-structure and low-structure activities. We'll want to be careful not to put all the most difficult assessments at the very beginning, when the child may feel shy and uncomfortable, or at the very end, when the child is likely to be tired. For some children, it may be important to let them know what they will be expected to do, for example, by using a chart or simple timetable, and to think about ways to keep them motivated, for instance by putting stars on the chart after each activity, and giving stickers or free play with a favorite toy at the end of each portion of the session.

The most important thing about an assessment plan, though, is that it be *planned*. We want to get into the habit of reviewing case history and intake data and using them to make decisions about the most appropriate goals and methods for assessment. We should then write out a plan that includes the goal and methods decided upon for each area being assessed, keeping in mind that we may have to deviate from the written plan if our interactions with the child suggests an alternative course of action. A sample of a form for such a written plan is provided in Figure 2-1. Using this approach, we can ensure that we use the client's time well in the assessment, and that we will come out of it with the most comprehensive and valid information possible.

Why Assess?

Westby, Stevens, Dominguez, and Oetter (1996) identified four basic reasons for assessing language performance in a child that still motivate our assessment practices today. Each reason involves somewhat different goals and methods. Let's talk about each of these assessment purposes.

Screening

Very often in clinical practice, clients are referred for assessment because someone (usually a parent or teacher) is concerned about the child's development. This kind of referral suggests it is likely that the child's problem is interfering with daily activities to such an extent that our help is sought. However, many children who attract clinical attention have multiple developmental concerns or a particular pattern of speech, language, and communication

concerns that is obvious to non-professionals, even though it might not be the fundamental problem. For instance, children with speech sound disorders are more likely to be referred for clinical services compared to peers with similar levels of language ability who do not have problems with intelligibility (Bishop & Hayiou-Thomas, 2008). In contrast, problems with language comprehension may be “hidden” and unlikely to be noticed unless accompanied by behavioral difficulties (Zhang & Tomblin, 2000). These children with hidden language impairments are at greatly increased risk for academic failure and, in particular, reading comprehension deficits (Nation, Cocksey, Taylor, & Bishop, 2010), and it would therefore be useful to identify these children earlier in development so that we may intervene before academic problems become entrenched (Clarke, Snowling, Truelove, & Hulme, 2010).

Screening measures attempt to do this. Here, the psychometric properties of the test instrument are especially important, because a test with adequate psychometric properties is essential to provide a fair screening measure. We’ll talk more about what makes up these properties in the section on standardized tests. For now, we just need to know that a good screening test is one that meets high psychometric standards.

In addition to its psychometric properties, a good screening measure should tap a broad range of language and communication functions in the most efficient way possible. If, for example, we used the *Peabody Picture Vocabulary Test—IV (PPVT-IV)*; Dunn & Dunn, 2006) as a screening instrument, we might learn that a child does not score below our cut-off (e.g., the 10th percentile). Does that mean that the child does *not* have a language disorder? Not necessarily. A child could have a normal receptive vocabulary and still have a great deal of difficulty with expressive language skills or comprehension of complex syntax. On the other hand, we don’t want to spend significant amounts of time testing children on a full language battery before we know whether they need in-depth assessment. The *Children’s Communication Checklist—2 US Edition (CCS-US)*; Bishop, 2006b) is a good example of a screener that samples a range of language and communication skills for children aged 4 to 16 with a minimum investment of time. The *Childhood Communication Checklist—2 US (CCC-2US)* asks parents and/or caregivers to rate the frequency of both positive and negative communication behaviors, has excellent psychometric properties, and does a good job of identifying children at high risk of language impairment (Bishop & McDonald, 2009).

In evaluating the results of our screening, we need to ask whether a child who appears to have a language problem is demonstrating a linguistic difference or disorder. We need to be aware of this issue for any child who comes from a culturally or linguistically different background, such as the child from a family that speaks Spanish in the home or an African-American child whose family uses a non-standard dialect of English. For those children, whose experiences with English may be different from those of children from mainstream backgrounds, our first decision will be whether the child has a *bona fide* impairment or a communication problem that results primarily from a mismatch between the child’s experience and the expectations of the social environment. We’ll talk in detail about making this decision in Chapter 5.

If a child fails a screening measure, this does not, of course, mean he or she definitely has a developmental language disorder. Screening is used only to identify children at risk of DLD. For children who fail screening, a more extensive assessment will be needed to determine whether they meet eligibility criteria under IDEA legislation. This assessment will incorporate a range of techniques that

we will discuss throughout this chapter. A final word of caution is warranted when considering screening. In assessing children from the general population for potential language impairment, there is often potential to identify “false-positives,” or children who fail the screening measure but do not in fact have DLD. We need to be careful not to cause undue concern among parents and educators. However, reviews of screening measures have failed to identify a “gold-standard” measure that has been adequately evaluated in a population study. That’s why universal screening for DLD has not been established (Nelson, Nygren, Walker, & Panoscha, 2006). Generally, apart from screening that takes place for all children as they enter kindergarten, clients will come to us for screening because someone has noticed something is not going quite right in the communicative development.

Establishing Baseline Function

Once the initial screening question has been answered and we have determined that a child is eligible for special services, assessment is used to determine the child’s current, or *baseline level of functioning*. This purpose is distinct from the screening and evaluation functions and requires the use of different strategies and instruments. To determine baseline function, it is crucial to examine all areas of communicative function, as well as areas related to the child’s ability to use language, such as hearing, cognitive skills, and oral-motor abilities. Establishing baseline function involves finding out not only the areas in which the child is experiencing difficulty, but also identifying areas in which the child is functioning relatively well. This assessment should result in a profile of “strength” and “weakness,” such as the one illustrated in Figure 2-2. We must be somewhat cautious in using this profile, because different tests will have different psychometric properties, and will have been standardized on different populations, making it difficult to directly compare outcomes on different tests. Nevertheless, such profiles can be useful in providing a broad picture of language and communication functioning.

Establishing baseline function may require that we look at the child’s communicative behavior in several settings (that is, we may want to know more than how the child uses language in an unfamiliar place, such as the diagnostic clinic, and with an unfamiliar person, such as the SLP). Numerous authors have discussed the importance of context in observing communicative behaviour (e.g., Coggins, 1991; Losardo & Notari-Severson, 2001; Oetting & McDonald, 2002; Nelson, 2010; Westby, Stevens, Dominguez, & Oetter, 1996). This suggests that we cannot assume that one sample of behavior, gathered in the relatively strange clinical situation, tells us everything we need to know about the child’s capacities for communicating. Let’s see what this might mean in practice.

Katie was an 8-year-old girl who had been identified as language/learning disabled by her school learning disabilities specialist and SLP. Her teacher noted that she had a great deal of trouble learning to read and write and that her oral language often seemed disorganized and hard to follow. Although the school personnel did an in-depth assessment, her parents felt they wanted to know more about Katie’s problem and took her to a diagnostic clinic at the state university’s research hospital, about 60 miles from their hometown, for a multidisciplinary assessment. At her first appointment, Katie was

FIGURE 2-2 Intralinguistic profile. (Adapted from Miller, J. [1981]. *Assessing language production in children*. Needham Heights, MA: Allyn and Bacon.)

given a hearing test, some blood was taken for genetic testing, and extensive cognitive and psychoeducational testing was completed. In the last 2-hour-period of the day, Katie went to the communication disorders section for language testing.

Ms. Michaels was the SLP assigned to the case. She offered Katie a large dollhouse with a variety of furniture and characters and invited her to play with her mother and the toys. She made a video recording of Katie and her mother and prepared to take notes on Katie's language and communication behaviors. Katie played in a desultory way with the toys, then began to whine that she was hungry. When told she could have some crackers in a few minutes, she simply sat quietly and placed all the furniture in the appropriate rooms in the house without further comment.

Should Ms. Michaels conclude that Katie is minimally verbal? Clearly many factors made the day at the diagnostic center a long and difficult one. Would you like being stuck with needles for blood tests? Would you like to answer a lot of hard questions from someone you had never met before? Would you like knowing that your parents brought you all the way to this big, scary place because they think you are not doing well at school?

The point is not that clinic-gathered information is invalid. In some situations with some children it may be perfectly valid. But we do need to be aware that the context of place, person, materials, and what else has happened to the child that day can all influence performance. Whenever possible, it is to our advantage to sample a child's communicative behavior in more than one setting or with more than one person.

Just as we may want to establish baseline function by getting samples in more than one setting, we may want to get an idea of different aspects of the client's functioning. For example, we may want to know what the child's best performance is under the most ideal conditions, such as interacting with a familiar adult and engaging with novel toys in a free-play situation. But we may also

want to know something about how the child performs in more stressful situations, such as a formal testing procedure with an unfamiliar examiner, less appealing materials, and less opportunity for the child to decide how to use them. Both of these environments, the ideal and the more stressful, are "real-life" situations. The ideal situation may be more like the one encountered in the child's home, whereas the stressful one may be like what the child has to cope with at school.

When conducting an assessment, we need to be careful that we don't ignore variation in the child's functioning; knowing how a child fares under pressure will be a valuable piece of information to gather. Furthermore, it would be important to know whether there is a large gap between the child's best performance and the way he or she behaves under less than ideal conditions. So again, assessing the child in more than one situation is a key part of the assessment process.

It can, however, be painful for families to experience. When assessing the child in a formal, stressful context, the clinician may find that the child's parents are tense and anxious, and they may even complain that the testing is unfair. Parents in this situation need reassurance from the clinician that the formal testing procedure is only one piece of the information needed to understand the child's strengths and needs. Explaining that you are trying to see how the child does in this somewhat odd, unnatural situation can help to allay the parents' fears. Seeing the informal aspects of the evaluation can reassure them that their child's best performance will also be taken into account. In any case, it is always wise to explain the purpose of each phase of the assessment process to parents and to make them feel that they are partners in learning as much as can be learned about their child.

Establishing Goals for Intervention

A third purpose for assessment is to identify appropriate targets and procedures for intervention. To do this, it is necessary to reference the child's current language skills against the typical developmental sequence. Only when the child's level of functioning in each relevant area of language has been described and when all the

important collateral areas, such as hearing, cognitive level, and oral-motor functioning have been assessed, can the clinician make decisions about targets for intervention.

These decisions involve identifying the areas in which the child is functioning below expectations for developmental level. Identified areas—whether they are the comprehension of syntax or vocabulary; the expression of words, sounds or sentences, or the use of a range of different communicative functions—would then be targeted for intervention. Using the profile in Figure 2-2, the clinician is likely to target the most delayed areas of language first. When these areas of deficit are remediated to the child's highest level of communicative performance, then the target would be to improve overall language functioning so that it more closely approximates the level of language expected for the child's chronological age, or general cognitive abilities, whichever reference point is being used. Let's see how we might implement this model for a child like the one profiled in Figure 2-3.

Davey is a 6-year-old boy being evaluated for language deficits after failing a kindergarten screening. Comprehensive evaluation indicated that Davey was functioning at age-appropriate levels on measures of nonverbal cognitive ability. His receptive syntax and vocabulary scores were below the 10th percentile for his age, with age-equivalent scores of around 4 years. Expressive language was below the second percentile on all standardized measures. In addition, language sampling showed infrequent expression of communicative intentions and sentences were limited to telegraphic utterances with few grammatical morphemes. Most expressive skills were on the 2-year level. Davey's parents were initially unconcerned, as they were able to anticipate what he was trying to say and he didn't seem frustrated by his limited language skills. However, as he was now in school they were increasingly noticing that he was not as talkative as his classmates. Davey's teacher confirmed this and reported that his limited language often meant he was isolated and did not have as many playmates as the other children.

This information led the speech-language pathologist, Mr. Harper, to target expressive language skills as the top-priority objective. Goals included increasing sentence length, developing use of grammatical morphemes, increasing vocabulary through shared stories and words appropriate to classroom activities, improving articulation, and increasing the range of expressed communicative intentions. After 1 year of intervention, Davey's expressive skills were reassessed and found to approach the 4-year level in terms of semantics and sentence length. Articulation skills were at the 3-year level, but expression of communicative intentions had increased significantly. It was decided to continue working on articulation and to target some receptive skills to move these closer to Davey's chronological age level. Once receptive skills showed improvement, expression would be targeted again, to ensure expressive language skills were in line with language comprehension, providing expression had not improved spontaneously by that time.

In choosing goals for intervention, it is important to consider the priorities of the child's parents and teachers, and the communication barriers to social and academic success, but understanding the typical sequence of the acquisition of language skills is essential to making intelligent decisions about which goals to target. There is little point in working on a target that relies on foundational skills that the child has yet to acquire. For instance, it may be very important in the school context to relay a coherent narrative around "what the child did over the school vacation." But if the child has a paucity of verbs and limited expressive grammar, targeting narrative skill would be inappropriate. For that reason, gathering comprehensive and accurate assessment data is the *sine qua non* of establishing intervention goals. These data also form the basis for the next phase of the assessment process: documenting improvement during the course of intervention.

Measuring Change in Intervention

Assessment is an ongoing process. It does not end when the formal diagnostic evaluation has been completed. The SLP has an obligation to continue to evaluate the client's progress throughout the course of an intervention program.

FIGURE 2-3 Intralinguistic profile for "Davey."

First, assessment is necessary to determine whether the goals of the program have been met. How will you know when to move on to the next target of intervention without knowing whether the client has yet learned what you've been teaching? If the assessment shows that the client has mastered one of the goals of the program, the next step can be initiated. If not, perhaps the procedures or materials or the therapeutic modality needs to be changed. Programs that are not effective within a reasonable time need to be modified.

Second, ongoing assessment is necessary to decide when to dismiss a client from intervention. Just as we need to decide ahead of time on our criteria for identifying a child with a language disorder, it is important to decide ahead of time what criterion will be used for dismissal (Roulstone & Enderby, 2010). As with so many other issues in our field, there are no clear mandates for discharging clients from speech-language services. Nelson (1998) suggested posing the following questions to determine whether a client is ready to be discharged from intervention:

- Is more change needed?
- Is more change possible?
- Can more change be achieved without costs that outweigh its benefits?

To answer that last question, it will be necessary to understand what our clients and their families feel about the intervention process. Although a child may not have age-appropriate language skills, there may come a time when therapy sessions interfere with other activities (sports, dating) to the extent that the child would prefer to be discharged from therapy. Other reasons to discontinue intervention have been proposed by Fey (1986) and include:

1. The child has reached all the goals identified in the diagnostic phase of the program and is no longer viewed as having a developmental language disorder.
2. The child has reached a plateau and efforts to modify the intervention program do not achieve more progress.
3. The child is making progress, but this progress cannot be attributed to the intervention program.

Whatever criteria we use, ongoing assessment will be central to determining whether or not a child has met those criteria. It is important to remember, though, that assessment is not the only activity in which the clinician should be engaged. Most of the time we spend with clients in an intervention program ought to be devoted to teaching them to communicate better, not to test their current skills. Although the client's progress must be evaluated continually throughout the intervention program, ongoing assessment should involve only a minority of the contact time.

One other point needs to be made about assessment for evaluating progress in intervention. When looking for changes in the client's language behavior, we need to know more than whether the child can use or understand a structure or function in the clinical context, in which rules are explicit and the clinician is in control of the interaction. We also need to know whether the child can use newly acquired language and communication skills in more natural, less-structured situations. It would be unwise to discharge a client from intervention because he or she achieved 80% correct performance of the use of "is (verb)-ing" in a delayed imitation format without probing to see whether the child can use the "is (verb)-ing" structure when talking about what he or she is doing in a play context. To be valid, assessment for any

purpose must show how the child functions in naturalistic as well as structured settings. This requirement is especially important when assessing whether a child has learned what we have been attempting to teach in an intervention program. To have learned a form or function, the child must be able to use it in real communicative situations. If the child cannot do this, we have not finished our job.

What to Assess

The answer to the question "what shall we assess?" may seem simple. We assess language. But you will remember from Chapter 1 that there is a bit more to it than that. We want to ensure that our assessments will include measures of language *form*, *content*, and *use*. We will also want to consider these domains of language in at least two different modalities: *comprehension* and *production*. In typical development language comprehension and production develop in tandem, but they can sometimes come apart in DLD. We therefore cannot make assumptions about one on the basis of the other. Once we've established that the child has language difficulties, we need to assess other aspects of development that may affect language functioning or that may need to be taken into consideration when planning intervention. These *collateral areas* include, at a minimum, hearing, oral-motor functioning, general cognitive abilities, and social functioning. Let's consider these assessment challenges in turn.

Domains of Language: Form, Content, and Use

Assessment should ideally cover each of these language domains, including both understanding and production:

1. **Form (syntax, morphology, phonology):** Inflectional marking of words (plural *-s*; past tense *-ed*; third person singular *-s*); basic sentence components such as noun, verb, prepositional, adverbial phrases; sentence types, such as negatives, interrogatives, embedded clauses, and conjoined utterances. Form also includes the ability to produce sounds accurately, the consistency of sound production, and the use of phonological simplification processes.
2. **Content (semantics):** Knowledge of vocabulary; the ability to express and understand concepts about objects and events; the use and comprehension of semantic relations among these objects and events; understanding of lexical ambiguity and multiple meanings (e.g., that "cold" can refer to temperature, illness, or a personal quality).
3. **Use (pragmatics):** The range of communicative functions (reasons for talking); the frequency of communication; discourse skills (turn-taking, topic maintenance and change, requests for clarification); the flexibility to modify language for different listeners and social situations; the ability to convey a coherent and informative narrative.

Sounds like a tall order? It is. Your first response may be, "It's impossible to do all that!" But don't panic. Remember that not every aspect of language needs to be assessed using a standardized measure. Standardized testing may be used simply to establish that the child's language is deficient relative to same-aged peers. This can easily be done in a 2-hour testing session, using referral and case history information to select the areas of language most crucial to evaluate with standardized measures. And within these domains of language selected for assessment, it is important to establish the child's level of both expression and comprehension in each.

Modalities of Language: Comprehension and Production

Chapman (1978), Miller and Paul (1995), and Milosky and Skarakis-Doyle (2006) discussed the differences between children's performance on comprehension tasks that are contextualized, in the presence of familiar routines and nonlinguistic cues, and those that are decontextualized. They pointed out that children function quite differently in terms of their comprehension performance in these two settings. For example, a child with DLD may be able to follow a 3-part verbal instruction such as, "put your books away, get your coat, and line up by the door" in the classroom, because they can observe what their peers are doing and follow their actions. That same child may struggle to follow a similar instruction in a standardized test (e.g., "touch the ball, then touch the star before you touch the house"). Standardized tests measure decontextualized language comprehension, and reflect the child's language abilities under the most challenging circumstances. As an adjunct to formal comprehension testing, it can be useful to assess the child's responses in more familiar, contextualized situations. Miller and Paul (1995) suggested pairing traditional comprehension assessment with assessment of language comprehension in more naturalistic settings with nonlinguistic supports such as gesture, gaze, and other contextual cues. Comparing performance in these two settings can produce a fuller picture of the child's understanding.

Regardless of the assessment setting, it is always important to remember that comprehension is, as Miller and Paul (1995) put it, a private event, something that happens within the child's mind. We can only make inferences about the child's comprehension based on the behavioral responses to our questions and probes. If a child responds as expected, we can infer that he or she has understood the construct we are assessing. If he or she gives an incorrect response, we cannot be sure that they have not understood us; children may fail a comprehension item for many different reasons. For instance, they may have forgotten the verbal instruction, they may not have been paying attention to what we said, they may not be able to hear what is being said, or they may choose not to comply with our assessment. We therefore need to understand the additional demands of different language assessments and choose our measures wisely, so that our inferences about comprehension are as valid as possible. We'll talk more about this in the "How to assess" section.

Unlike assessment of comprehension, assessment of language production gives us direct access to how children express themselves with language. Tests that require children to repeat sentences of increasing length and complexity can be very sensitive markers of language impairment (Conti-Ramsden, Botting, & Faraher, 2001). But just as children perform differently on comprehension tests in different contexts, they may also produce language differently in different contexts. We therefore need to ensure that in addition to our standardized measures, we sample spontaneous speech in naturalistic settings in order to determine functional and ecologically valid targets for intervention.

Assessing Collateral Areas

As big as the job of assessing language function may seem, it is not the whole task of conducting an assessment. In addition to analyzing all these aspects of language, a thorough assessment also involves investigating collateral areas that relate to the child's communicative function. The SLP may not gather all this information single-handedly. In a multidisciplinary team, other professionals

may provide some of the necessary data. But even if the evaluation is conceived of as a circumscribed language assessment, it will be necessary to get this information. Upon completing the speech, language, and communication portion of the assessment, the SLP may need to request additional information from other professionals. This can be done by referring the child for further testing (Appendix 2-2).

Hearing

No language assessment is complete without an investigation of the child's hearing status. Many SLPs screen children for hearing impairment, using small, portable audiometers specifically designed for this purpose. The American-Speech-Language-Hearing Association (1997) has set guidelines for this screening. More recently, otoacoustic emissions testing has been introduced as a screening method (Hof, van Dijk, Chenault, & Atenuis, 2005). Children who fail either of these screenings need to be referred for comprehensive audiometric assessment.

Oral-Motor Assessment

Another area that needs to be assessed for any child with a language disorder is the integrity of the oral-motor system. Whenever a child presents with difficulty in expression of spoken language, it is imperative to determine whether there are physical barriers to expressive language.

Assessing the speech-motor system consists of examining facial symmetry; dentition; the structure and function of the lips; tongue, jaw, and velopharynx; and respiratory, phonatory, and resonance functions as they are used for speech. Bukendorf, Gordon, and Goodwyn-Crane (2007) and Shipley and McAfee (2008) provide some guidance in interpreting the oral-facial examination. McCauley and Strand (2008) provide a review of standardized measures for assessing oral-motor functions. Figure 2-4 provides a form that can be used to guide this assessment, derived from Meitus and Weinberg (1983) and Spriestersbach, Morris, and Darley (1991). The form is used by observing each element outlined on the checklist and marking either *yes* or *no* for each observation on the form. At the end of each section, a judgement of the adequacy of the structures and functions for speech is made. The overall ratings to be made are:

1. Normal
2. Slight deviation; probably no detrimental effects on speech
3. Moderate deviation; possible effect on speech, especially if other structures are also deviant
4. Extreme deviation; sufficient to interfere with normal production of speech, modification of structure required

To prevent the spread of infection, clinicians should always wash their hands thoroughly with soap and water, and wear surgical gloves for this examination. Hands should be washed again when the gloves are removed.

Examination of the External Face and Head

The face can be examined from a frontal view to determine alignment; spacing of the eyes; proportions of the face; and symmetry of the nares, philtrum, and Cupid's bow. The clinician can observe whether the lips approximate at rest, whether they retract symmetrically when the client smiles or produces /i/, and whether they contract symmetrically when he or she produces /u/. Details for making these observations are provided in Figure 2-4. Normal appearance and terminology for this examination are given in Figure 2-5. Observing the face in lateral or profile view, the clinician examines the alignment of the facial features again, using the guidelines in Figure 2-4. This observation can be conducted on a client of any age, including an infant.

EXTERNAL FEATURES OF FACE AND HEAD Frontal view _____ Midline of nose, philtrum, space between central incisors, midline of chin should be aligned at rest when lower jaw is opened and closed. _____ Eyes should be aligned along horizontal plane, properly spaced (face should be five eyes wide, with one eye width between bony structure that separates eyes). _____ Lower facial height (base of nose to base of chin) is greater than upper (bridge of nose to base of nose). (Use index finger on bridge of nose, thumb on base. Rotate index finger 180 degrees. Index finger should be on chin with some facial tissue below finger.) _____ Absence of septal deviations of nose. _____ Relative size and symmetry of nares, absence of deviations in columella (use inferior view as well). _____ Deep red color of inferior nasal turbinates. _____ Nares open, unobstructed breathing (for both one and two nares). _____ Philtrum. _____ Cupid's bow. _____ Lips approximate at rest. _____ Bilateral symmetry in /i/, /u/, smile. Lateral view _____ Bridge of nose, base of nose, point of chin should be in straight or slightly protruded line (class I, normal profile; if upper jaw protrudes relative to lower, class II; if lower protrudes in relation to upper, class III). Rating: 1 2 3 4 (circle) FUNCTIONAL INTEGRITY _____ Raise eyebrows. _____ Close eyelids against resistance. _____ Facial expression (smile, frown). _____ Resting posture of face. Rating: 1 2 3 4 (circle) Mandible _____ Should lower widely without deviation from midline (place index fingers in mandibular condyles; ask client to open mouth widely; fingers should fall in fossa of temporal-mandibular joint when mandible is opened; feel for symmetry). _____ Ramus should be one third shorter than body. (Place thumbs on angles of mandible, index fingers on top of condyles. Rotate index fingers to planes of mandible. One third of the body of mandible should be in front of index fingers.) Rating: 1 2 3 4 (circle)	INTRAORAL EXAMINATION Dentition (instructions to client: bite on back teeth and show gums) _____ Lower molar (or canine for children without molars) is one half tooth ahead of upper (normal, class I occlusion; if lower is one half tooth or more behind upper, class II malocclusion [maxilla is protruded in relation to mandible]; lower more than one half tooth ahead of upper, class III malocclusion [mandible protruded in relation to maxilla]). _____ One half to one third of crown of lower central incisors should be covered by upper incisor (normal overbite). _____ Upper incisors should be 1 to 3 mm ahead of lower (normal overjet). _____ Absence of missing teeth. _____ Absence of deviant spacing. _____ Absence of disturbances in axial orientation, rotations. Rating: 1 2 3 4 (circle) Pharynx _____ Absence of blockage of faucial isthmus. _____ Absence of tonsillary enlargement. Rating: 1 2 3 4 (circle) Tongue _____ Absence of structural abnormalities (lesions, scars, fissures). _____ Proportional in size in relation to oral cavity. _____ Nonspeech activities (stick out tongue, lateralize, rapid lateralization, touch nose, touch chin) to evaluate strength, range, symmetry, tone, accuracy of movement. _____ Absence of resting deviations, fasciculations. _____ Absence of restrictions by lingual frenum. _____ Functions normally during swallowing. Rating: 1 2 3 4 (circle) Palate _____ Vault. _____ Width. _____ Midline raphe apparent. _____ Absence of fistulas. _____ Posterior boundary of hard palate scalloped in appearance. _____ Boundary continuous. _____ Pink-white color. _____ Adequate midline of soft palate. _____ Single uvula. Rating: 1 2 3 4 (circle) Velopharyngeal (VP) port function _____ Absence of history of VP impairment (nasal regurgitation, family history of clefting, speech disturbance after tonsillectomy or adenoidectomy, history of speech disturbance compatible with VP problems, history of oral-facial myoneural disorder). _____ Absence of movement during prolongation of /a/.

FIGURE 2-4 Form for examination of speech mechanism. (Adapted from Meitus, I., and Weinberg, B. [1983]. *Diagnosis in speech-language pathology*. FIGURE 2-5 Surface view of lips and nose. (Reprinted with permission from Meitus, I., and Weinberg, B. [1983]. *Diagnosis in speech-language pathology* [p. 41]. Baltimore, MD: University Park Press.)

The functional integrity of the facial musculature can be observed by asking the client to raise the eyebrows, to close the eyelids against the resistance of the clinician's finger holding them open, and to smile and frown. Resting posture of the face can be observed for symmetry. Movement and proportions of the mandible

also can be evaluated, as outlined in the form in Figure 2-4. A developmental level of 24 months is necessary for the child to perform these assessments. Even a 2- or 3-year-old child may have difficulty with some of these activities, though. Young children will probably need to imitate these movements rather than produce them on verbal request. Asking the child's mother or father to imitate the clinician first and then have the child do so may be useful. Suggesting that the child pretend to be a clown making funny faces can help; so can using a mirror so that the child can see the funny faces being made. Face painting may also facilitate this assessment, but check with parents first.

Intraoral Examination

When conducting an intraoral examination, surgical gloves must be worn for the safety of the clinician as well as the child. Alignment of the teeth (normal appearance and terminology are given in Figure 2-6) and the occlusion of the mandible can be assessed using the guidelines in Figure 2-4. The eruption, spacing, and orientation of the teeth and the structure and proportion of the tongue also can be observed. Movement of the tongue can be encouraged by using a lollipop and asking the child to lick it as you place it above, below, and on either side of the child's mouth. Be sure to let the child have the lollipop when you complete the assessment, though!

The structure of the hard palate can be examined using a small penlight, noting the features in Figure 2-4 with reference to the model given in Figure 2-7. The clinician should be especially alert for signs of a submucosal cleft of the palate (Figure 2-8) and the

FIGURE 2-6 View of intraoral structures. (Reprinted with permission from Meitus, I., and Weinberg, B. [1983]. *Diagnosis in speech-language pathology* [p. 43]. Baltimore, MD: University Park Press.)

presence of a bifid uvula (Figure 2-9). These signs include a whitish appearance of the soft palate and a depression in that area that can be felt on palpating the velum. To palpate the velum, stand behind the child with his or her head resting against you as you move a gloved finger along the midline of the palate from the alveolar ridge to the velum. These findings would indicate the need for further evaluation of the velopharyngeal structures. The function of the velum can be observed by asking the child to sustain /a/ and then to produce short repetitions of /a-/a/, as indicated in Figure 2-4.

These assessments will be hard to carry out on children younger than 3 years because of their difficulty in tolerating an intraoral examination, as well as their difficulty in imitating sounds on command. To help young children with the intraoral examination, the clinician can let the child use the light to look in the parent's mouth first, then shine the light on his or her own hand to see that it does not hurt. You can ask children to open their mouths so that you can see what they had for breakfast or to see whether there are any elephants (hippos, dinosaurs, ogres) in there. Using puppets can also be helpful; the child and puppet can take turns opening their mouths, with the child playing SLP to the puppet. If the child still refuses to allow the intraoral examination, it might be best to carry on with something else, and try again once the child gets to know you better during the course of intervention.

Examination of Velopharyngeal Function and Resonance

Even if the velopharyngeal structures appear normal on inspection, it is wise to assess the child's ability to use the velopharyngeal port in speech activities. This can be accomplished quite easily with two quick and efficient instruments. The *Iowa Pressure Articulation Test (IPAT)*; Morris, Spreistersbach, & Darley, 1961) was developed to assess speech errors often associated with velopharyngeal insufficiency. This procedure can be used with children at developmental levels as low as 24 to 30 months. The words used for this test are shown in Figure 2-10; the phonemes within these words that are most important for assessing velopharyngeal function are underlined in the box. The clinician merely asks the client

FIGURE 2-7 A, The hard palate. B, Surface view of the soft palate. (Reprinted with permission from Meitus, I., and Weinberg, B. [1983]. *Diagnosis in speech-language pathology* [p. 45]. Baltimore, MD: University Park Press.)

to repeat the words and notes whether the underlined segments are produced correctly. If so, a check is placed on the line for each word. If not, the type of error is recorded, using the key at the bottom of the box. If nasal emissions, glottal stops, pharyngeal fricatives, or nasal snorts are heard, the function of the velopharyngeal port is likely to be compromised. In this case, further investigation as to the cause of this problem should be undertaken with medical consultation. Even if no structural defects can be found, a child producing errors indicating velopharyngeal insufficiency will need treatment for these errors, as well as any necessary language programming.

The degree of perceived hypernasality of speech and the absence or alteration of "pressure" consonants can be evaluated using procedures included in the Great Ormond Street Speech Assessment (GOS.SPASS; Sell, Harding, & Grunwell, 1999), an assessment specifically designed to assess velopharyngeal integrity. The sentence elicitation procedure involves asking the child to repeat sentences with a controlled number of nasal sounds. Sentences introduced by Van De Mark (1979) that can be used for this purpose

FIGURE 2-8 Intraoral view of submucous cleft palate. (Reprinted with permission from Meitus, I., and Weinberg, B. [1983]. *Diagnosis in speech-language pathology* [p. 46]. Baltimore, MD: University Park Press.)

are given in Box 2-2. The sentences vary in the number of nasal sounds included and can be used to determine whether the nasality of these sounds “spills over” to other words in the sentences. Sentences also include plosive stops that require closure of the palate for successful articulation. Atypical distortions of these consonants can be an indication of velopharyngeal insufficiency. A developmental level of about 36 months is required to perform this task. Errors are transcribed and any qualitatively atypical speech errors should prompt structural examination. If no structural abnormalities are found, speech targets for intervention could include making oral-nasal distinctions and producing plosives in connected speech.

Examination of Volitional Oral Movements

Looking at oral-motor performance in nonspeech activities can be helpful in deciding whether poor speech is related to poor tone or voluntary control of the oral musculature. Activities that can be used in this assessment appear in Box 2-3. Most children should be able to imitate most of these movements by a developmental level

of 36 months. A comparison of spontaneous and imitative oral-motor movements can be helpful in considering different diagnoses and clinicians should be alert to potential differences.

Diadochokinetic Assessment

Diadochokinetic activities can be used to observe the rate, pattern, and consistency of production of syllables. The smoothness and accuracy of the syllables produced during diadochokinetic productions can be noted by the clinician on the form in Figure 2-4. In addition, diadochokinetic rates can be tested in preschool children using the procedure by Williams and Stackhouse (2000) presented in Table 2-1. In this procedure the clinician instructs the child to “see how fast you can say these sounds.” After a demonstration and practice producing some syllables rapidly, the child is asked to rapidly repeat single syllables, such as /pΛ/pΛ/pΛ/, syllable sequences /pΛ/ /tΛ/ /kΛ/ or multi-syllabic words such as “buttercup” or “patacake.” For young children, accuracy (the number of phonemes correct) and consistency of productions across repeated items may be more informative measures of competence (Williams & Stackhouse, 2000). For older children, rate is the most frequent measurement of DDK performance (Williams & Stackhouse, 2000), in this case the time taken to produce five repetitions of the target sequence. For older children, Fletcher (1978) provided average repetition rates per second, with standard deviations, for ages 6 through 13 years. These appear in Table 2-1.

Preschoolers who have a great deal of difficulty with these tasks may be showing evidence of immaturity or apraxic features, but it is best not to jump to conclusions. With this age group, willingness and motivation can have an especially great effect on performance. To increase this motivation, you can try asking the child to pretend to be a “choo-choo” train by making /pΛpΛpΛpΛ/ sounds, a race car by making /tΛtΛtΛtΛ/ sounds, and so on. Remember, if a child performs these tasks as expected, we can conclude that other expressive language difficulties cannot be attributed to limitations in oral-motor structure or function. However, if children do not perform well on this task, we need to be careful about making causal connections; a child can fail for any number of reasons that may have little to do with oral-motor structure and function. In these cases, ongoing assessment should be conducted as the clinician gets to know the child better.

Evaluating Respiratory and Phonatory Function

In doing this assessment the clinician is again interested in determining simply whether respiratory and phonatory functions are minimally adequate to support basic speech and language. Respiratory function can be evaluated by asking the child to produce any prolonged vowel. Young children may have difficulty persisting in

BOX 2-3 Eliciting Volitional Oral-Motor Movements

AGE EXPECTED	ORAL MOTOR SKILL
6 months	Blow raspberries
18 months	Make animal sounds
24 months	Blow bubbles through straw or wand
24 months	Stick tongue out on request
24 months	Stick tongue out in imitation
24 months	Puff cheeks on request
24 months	Puff cheeks in imitation
24 months	Blow nose into tissue on request

Based on Gernsbacher et al. (2008). Infant and toddler oral- and manual-motor skills predict later speech fluency in autism. *Journal of Child Psychology and Psychiatry*, 49, 43-50.

this task for developmental reasons, rather than because they do not have adequate respiratory support for speech. If the child seems unable to sustain vowel production, he or she can be asked to pretend to be a singer and hold a long note in a familiar song or pretend to be the whistle of a train going through a long tunnel. A child who can sustain any phonation for a minimum of 5 seconds can be judged to have adequate respiratory capacity for speech.

Assessment of phonatory function has three components: volume, pitch, and quality. The ability to control volume can be evaluated by asking the child to produce speech that is very soft and then very loud. Having the child pretend to be in a church or library can help for quiet speech. Asking him or her to pretend to yell to a friend across the street or cheer for a favorite sports team will elicit loud speech. Children can be asked to demonstrate their range of pitch by imitating the clinician pretending to be a squeaky mouse and a growly bear or by pretending to be a siren with the clinician, who demonstrates the pitch variations in a siren's wail. Vocal quality can be judged in any speech activity, including in free play/conversation.

Summarizing the Oral-Motor Assessment

For the vast majority of children who are seen for limited expressive language abilities, the results of the oral-motor structure and function assessment are "unremarkable," meaning that there is no indication that any aspect of the speech mechanism is interfering with language production. Still, the SLP should be aware that such problems do arise occasionally, and when they do, they must be addressed medically, surgically, or behaviorally for the child to achieve his or her maximum communicative potential.

For some children, oral-motor deficits preclude the development of speech. In these cases, an alternative mode of communication, such as a portable computerized speech synthesizer or a letter, symbol, or picture communication board may be recommended. Most of these children have physical limitations that are associated with conditions such as cerebral palsy or severe dysarthria. For children with milder oral-motor impairments, the speech-motor assessment can help identify oral-motor strengths and needs that can be addressed in an intervention program.

It also is important to remember that the SLP is usually the only professional who will examine the oral mechanism. We cannot assume that the pediatrician, for instance, will have done so before referring a child. Pediatricians and other medical professionals note gross structural defects but may not have looked for signs of a submucosal cleft or for the functional integrity of the mechanism. That examination is the job of the SLP, and unless the child is known to have some orofacial defect or syndrome, it is unlikely that anyone else will have done an examination. Even if only 1 out of every 1000 children who present with language deficits is found to have oral-motor problems, it is our responsibility to be the clinician to identify that one child.

Nonverbal Cognition

Another piece of essential information is a measure of nonverbal cognition. A model similar to that used to assess hearing also can be followed for evaluating cognition. Although the SLP is not qualified to do IQ testing, there are informal measures of cognitive function based on play assessment, Piagetian tasks, and drawing performance. In our view, the clinician would be justified in using these informal cognitive screening measures if formal cognitive testing were not available. The clinician could simply assess whether the child is functioning at or near age level on nonverbal cognitive tasks, like those listed in Table 2-2. If a child does function

close to age level on these measures, further information might not be needed. If the child does not, though, the clinician would have a responsibility to make a referral to an appropriate professional for formal developmental testing. An example of a letter of referral for such information is given in [Appendix 2-2](#). [Table 2-3](#) lists formal IQ tests that can be requested to provide this standardized measure of nonverbal cognition for various age groups.

Social Functioning

Since communication is an interactive enterprise, we need to know something about the child's social skills and about the social environment in which children function in order to understand their language needs. We want to emphasize strongly that this does not mean that we are looking for someone to blame for the child's language disorder. Clinicians are often too quick to conclude that if a family's parent-child interaction patterns are somewhat different from those seen in a typical middle-class family, the child's problems were caused by those interactive patterns. However, it is equally important to realize that parents adapt to meet the communication needs of their children; so that changes in parent interaction styles with children who have developmental disorders may be the *result* of the child's language impairment, rather than a cause of it. Except in cases of extreme abuse or neglect, parents are almost never the primary source of their child's communication difficulty.

This part of the assessment follows from our initial observations of parents and children interacting together, and from our conversations with parents as part of the case history interview. In putting all of this information together, we need to be sure we have established:

1. How the child uses whatever communicative skills he or she has and how communication problems influence the child's development of daily living skills.
2. The child's emotional and behavioral adjustment.
3. The family's perceptions of the child's needs and their priorities for meeting them.

4. The family's strengths and needs in terms of support from peers and professionals in the difficult task of raising a child with special needs.
5. The cultural and language differences present in the home that may influence the child's communication skills or the family's perceptions of them.

Other aspects of the assessment of social environment may be carried out by a social worker in a multidisciplinary evaluation, either by using published scales or through interviews. If social-work services are not available, the SLP may simply talk with family members about their perceptions, concerns, needs, and hopes for the child. The main purpose of gathering this information is to let the family know that they are crucial members of the team in helping their child achieve the maximum level of functioning possible. It is not only the professionals who decide what the child needs to learn and how to learn it; the family has vital information about these issues that needs to be a part of the management plan. The family also has a right to help determine what goals and methods of intervention most closely meet their needs, as well as the child's, because for the child to function well, the family must be functioning well, too. And if the family are actively involved in the intervention process, there is more scope for generalization of therapy targets to everyday environments. Recent federal mandates, such those embodied in IDEA (2004) legislation, emphasize the need for family-centered intervention for young children. But all families deserve the same consideration, regardless of the age of their child. The SLP has a responsibility to establish an atmosphere in which the family feels that they are partners in the child's progress. Some questionnaire and interview instruments have been developed to assist in the assessment of social environment. These include the *Home and Community Environment Instrument* (Keysor, Jett, & Haley, 2005), the *Homelife Interview* (Leventhal, Selner-O'Hagan, Brookes-Gunn, Bingenheimer, & Earls, 2004), the *Family Strengths Profile* (Trivette, Dunst, & Deal, 1988), the *Measurement of Family Functioning* (Fewell, 1986), and the *Family Environment Scale* (Moos, 1974).

TABLE 2-2 Informal Assessments Used for Screening Nonverbal Cognition

Instrument	Age Range	Area Assessed	Comments
<i>Cognitive Assessment Battery for Young Children with Physical Impairments</i> (Guerette, Tefft, Furumasa, & Moy, 1999)	18–36 mo	Piagetian skills	Used for children with motor impairments
<i>Cognitive Abilities Scale—Second Edition</i> (Bradley-Johnson & Johnson, 2001)	3–47 mo	Infant form: exploration, communication, and initiation and imitation Preschool form: language, reading, mathematics, handwriting, and enabling behaviors	Assesses current level of functioning and identifies children who would benefit from special instruction in order to improve their abilities
<i>Developmental Activities Screening Inventory—Second Edition</i> (DASI-II; Fewell & Langley, 1984)	Birth–5 yr	Memory, seriation, reasoning, and sensory intactness	Nonverbal format for use with preschool children with disabilities; measures memory, reasoning, sensory intactness
<i>Draw-A-Person Intellectual Ability Test for Children, Adolescents, and Adults</i> (DAP:IQ; Reynolds & Hickman, 2004)	4–90 yr	Intellectual ability	10–12 min admin time. Can be administered individually or in groups
<i>Piagetian Concrete Operational Concepts</i> (Goldschmid & Bentler, 1968)	6–12 yr	Concept formation	Used for determining whether child is functioning at school-age level
<i>Piagetian Preoperational Measures</i> (Hohmann, Banet, & Weikart, 1979)	2–5 yr	Classification, drawing	Used for determining whether the child is functioning above a 2-yr level
<i>Play Assessment</i> (McCune, 1995)	8–30 mo	Symbolic behavior	Used for establishing level of representational thought
<i>Reynolds Intellectual Screening Test</i> (RIST; Reynolds & Kamphaus, 2003b)	3–94 yr	Consists of two RIAS subtests: Guess What (a verbal subtest) and Odd-Item Out (a nonverbal subtest)	Helps identify people who need a more comprehensive intellectual assessment or to document the continuing presence of intellectual deficits. 8–12 min admin time
<i>Stoelting Brief Intelligence Test</i> (S-BIT; Roid & Miller, 1999)	6–21 yr	Variety of problem-solving tasks increasing in complexity and difficulty	The examiner pantomimes the instructions and the individual responds by pointing or placing a card in the appropriate position. Provides both norm-referenced and criterion-referenced scores for IQ, fluid reasoning, and academically important subtests. 15 min admin time
<i>Symbolic Play Test</i> (Lowe & Costello, 1988)	12–36 mo	Play and symbolic ability	Used for establishing level of representational thought
<i>Uzgiris-Hunt Scales of Infant Development</i> (Dunst, 1980)	Birth–24 mo	Sensorimotor skills: object permanence, means-end abilities, imitation, causality, spatial relations, schemes for objects	Used for establishing the presence of basic intentionality and other cognitive skills related to early language

In addition, it may be useful to get some indication of the child's every day social interactions and social experiences. Several standardized instruments are available for gathering this kind of information. The *Vineland Adaptive Behavior Scales—II* (Sparrow, Cicchetti, & Balla, 2005) is a particularly well-constructed instrument that uses a structured interview format and provides norms for age groups from infants to adolescents and from mainstream as well as handicapped populations. The clinician can administer this assessment, with training provided in the test manual. In a multidisciplinary evaluation, a social worker, special educator, or mental health professional may administer it. Some additional instruments have been developed recently to assist with assessment of social

communicative skills, including the *Childhood Communication Checklist—2 US* (CCC-2US; Bishop, 2006b), the *Social Responsiveness Scale* (SRS; Constantino, 2003), the *Strengths and Difficulties Questionnaire* (SDQ; Goodman, 1997), and the *Social Communication Questionnaire* (Rutter, Bailey, & Lord, 2003). Some of these instruments consider normal variation in social behavior (SDQ, SRS) while others ask specifically about atypical social behaviors that may be indicative of an autism spectrum disorder (CCC-2US, SCQ).

Assessment of emotional status may require the involvement of a social worker, psychologist, or psychiatrist. The SLP can make a referral to these professionals when the child's behavior and

TABLE 2-3 Nonverbal Intelligence Assessment

Instrument	Age Range	Comments
<i>Comprehensive Test of Nonverbal Intelligence—Second Edition</i> (CTONI-II; Hammill, Pearson, & Weiderhold, 2008)	6–90 yr	Has computer-assisted scoring package; designed to reduce bias in intelligence assessment
<i>Hammill Multiability Achievement Test</i> (HAMAT; Hammill, Hresko, Ammer, Cronin, & Quinby, 1998)	6–17 yr	Uses eight subtests to assess verbal intelligence, overall intelligence, and yields IQ scores
<i>Hiskey-Nebraska Test of Learning Aptitude</i> (Hiskey, 1999)	3–17 yr	Developed for children with hearing impairments
<i>Kaufman Brief Intelligence Test—Second Edition</i> (Kaufman & Kaufman, 2005)	4–90 yr	Contains vocabulary subtest and matrices subtest; can compare verbal and nonverbal scores
<i>Leiter International Performance Scale—Revised</i> (Roid & Miller, 1997)	2–18 yr	Uses pantomime for instructions
<i>Merrill-Palmer Scale of Mental Tests</i> (Stutsman, 1948)	18 mo–4 yr	Useful with youngest children
<i>Naglieri Nonverbal Ability Test—Individual Administration</i> (NNAT-Individual Administration; Naglieri, 2003)	5–17 yr	Assess general ability in children nonverbally; a companion to the NNAT-Multilevel Form and is the revision of the Matrix Analogies Test-Expanded Form (MAT-Expanded Form); 25 to 30 min admin time
<i>Performance Scale—Wechsler Preschool & Primary Scale of Intelligence—Third Edition</i> (WPPSI-3; Wechsler, 2002)	2:6–7:3 yr	Part of a full intelligence scale; can compare verbal with performance scores
<i>Performance Scale of Wechsler Intelligence Scale for Children—Fourth Edition</i> (WISC-4; Wechsler, 2003)	7–16:11 yr	Part of a full intelligence scale; can compare verbal with performance scores
<i>Raven's Progressive Matrices Scale—Colored</i> (Raven, Raven, and Court, 2003)	5–89 yr (color version)	Requires only pointing response
<i>Reynolds Intellectual Assessment Scales</i> (RIAS; Reynolds & Kamphaus, 2003a)	3–94 yr	Includes a two-subtest Verbal Intelligence Index (VIX) and a two-subtest Nonverbal Intelligence Index (NIX) that taken together form the Composite Intelligence Index (CIX); 20 to 25 min admin time
<i>Swanson Cognitive Abilities Scale</i> (Swanson, 1996)	5 yr–older	Uses high interest materials to engage nonverbal children
<i>Test of Nonverbal Intelligence—Fourth Edition</i> (TONI-4; Brown, Sherbenou, & Johnsen, 2010)	5–85 yr	A language-free measure of cognitive ability; requires only a pointing response
<i>Test of Pretend Play</i> (ToPP; Lewis, & Boucher, 1999)	1–6 yr	Assesses level of conceptual development in verbal and nonverbal children
<i>Universal Nonverbal Intelligence Test</i> (UNIT; Bracken & McCallum, 1998)	K–12th grade	Memory and reasoning abilities

emotional adjustment, as observed during performance on the assessment tasks, appear to be causing problems or standing in the way of successful communication. In making these observations it is always wise to remember that the inability to communicate is a very frustrating condition. The development of maladaptive behaviors often results from being unable to express wants and needs, as we saw in the student with autism we discussed in Chapter 1. Although evaluating emotional and behavioral aspects of a language disorder is important in planning remedial programming and developing a service plan for the family, we again need to be careful about jumping to conclusions and confusing cause and effect. A child's language disorder may be a result of an emotional disturbance. This is particularly true in cases of selective mutism, when children refuse to speak in certain situations, even though they do speak in others. But it is at least as likely that difficulties in communication caused the behavioral or emotional disturbance observed in a language-impaired child.

Assessing the role of cultural and language differences again involves interviewing the parents about their expectations for communication and their own communicative styles. In some cases, an interpreter who speaks the language of the family may be needed.

This issue is discussed further when we talk about culturally and linguistically different children in Chapter 5.

How Will We Assess?

There are several methods for examining language function: standardized tests, developmental scales, interviews and questionnaires, nonstandardized or criterion-referenced procedures, and behavioral observations, including curriculum-based and dynamic procedures. Each has a place in the assessment process; each fulfills certain functions, but each also has certain limitations. The clinician's aim is to learn to recognize the right instrument to do the job at hand.

Standardized Tests

Standardized or *norm-referenced* tests are the most formal, decontextualized format for assessing language function. They are developed by devising a series of items that are given to (ideally) large groups of children with normal language development and then computing the acceptable range of variation in scores for the age range covered by the test. The advantage of standardized tests,

when they are well-constructed, is that they allow a meaningful comparison of performance among children (see Charman, Hood, & Howlin, 2008, for discussion). They do so because (ideally) they have the following properties:

1. *Clear administration and scoring criteria.* What makes a standardized test “standard” is that it is always given the same way, no matter who administers it, and it is always scored the same way, no matter who scores it or takes it. When evaluating a standardized test, it is wise to read the instructions in the manual and ask yourself whether you understand *exactly* what to do when giving and scoring the test. If questions in your mind cannot be resolved by a careful rereading of the manual, the test procedures may not be stated clearly enough to justify its use.
2. *Validity.* This refers to the extent to which a test measures what it purports to measure. A test is considered valid if its systematic error, or bias, is small. Various types of validity can be reported. *Face validity* refers to the common-sense match between the test’s intended purpose and its actual content. For example, the *Peabody Picture Vocabulary Test—IV* (Dunn & Dunn, 2006) has face validity because it asks subjects to point to pictures that an examiner names, which seems, on the face of it, to be a reasonable way to determine whether a person knows what those words mean. *Content validity* concerns whether the instrument has items that are representative of the content domain sampled by the test (Friberg, 2010). This is usually evaluated by having experts in the field judge the instrument as a whole. *Construct validity* has to do with whether the instrument measures the theoretical construct it was designed to measure. This may be evaluated either qualitatively or quantitatively and is, again, generally accomplished by soliciting expert opinion (Friberg, 2010). *Criterion-related validity* concerns whether the instrument shows strong correlations with other instruments thought to measure the same thing. There are two types of criterion-related validity: *concurrent* and *predictive*. A test has *concurrent validity* when evidence is provided that the test agrees with other valid instruments in categorizing children as normal or disordered. A test has *predictive validity* when there is evidence that this test predicts how the child will perform later on another valid measure of speech or language. These types of validity are generally considered the ones for which mathematical evidence must be presented in the test manual. Tests that do not report some quantitative data on criterion-related validity should not be considered well-constructed instruments (Friberg, 2010).
3. *Reliability.* An instrument is reliable if its measurements are consistent and accurate, or near to the “true” value. Another way to say this is that the amount of random error in the measurement is small. Reliability also can be assessed in several ways. *Test-retest reliability* involves giving the test two different times to the same person and computing the relationship of the two scores. Tests that measure high on this computation are considered *stable*. *Inter-rater reliability* involves having two different examiners either give a test to the same person or score the same person’s test. Measuring high on this attribute indicates that a test is not overly influenced by the characteristics of the examiner. Salvia and Ysseldyke (2000) suggested that both these types of validity need to be reported and that for a test to be considered reliable, both must exceed a correlation coefficient of 0.90 with a 95% confidence interval. *Internal consistency reliability* means that the subtests of the instrument rank subjects similarly, or that the parts of the test are measuring something similar to what is measured by the whole. *Split-half reliability*, where scores on the first half of a test are compared with those on the second half, and *odd-even reliability*, where scores on the odd-numbered items are compared with scores on the even-numbered items, are variants of internal consistency measures. *Equivalent forms reliability* means that two forms of an instrument (such as Form A and Form B of the *Peabody Picture Vocabulary Test—IV*, Dunn & Dunn, 2006) measure essentially the same thing.
4. *Diagnostic accuracy.* Dollaghan (2004) discussed the requirement that tests demonstrate how accurately they assign clients to diagnostic categories. When a test or other instrument is being used for the purpose of deciding whether or not a child has a particular disorder, measures of diagnostic accuracy are crucial for deciding how confident we can be about the results. This issue is often referred to as *evidence-based assessment practice*. Measures that report these statistics in their manuals provide us with the information we need to make decisions about their accuracy. Dollaghan described several measures of diagnostic accuracy, which are summarized in Table 2-4.
5. *Standardization.* This refers to a set of studies carried out to determine how the instrument works in a known population or norming sample. The characteristics of the norming sample are very important when evaluating a standardized test. The sample must be big enough, with enough individuals at each age level being tested, to permit statistical conclusions to be drawn. Most authorities on test construction (Salvia & Ysseldyke, 2000) set a minimum of 100 subjects per age group as a lower limit on adequate sample size. The sample also must be representative or contain individuals who are like the subject who will be given the test. This means that the norming sample must (ideally) be drawn from more than one geographic region, both genders, and a range of socioeconomic and ethnic backgrounds. Tests standardized in just one region or on children from a narrow range of economic or racial backgrounds will be less representative. This will mean that they serve as a fair comparison only for children who are like the ones in the norming sample. Pena, Spaulding, and Plante (2006) discussed the implications of including not only typical children, but also children with the full range of language abilities in norming samples, suggesting that if the purpose of the assessment is to identify impaired language abilities, including children with

Standardized testing is one method of language assessment.

TABLE 2-4 Measures of Diagnostic Accuracy

Term	Definition	Formula
Sensitivity (Se)	The degree to which a test accurately identifies that a child has the disorder in question; proportion of agreement between a “gold standard” of diagnosis and the test’s outcome score	$Se = \# \text{ “true positives” (those testing positive who have the disorder), divided by all those with the disorder.}$
Specificity (Sp)	Degree to which a test accurately identifies a child as NOT having the disorder; proportion of agreement between a “gold standard” of normality or absence of the disorder and the test’s outcome score	$Sp = \# \text{ of “true negatives” (those testing negative who do not have the disorder), divided by all those without the disorder.}$
Positive likelihood ratio (LR+)	The degree of confidence that a person who scores in the affected or disordered range on the diagnostic measure truly does have the disorder, or is a true positive. The higher the LR+, the more informative the measure for diagnosing the disorder.	$LR+ = \text{sensitivity}/(1 - \text{specificity})$
Negative likelihood ratio (LR–)	The degree of confidence that a person scoring in the negative (normal) range on the diagnostic measure truly does not have the disorder, or is a true negative. The lower the LR–, the more informative the measure for ruling out the presence of disorder.	$LR- = (1 - \text{sensitivity})/\text{specificity}$
Positive predictive value (PPV)	The probability that the child with a positive test result actually has the disorder. Answers the question, “How likely is it that I will be right when I classify an individual as disordered based on performance on this test?”	$PPV = \text{true positives}/(\text{true positives} + \text{false positives})^*$ *This sum equals all subjects who tested positive.
Negative predictive value (NPV)	The probability that a child with a negative test result actually does not have the disorder. Answers the question, “How likely is it that I will be right when I classify an individual as nondisordered based on performance on this test?”	$NPV = \text{true negatives}/(\text{true negatives} + \text{false negatives})^*$ *This sum equals all subjects who tested negative.

Dollaghan, CA (2004). Evidence-based practice in communication disorders: what do we know, and when do we know it? *Journal of Communication Disorders*, 37, 391-400.

language impairment in the normative sample can decrease identification accuracy. Clinicians should examine standardized tests carefully, looking for evidence of adequate size, representativeness, and the composition of the normative sample when considering the validity of a standardized test.

6. *Measures of central tendency and variability.* If a population taking a test is large enough, the scores of the people taking it will form a normal distribution, or bell-shaped curve, like the one in Figure 2-11. This is one reason why it is important for standardized tests to have large norming samples. If they don’t, the distribution of scores won’t necessarily approximate the normal curve, and they will be more difficult to interpret. When using standardized tests, we usually assume, though, that the scores in the norming population were normally distributed. When they are, most of the scores will fall close to the mean, or arithmetic average of scores for the test. This is the score that is obtained by adding up all the scores and dividing by the number of people who took the test. The further we move away from the mean in either direction, the fewer people in the population will receive that score. That’s why the area under the bell curve, representing the percentage of the population who got each score, gets smaller as we move away from the center. The mean is a measure of central tendency, or the tendency of most scores to fall near the middle of the distribution, rather than farther out toward its

tails, or ends. If we give a test to one hundred 4-year-olds with normal language function, most of them will score close to the score that is the average for the 100 scores. But how close is close and how far is far? Just knowing the central tendency measure, or mean score, doesn’t tell us when a score becomes really different from a typical score. That’s why we need a measure of variability of the test’s score, also.

Most standardized tests report, in addition to mean scores for each age group, a *standard deviation*. The standard deviation (SD) represents the average difference of scores from the mean score. It indicates how far from the mean score a typical score falls. In a normal curve, we would expect 68% of scores to fall within 1 SD on either side of the mean for the test. Half of these scores would be higher than the mean, and half would be lower. Ninety-six percent of scores will fall within 2 SDs of the mean. Combining information from the mean and SD of a test allows us to make decisions about when a child’s score falls far enough from the mean to warrant deciding that it is really significantly different from normal.

7. *Standard error of measurement.* Any score that we obtain from a client on a test is really only an *estimate* of that client’s “true” score. Unfortunately, we can never know the true score with 100% confidence because whenever we measure anything in the real world there is always some *measurement error* involved. For example, if you weigh yourself three times in

FIGURE 2-11 Relationships among derived scores and the normal curve.

one day, even on the same scale, the measurements will be slightly different. Which one of them is your “true” weight? If you’re like us, you’ll say the lowest one! But in fact, none is true. They are all estimates because of the error inherent to the act of measurement.

Measurement error happens because human behavior is never constant. Say you take a typing test. If you did so three times, again, you would get three slightly different scores. None is your true score, but all three are estimates of it. A well-constructed test takes this inevitable human variability into account by reporting a *standard error of measurement*, or SEM. The SEM represents the standard deviation that would be obtained if a person of average ability took the test a large number of times and the distribution of his or her scores were plotted. They would, theoretically, form a normal curve, like the one in Figure 2-11, with the mean being the “true” score. Sixty-eight percent of the time, the subject’s observed score would fall within 1 SD or 1 SEM of this theoretical true score. Ninety-six percent of the time, the observed score would fall within 2 SDs or 2 SEMs of this true score. In reality, SEM is computed from the reliability coefficients reported for the test. Because we can never, in practice, know a person’s true score, we use the SEM to determine a *confidence band* or *confidence interval* around the observed score. We use this band to estimate the location of the true score. The mathematical formula for this estimate is as follows:

$$\text{Confidence band for true score} = \text{Observed score} \pm \text{SEM}$$

Well-constructed standardized tests provide information about SEM in their manuals and discuss the way to use it to compute a confidence interval for a subject’s true score. These tests allow us to say with a certain degree of confidence that, based on the observed score, the subject’s “true” score falls within a certain interval. Often, tests that provide SEM information supply a graph on the test form on which this interval can be plotted as a confidence band. Figure 2-12 provides an example of the confidence band computed for a standard score of 86 on the *PPVT-IV* (Dunn & Dunn, 2006).

SEM and confidence intervals are important because they remind us that a client’s score really represents a range of probable performance, rather than a single point. They also are important for comparing performance across time. Suppose a client gets a standard score of 86 on the *PPVT-IV*. If the test manual tells us that the SEM around this score is 7 points, then with 90% confidence, or 9 times out of 10, we can say that the subject’s true score was between 79 and 93. What if we give the test after a course of intervention and find that the client’s score increased to 92? Did the intervention provide a true gain? Well, if we take the SEM into account, we cannot truly claim that it did, since the second score fell within the confidence interval for the first. To really believe progress was made, we would need to see the post-test score move above the confidence interval for the pretest. In general, because of their construction and the inevitability of measurement error, standardized tests are *not* the best way to measure change in an intervention program

(McCauley & Swisher, 1984), although they can be used if SEM information is available. We will discuss some better methods for assessing progress in intervention when we talk about other approaches to assessment.

8. **Norm-referenced scores.** Raw scores, the number of items a client got correct on a standardized test, cannot be interpreted without reference to the *norms* given in the test manual. Only by comparing the client's raw score to scores of other subjects in the norming sample does the test score acquire meaning. Three kinds of comparisons can be made: *standard scores*, *percentile ranks*, and *equivalent scores*.

a. **Standard comparisons.** These involve comparing a child's raw score with scores of children in the same population, that is, of the same age, mental age, or grade. The main advantage of these scores is that they represent equal units across the range of scores. A standard score of 85 is just as different from 100 as a standard score of 115 is from 130. This property makes these scores easy to manipulate statistically, so they are best for research purposes. They also are useful for deciding how far apart two scores (such as pre-intervention and post-intervention scores) really are. There are several types of standard comparisons:

- (1). **Z-scores.** Z-scores are simply the number of SD units that a client's score falls from the mean score for that

population. Remember that an SD unit reflects the average deviation from the mean in the norming population. In Figure 2-11 you can see that about 34% of children taking a test would, theoretically, earn scores between the mean and 1 SD above it, and 34% would get scores between the mean and 1 SD below it. So about 68% of the population, theoretically, will score within 1 SD on either side of the mean, or average, score for the test. Z-scores have a mean of 0 and an SD of 1, so a Z-score of +1 means a child scores 1 SD above the mean for his or her reference population. A Z-score of -2 means the score falls 2 SDs below the mean.

- (2). **T-scores.** T-scores are very much like Z-scores. The mean is set arbitrarily at 50 and the SD at 10. So a client with a T-score of 35 would be performing 1.5 SDs below the mean, equivalent to a Z-score of -1.5.
- (3). **Scaled scores.** Very often, a test assigns the mean score to a particular value, such as 100, and the SD to a value, such as 15 points. Many IQ tests are constructed this way, with a standard score of 100 representing the mean score and 15 points representing the SD. This form of scaled scoring is sometimes called a *deviation IQ* or *developmental quotient (DQ)*. (Recall

that IQ stands for “intelligence quotient” and is calculated by dividing mental age by chronological age and multiplying the result by 100.) That’s why a child with a mental age the same as his chronological age would have an IQ or DQ of 100: if mental age [MA] and chronological age [CA] are the same, then:

$$MA/CA = 1$$

$$1 \times 100 = 100$$

Many language tests yield DQ scores as well. On a test with this form of standard scoring, a score between 85 and 115 would be within 1 SD of the mean, clearly within the normal range. A standard score between 70 and 84 would fall more than 1 but less than 2 SDs below the mean, and so on.

- (4). *Stanines*. Stanines, or standard nines, are normalized standard scores with a mean of 5 and standard deviation of 2. Except for the two extremes (1 and 9), each stanine represents a range of $\frac{1}{2}$ of an SD. Stanines 1 and 9 include all the scores that are $1\frac{3}{4}$ SDs or more from the mean. The fifth stanine comprises the middle 20% of the distribution. The sixth and fourth stanines each contain 17% of the population, and so on out to the first and ninth, which each contain 4% (see Figure 2-11). Stanine scores are a good way to summarize a child’s performance very broadly, but they work best when a child’s score falls near the middle of a stanine. Dunn and Dunn (2006) discussed the various uses of these scores further.
- (5). *Normal curve equivalents*. These scores are often used by state educational programs as a method of reporting. Normal curve equivalents (NCEs) range from 1 to 99, with a mean of 50 and an SD of 21.06. NCEs of 1, 50, and 99 correspond to percentile ranks of 1, 50, and 99, but other NCE values do not line up directly with percentile ranks (Williams, 2006).
- b. *Percentile ranks*. A percentile rank tells what proportion of the normative population scored lower than the subject taking the test. The mean score for a test should be the score at the 50th percentile. A score at the 10th percentile would mean that only 10% of the normative sample population scored below the client’s score. Figure 2-11 demonstrates how percentile scores line up with other standard scores, by showing how the percentile scores relate to the theoretical distribution of scores in a normal curve. Percentile rank scores are easy to understand and interpret and are often very useful for discussing a child’s performance with parents and teachers. But they do not represent an equal interval scale, as standard scores do. As such, the distance between ranks cannot be assumed to be equal.
- c. *Equivalent scores*. The third kind of comparison a standardized test can make is based on equivalent scores. These classify raw scores according to a level, such as age (age-equivalent scores) or grade (grade-equivalent scores). An equivalent score represents the raw score that was the median or middle score earned by subjects in the normative sample who were of a particular age or grade. It is important to note that in equivalent score comparisons, the child is not compared with others in a similar population, that is, to children the same age or in the same grade. Instead, the

child’s score is assigned to the level representing the age or grade at which the raw score was typical. So a child who got a raw score of 55 on the *PPVT-IV*, for example, would receive an age-equivalent score of 4 years, 4 months. If this child is actually 7 years old, he is not being compared with other 7-year-olds when the age-equivalent score is reported.

The most important difference between equivalent scores and standard scores is that only standard scores include some measure of normal variation. If we need to decide whether a child’s score is *significantly* below expectations for age or nonverbal mental age, we need to know what normal variation around the test mean involves. Otherwise, we don’t know how low a score needs to go for it to represent a *significant* deficit. Let’s see how this might work in practice.

Suppose a child received a raw score of 29 on the *PPVT-IV* (Dunn & Dunn, 2006). This score corresponds to an age-equivalent of 2 years, 4 months. What if our client who took the *PPVT-IV* was 3 years, 6 months old? Clearly his score is below age level. Does that mean the child has a deficit in receptive vocabulary? We really can’t tell, because the age-equivalent score doesn’t give any measure of the normal variability seen in children in the client’s population, that is, of the same age. Perhaps that degree of variability is typical of $3\frac{1}{2}$ -year-olds taking this test. Only a standard score can tell us if the child’s performance is *significantly* different from scores of others that age. In fact, the standard score corresponding to a raw score of 29 for a $3\frac{1}{2}$ -year-old is 87, with a percentile rank of 19. This score, then, would fall within the normal range, within 1 SD of the mean for the child’s age and above the 10th percentile, and would not justify labeling the child as having a deficit in receptive vocabulary.

Remember, too, that equivalent scores, unlike standard scores, do not represent equal intervals on the scale. A 1-year delay in a 3-year-old is not the same as a 1-year delay in a 9-year-old. For these reasons, age-equivalent scores are simply *not appropriate for deciding whether a child has a significant deficit*. Only a standard comparison allows us to make the judgment that a child’s performance is significantly below the normal range. Once this significant deficit has been established, we can use the age-equivalent score as an easily understood metric to discuss a child’s functioning with parents and teachers and as a means of profiling abilities across language domains. But this is acceptable *only* when the child’s standard score can be shown to be significantly below normal. If the standard comparison measure falls within the normal range, there is no justification for using or discussing the age-equivalent score. The child is functioning within the normal range of variability on this test, and nothing further ought to be said about it. Reporting an age equivalent in this instance would be misleading.

Standardized tests, as we have seen, need to be evaluated to decide whether they meet accepted criteria to justify their use. If they do not provide clear and unambiguous instructions and information on reliability, validity, standard error of measurement, and standardized comparison scores, we are really not justified in using them since they do not fulfill the role they are purported to serve. Although some years ago it would have been difficult to find tests in our field that met these criteria, the situation is improving as we become more informed consumers of testing materials. Only if clinicians demand well-standardized instruments will the market provide them. It is our

Clinicians must carefully evaluate the standardized tests they use.

responsibility to review the tests available and choose only the best constructed. Friberg (2010); Pena, Spaulding, and Plante (2006); and Salvia and Ysseldyke (2000) provide helpful guidance for clinicians in evaluating standardized tests.

But even if a test is well constructed, can standardized tests ever provide a fair assessment? Much has been written (Bishop & MacDonald, 2009; Friberg, 2010; Spaulding, Plante, & Farinella, 2006) about the inherent dangers of using standardized tests to measure language performance. Should standardized testing be abolished entirely? Anyone who has ever had to qualify a child for services by documenting a deficit will know that standardized testing is essential for this purpose. In fact, standardized testing is the *only* valid, reliable, and fair way to establish that a child is significantly different from other children.

We can do three things to help ensure the fairness of standardized testing with our clients. The first involves choosing tests that meet accepted criteria to be considered psychometrically sound. The second entails interpreting test results properly and judiciously. If we understand the concepts involved in standardized testing outlined in this section, we will be in a position to address both these issues. The third has to do with the uses to which standardized test results are put.

Standardized tests were designed to show whether a child differs significantly from a normal population. To decide whether there is a meaningful discrepancy between the client's score and those of peers, a standardized test is the preferred method. But once that significant discrepancy has been established, other forms of assessment are necessary to establish baseline function, to identify goals for intervention, and to measure progress in an intervention program. Standardized tests were not designed for any of these purposes and they are not valid or efficient approaches for gathering this type of information. Once a significant deficit in communicative performance has been established through use of a limited number of standardized tests, other tools should be used. We'll talk about some of these other tools now.

Interviews and Questionnaires

Parents, teachers, and other adults who know a child well can provide a wealth of information to supplement our direct clinical assessment. In addition to the clinician-developed interviews and questionnaires we discussed earlier, there are a variety of instruments designed to collect information from adults in a child's life.

BOX 2-4 Examples of Standard Interview and Questionnaire Instruments

MacArthur-Bates Communication Development Inventories (Fensen et al., 2007)
Child Behavior Checklist (Achenbach & Edelbrock, 2000)
Children's Communication Checklist—2 (Bishop, 2003)
Communication and Symbolic Behavior Scales Infant-Toddler Checklist (Wetherby & Prizant, 2003)
Language Development Survey (Rescorla, 1989)
Social Communication Questionnaire (Rutter, Bailey, & Lord, 1999)
Social Responsiveness Scale (Constantino, 2003)
Vineland Adaptive Behavior Scales—II (Sparrow, Cicchetti, & Balla, 2005)

Many have the same psychometric properties of a well-standardized test, including established reliability, validity, sensitivity, and specificity. Instruments with these properties can be very helpful in the evaluation portion of the appraisal, in helping to fill out the picture of the child's level of functioning beyond what can be gathered in a clinical "snapshot." Information obtained from standard interviews and questionnaires can also be helpful in the assessment portion of the appraisal, by giving a more detailed portrait of baseline functioning than we may be able to attain in our limited time with the child. Box 2-4 provides just a few examples of these standard instruments. Additional examples are provided in subsequent chapters, for each developmental level.

Developmental Scales

Developmental scales are interview or observational instruments that sample behaviors from a particular developmental period. Usually they are not fully standardized in that they do not provide standard comparison scores, so they are not appropriate for making the initial decision about whether a child has a significant deficit in communication. But they are formal procedures in the sense that they provide some clearly stated guides for administration and usually provide some sort of equivalent score. Developmental scales such as the *Sequenced Inventory of Communicative Development—Revised* (Hedrick, Prather, & Tobin, 1995), the *Denver II* (Frankenburg, Dodds, & Archer, 1990), and the *Receptive-Expressive Emergent Language Scale—3* (Bzoch, League, & Brown, 2003) are often used by language pathologists. It would be a misuse of these instruments to mistake them for standardized tests. Because they only provide equivalent score information, they cannot be used to document the existence of a significant deficit. Once that deficit has been identified, however, these scales can be helpful for establishing baseline function by showing the general age-equivalent level at which the child is operating in the areas the scales assess.

Criterion-Referenced Procedures

Procedures devised to examine a particular form of communicative behavior, not with reference to other children's achievement but only to determine whether the child can attain a certain level of performance, are called *criterion-referenced* assessments. These are not designed to determine whether a child is different from other children. Once it is established that the child has a significant deficit, they are used to establish baseline function and identify targets for intervention by finding out precisely what the child can and cannot do with language. These procedures also are ideal for

evaluating whether intervention goals have been met. By using the intervention targets as the criteria for assessment, it can be established whether these criteria are being met in both structured and naturalistic situations. These procedures are often created by the clinician to suit the individual needs of a client, although some criterion-referenced procedures are available in commercial form. Criterion-referenced procedures can be informal and naturalistic because, unlike standardized tests, they do not have to be administered according to rigid rules. But some criterion-referenced procedures are formal and clinician-directed, as well. What distinguishes criterion-referenced approaches to assessment from the other methods we discussed is that the criterion-referenced procedures allow us to look at specific communicative behaviors in depth and to individualize the assessment for a particular child. In this way they lend themselves most effectively to remedial planning and evaluating progress in intervention. McCauley (1996) discussed in detail the characteristics and uses of criterion-referenced procedures and provided guidelines for their evaluation. Let's look at the kinds of criterion-referenced procedures that might be used for each of the two modalities of language: comprehension and production.

Comprehension

There are several reasons for developing criterion-referenced procedures to assess comprehension. We talked before about the importance of looking at comprehension skills not only in formal, decontextualized settings, but also in more contextualized situations. We also discussed looking at differences in performance between these two conditions. Criterion-referenced procedures are ideally suited to examining contextualized comprehension performance and comparing the response with the same structure in both contextualized and noncontextualized conditions. Let's look at some of the considerations we need to keep in mind when designing criterion-referenced comprehension assessments.

Avoiding Overinterpretation

When we use criterion-referenced procedures to assess comprehension, it is important to remember that we are always inferring something about a private event and we are not observing comprehension directly. That means we must be very careful not to overinterpret what we observe, particularly in the contextualized situation. If a child responds appropriately to an instruction such as, "Put the spoon in the cup," we need to remember that there is a bias toward putting things in containers such as cups. To know whether the child really comprehends the preposition "in," we will need to ask the child to put the spoon "in," for example, a shoe, or something that would be less conventionally expected.

Controlling Linguistic Stimuli

When looking at a child's understanding of language, we need to know exactly what we are testing. If we want to look at comprehension of early developing spatial terms, such as the prepositions "in," "on," and "under," it is important to be certain that any other vocabulary items used in the utterance are well-known to the child. We wouldn't ask a 3-year-old to "Put the spoon in the left-hand drawer," for example. When testing vocabulary comprehension, we need to have established that all the other words in the utterance, besides the one being assessed, are familiar. This can be accomplished either by pretesting or by carefully interviewing the parents about words the child knows.

In the same vein, we need to control the length of sentences used in criterion-referenced comprehension assessment. If we know a child uses only three to four words in his or her own sentences, we had better limit the sentences used in the assessment to near that

length. Furthermore, we need to be careful to test all structures in sentences of equal length. We shouldn't conclude, for example, that a child has difficulty understanding passive sentences if we give him "The car was pushed by the truck" and "The truck pushes the car." The passive sentence is not only more complex but also longer. If the child does not demonstrate comprehension of it, we don't know whether length or complexity is the problem. The main point is that when devising criterion-referenced comprehension assessments, the linguistic stimuli need to be thought about very carefully to make sure we are assessing what we mean to assess.

Specifying an Appropriate Response

When developing criterion-referenced comprehension assessments, the response is as important as the stimulus. As we've said, we are always inferring comprehension rather than observing it directly, so what we observe needs to be thought about carefully. Criterion-referenced comprehension assessments can use either naturalistic or contrived responses. Either way, though, it is important to specify what response will count as a success so that we clearly understand what we are looking for in the assessment.

Naturalistic responses include behavioral compliance and answers to questions. *Behavioral compliance* is an appropriate response to observe in children with developmental levels as young as 12 months. It can include touching, moving, picking up, pointing to, or giving objects and can be focused on the assessment of single words ("Give me the *shoe*." "Put it *under* the cup."); morphemes ("This is mommy's cookie."); sentence types ("I *don't* want the spoon."); or speech act intentions ("Can you open the box?"). Specifying a naturalistic response does not have to mean that the assessment involves contextualized language. Both contextualized and decontextualized comprehension can be tested in this format. In fact, it is quite important to distinguish between these two conditions when using a naturalistic response. Remember that a developmentally young child can comply with a request stated as a long, complex sentence such as, "Why don't you open this nice box for me?" But compliance does not necessarily mean the child comprehends every aspect of the form. Instead, a child might only recognize the words "open" and "box" and comply because the child expects adults to ask children to do things. Unless contextualized and decontextualized variants of a form are contrasted, it will be hard to know whether a child complies with the linguistic stimulus itself or with normal expectations for an interactive situation.

Answers to questions are another naturalistic response that can be used. Usually children will not be reliable in answering questions until they have reached a developmental level of 24 months. Answers to questions can be scored for either semantic or syntactic accuracy. Syntactic accuracy simply involves an answer in the appropriate category. If you ask a child what color an apple is and he says, "Blue," this answer is syntactically appropriate but semantically incorrect. Semantic accuracy involves an answer that would be considered meaningfully accurate by adult standards. Often children can respond with syntactic accuracy before they are entirely semantically correct. Questions, too, can be presented in contextualized conditions, as when picture referents are used or questions concern familiar daily activities. Alternatively, questions can be asked in more decontextualized forms, as with questions about events removed from the immediate situation or about objects and concepts with which the child has limited direct experience.

Contrived responses resemble those used in standardized testing. The most common contrived response for a comprehension

assessment is picture pointing. Children at developmental levels of 24 months or older can generally respond successfully to picture-pointing tasks. Single-word comprehension (“Point to the shoe.”); understanding of sentences (“Point to, ‘There are many shoes.’”); or inferential comprehension (“Which picture shows what happened next in the story?”) can easily be assessed with this format. Object manipulation is another contrived response, in which children are asked to do something to a set of objects the clinician presents. A developmental level of 20 months or so is generally required for a response in this format. Object manipulation procedures can be used to assess understanding of words (“Find the shoe”) or sentences (“Show me, ‘The boy is pushed by the girl.’”). They also can be used to assess understanding of connected discourse and inferencing ability by asking children to act out what happened in a story or what will happen next.

An additional contrived response that can be used in criterion-referenced assessment is a *best-fit* or judgment response. These types of responses involve some meta-linguistic abilities in that they require the child to evaluate language rather than merely use it. As such, they are not appropriate for children with developmental levels below 5 years. But for school-aged children they can be very effective and are easier to construct than picture pointing or object manipulation tasks. Rather than requiring a picture or set of objects to represent each aspect of the stimulus, judgment tasks can involve only two pictures, which the child uses to represent right or wrong, OK or silly, or some other dichotomy. For example, to assess understanding of passive sentences, the child might be given a picture of an “OK” ordinary-looking lady and a “silly” lady (Figure 2-13). The child can be told to point to the picture of the lady who would say each sentence. After several demonstrations of what each lady might say (OK lady: “An apple is eaten by a boy.” Silly lady: “A boy is eaten by an apple.”), the child can be asked to judge subsequent sentences. A similar procedure could be used to assess understanding of connected discourse (“Is it an OK story or a silly story?”), inferencing (“And then he ate the cake. Is that

an OK ending or a silly ending?”), speech act intention (“I said, ‘Can you pass the salt?’ and he said, ‘Yes.’ Is that an OK answer or a silly answer?”), speech style variation (“He said to the teacher, ‘Give me a pencil.’ Is that an OK way to ask?”), and other skills.

Whatever type of response we elicit, we need to elicit an adequate number of them. An important advantage of criterion-referenced procedures over standardized tests for establishing remedial goals is that standardized tests usually have only one or two items to test each structure. It can be hard to tell whether the child’s performance results from chance, particularly in a picture-pointing format in which the child can be right even if he or she is pointing randomly. Criterion-referenced procedures can include more instances for each form being tested. A good rule of thumb is to include at least four examples for each form and to require the child to get three of the four correct to succeed on that particular form. Another technique is to use contrasting sentence pairs (“A boy eats a fish.” “A fish eats a boy.”) and require that the child perform correctly on both elements in the pair. Both of these approaches can minimize the effects of random guessing.

Production

There are three major approaches to criterion-referenced assessment of productive language: elicited imitation, elicited production, and structural analysis. Because language production does allow us to observe the actual phenomena in which we are interested, issues of inferring information from what the child does are not as crucial as they are in comprehension assessment. Instead, the difficulty in assessing production is to make sure that we get a representative sample of the child’s abilities. That’s why combining these three techniques, rather than choosing among them, may be the best approach. Let’s talk about each one, then see how they might work together.

Elicited Imitation

Asking a child to “say what I say” is probably the easiest way to elicit language. We use this approach in intervention as well as in assessment to provide a model of the speech we want the child to attempt. As we saw earlier, the dangers of elicited imitation are that it may result in different kinds of errors than the child would make in spontaneous speech, and it is a pragmatically odd task; rarely in real conversations are we asked to repeat what another person says. This is true for syntactic (Merrell & Plante, 1997), phonological (Morrison & Shriberg, 1992), and pragmatic language feature imitations (Adams & Lloyd, 2005), in which case children may make changes in the imitated form, not because they could not repeat it but to render it more pragmatically appropriate. If told, for example to repeat, “The red ball is mine,” a child might say, “The red ball [or even “It” since “The red ball” would be redundant in context] is yours.” Similarly, a child might be able to repeat a sentence that he or she could not produce spontaneously. For all these reasons, elicited imitation should probably be our last resort as an assessment tool.

Elicited Production

In eliciting production we are tempting the child to say a particular thing by setting up a context in which the target form would be an appropriate remark. Rather than telling the child exactly what to say, as we do in elicited imitation, we give the child a nudge to try to get him or her to say what we would like to hear. There are a variety of ways the child can be nudged into an elicited production.

Patterned Elicitations Patterned elicitations (Lund & Duchan, 1993) involve modeling a set of similar speech productions, then asking the child to produce a new, analogous production. For example, the clinician might say, “You eat with a fork; you dig with a shovel; you write with a ____?” Patterned elicitations also can involve dolls or puppets (Paul, 1992b). For example, the clinician

FIGURE 2-13 A, Silly lady. B, OK lady.

might say, “Here’s a grouchy puppet. Whatever we say, he says the opposite. If I say ‘It’s big,’ he’ll say ‘It’s little.’ If I say ‘It’s good,’ he’ll say, ‘It’s bad.’ Now you be the puppet. If I say, ‘It’s old,’ what does the puppet say?”

Role-Play and Games Role-play is another way to elicit particular forms from a child. For example, a child can be asked to pretend to be a shy doll’s parent. The doll is too shy to answer anyone’s questions but the parent’s. To elicit question production the client “parent” is told to “Ask him if he likes cookies.” The child’s ability to produce a variety of question types can then be assessed. Games of various kinds can be used to elicit specific productions. For example, a game of “I spy” can be played to elicit use of adjectives or relative clauses. In this game, the client and clinician each look at a large, complex picture. The game involves taking turns, with one player (initially, the clinician) describing one element of the picture and the other player pointing to the element described. The clinician models the desired form (“I spy a monkey with a yellow hat.” or “I spy a monkey who has a yellow hat.”) and notes whether the child can produce it in turn.

Narrative Narrative elicitations have been shown to be a sensitive means of assessing a child’s ability to produce connected discourse (Heilmann, Miller, Nockerts, & Dunaway, 2010) and is applicable to children from diverse linguistic backgrounds (Cleave, Girolametto, Chen, & Johnson, 2010). The child can be told a simple story from a picture book and asked to retell it. Some authors have cautioned that story retelling assessments may be more valuable for their prognostic value than their diagnostic specificity (Pankratz, Plante, Vance, & Insalaco, 2007). Using an alternative procedure, a book with vivid pictures that tell a story on their own is given to the child who constructs the story from the pictures (several wordless picture books by Mercer Mayer are ideal for this purpose). Standard scoring procedures are described by Heilmann et al. (2010).

Structural Analysis

Structural analysis is the attempt to discover regularities in a spontaneous sample of communicative behavior. In structural analysis, we try to make sense of the communication the child produces spontaneously to find out what structures, forms, and functions a child uses and what contexts influence their use. There are a variety of formats for structural analysis of syntactic production (Crystal, Fletcher, & Garman, 1976; Hewitta, Hammer, Yont,

& Tomblin, 2005; Lund & Duchan, 1993; Paul, Tetnowski, & Reuler, 2007), semantic production (Condouris, Meyer, & Tager-Flusberg, 2003; Lund & Duchan, 1993), pragmatics (Adams, 2002; Bishop et al., 2000; Lund & Duchan, 1993), and phonology (Carson, Klee, Carson, & Hime, 2003; Lund & Duchan, 1993; Morris, 2009; Shriberg & Kwiatkowski, 1980). Some of these are discussed in Heilmann, Miller, and Nockerts (2010). We’ll talk in more detail about structural analysis in some of the later chapters.

Structural analysis involves eliciting a representative sample of communicative behavior, as described in Table 2-5. Some additional suggestions for “good talking” to young children, include the following:

1. *Be patient:* Don’t overpower the child with questions or requests. Give space and time for the child to talk. Don’t be afraid of pauses.
2. *Follow the child’s lead:* Listen to what the child is saying and maintain the child’s topic and pace. Don’t rush on to the next topic or activity.
3. *Don’t ask silly questions:* A good conversational partner has something worthwhile to say. Don’t ask questions to which that the child knows you already know the answer.
4. *Consider the child’s perspective:* Try to see things, such as the assessment situation, from the child’s point of view. Take cognitive level and awareness of time, space, and motivation into account. Give the child’s comments your undivided attention and respond positively to them. Be warm and friendly.

As the sample is being collected, we will want to record it. Recording the sample allows us to examine it in more detail than we could if we had to get all the information from it in real time. Video recordings are the recordings of choice these days, as the quality is good enough to focus solely on speech, if desired, but can also be used when a nonverbal context is necessary to decipher meanings, to explore nonverbal aspects of communication, or to observe other behaviors that accompany speech or language difficulties. The recorded sample is then transcribed at whatever level is appropriate for the analysis being done. Semantic and syntactic analyses require word-by-word transcriptions of the client’s speech, probably with the linguistic context of the other speaker’s remarks included. Phonological analysis requires phonemic transcriptions and in some cases phonetic level information, as well. Pragmatic analysis

TABLE 2-5 Suggestions for Eliciting a Representative Speech Sample from Children

Developmental Level	Materials	Sample Type
12–30 months	Familiar and unfamiliar toys; several examples of balls, dolls, eating utensils, cars, etc.	Child-centered conversation on here-and-now topics
30–48 months	Pretend play materials, such as dollhouse with people, furniture, etc.; introduce some topics about absent objects, people, and events removed from the immediate context in space and time, such as holidays, vacations, etc.	Child-centered conversation on both here-and-now and there-and-then topics
4 years and older	Pretend play with miniatures, unusual objects to describe, photographs of events/places	Object description, picture description, narration of personal experience
5–10 years	Wordless picture books, pictures of different “topics” (dentist, school, sports)	Personal narratives, story retelling, or story generation from picture book
10 years and older	Favorite Game or Sport task: child asked to tell the clinician about a favorite game/sport and how to play it	Expository discourse

Language sampling ensures validity of expressive language assessment.

necessitates some information about the nonlinguistic context and perhaps about paralinguistic cues that accompany the speech. The sample is then analyzed not only for errors but also for evidence of patterns or regularities that can be used to identify the child's level of communication and to describe the rules and contexts that influence production. We'll talk in more detail about the methods for analyzing language samples in subsequent chapters on assessment at a variety of developmental levels.

Integrating Approaches

Structural analysis is no doubt the most valid way to look at a child's productive language, since we are observing the very thing we are interested in assessing: spontaneous speech for communicative purposes. One drawback of this approach, though, is that the child may not spontaneously produce all the aspects of language that interest us. When talking to an unfamiliar adult, for example, a child may be unlikely to produce questions and negative forms, for pragmatic reasons. If these forms simply do not appear in spontaneous speech, how can we know the child's skills in these areas? The advantage of criterion-referenced assessment is that we can combine approaches as needed to give us access to additional information. One strategy for doing a criterion-referenced production assessment would be to collect a sample of spontaneous communication; record, transcribe, and analyze it; and identify any structures or functions of interest that did not appear in the sample. We could then use an elicited production procedure to try to get some evidence about these forms. If the child still failed to "take the bait," a direct elicited imitation might be tried.

Behavioral Observations

Criterion-referenced assessment and structural analysis allow the clinician to examine a child's communicative performance in detail without the restrictions and limitations imposed by standardized testing. With criterion-referenced procedures, however, we are still comparing the child's performance with a predetermined criterion to decide whether the child is meeting this criterion or whether the child needs intervention to accomplish this goal. Behavioral observations differ from this approach in that they are not concerned with comparing a child's performance with a criterion, but only with describing performance in a particular area. Behavioral

observations are used to sample whether a particular behavior of interest occurs, the frequency with which it occurs, and the context or antecedents likely to be associated with it. Behavioral observations commonly are designed by clinicians and involve checklists or rating forms that are used to examine or count particular behaviors. Figure 2-14 gives an example of a behavioral observation form that might be used to examine communicative competence in a child suspected of language disorder. This form was adapted from one developed by Erickson (1987).

The most important aspect of behavioral observation is carefully defining the behavior or behaviors that we want to observe. This means that we must target areas for behavioral observation before we begin the assessment by determining which aspects of the client's communication will be difficult to assess through any of the other methods we've discussed. While standardized and criterion-referenced procedures are useful for looking at language behaviors for which there are well-established norms or comparison data, behavioral observations are suited to those behaviors for which less normative data exist, for which somewhat subjective judgments must be made, or for which standard comparisons are not usually done. For example, computing a mean length of utterance in morphemes in a criterion-referenced structural analysis is a relatively objective, straightforward procedure, one for which some normative data are available. If we want to examine the structural complexity of a child's speech, computing a mean length of utterance in morphemes is a reasonable approach. But what if we want to know how frequently a child responds inappropriately to questions, using either verbal or nonverbal responses, rather than how complex a child's utterances are? The answer to this question might be important if it were part of the initial referral, for example. In this case, a behavioral observation could be done, in which we ask the child questions in a naturalistic format, such as having him or her describe to the examiner illustrations in a picture book and then counting the number of appropriate and inappropriate responses. The observation would give some quantitative information about a communicative behavior and could serve as a baseline for evaluating intervention directed at reducing inappropriate responses.

A second important consideration in devising behavioral observations is to use a recording system designed for the purpose. Performing a behavioral observation does not mean just sitting and watching a client behave. A recording document that contains a way to collect quantitative data about the behavior of interest must be used. The form may allow the clinician to rate the frequency of a particular behavior, as the form in Figure 2-14 does, or it may allow the clinician to rank a behavior on a scale. The rating used in the oral mechanism assessment in Figure 2-4 is an example of this type of observation. The form also could be simply a checklist in which the existence of a particular behavior is noted. For example, the list of articulation errors associated with velopharyngeal insufficiency in Figure 2-4 could serve as a checklist. A child's spontaneous speech also could be rated for these types of errors. The errors could simply be listed on a sheet and a check placed by each if it were heard in the sample. An assessment like this might be important if we need to determine whether the child is using errors in naturalistic conversation that have been eliminated in structured settings by intervention. The main thing to remember about behavioral observations is that we are never justified in doing them unless we know exactly what we will be looking for and have developed a form or document to serve as a record for the observation. Such a document is important not only for organizing our observations, but for being sure that another

I. Discourse skills				
	Frequently Observed	Occasionally Observed	Not Observed	Examples
Starts a conversation				
Shows listening behavior				
Responds with appropriate content				
Interrupts appropriately				
Stays on topic				
Changes topic				
Appropriately ends a conversation				
Recognizes listener's viewpoint				
Demonstrates topic relevancy				
Uses appropriate response length

clinician could readily observe the same behavior in the same way. This ensures that progress over the course of an intervention program can be reliably charted. Let's talk about several specific types of behavioral observations that can fill particular "niches" in our overall appraisal.

Dynamic Assessment

All the assessments we have discussed so far fall under the heading of "static" procedures. Such static assessments describe current level of performance by holding contextual support to a minimum. In contrast, dynamic assessment is designed to manipulate context in order to support the child's performance so that an optimal level of achievement can be identified (Olswang & Bain, 1996). Lidz and Peña (2009) characterize dynamic assessment as a "pretest-intervene-posttest" format, and similarities between dynamic assessment and response to intervention approaches have been discussed (Griogorenko, 2009; Lidz & Pena, 2009). In dynamic assessment, the clinician actively engages a child in a learning situation that allows observation of the client's learning process and then attempts to promote change. Children are encouraged to think out loud throughout the session and to analyze their learning processes. The outcome of a dynamic assessment is not a score. Instead, it can be described with the following three kinds of information used in assessment planning:

- How the child approaches tasks; error patterns and self-monitoring abilities

- The degree to which the client's behavior is modifiable in response to interventions
- Intervention styles and methods that will have the greatest potential to promote change

Functional Assessment

In Chapter 1 we discussed a framework devised by the World Health Organization to consider not only the child's impairment, but the impact of that impairment on the child's ability to participate in activities or experiences. Functional assessments are designed to measure those impacts in a structured way, and may also gather information about the contextual factors that support or hinder the child's communicative progress (see Table 1-2). Several tools are available for this enterprise, such as the Communication Supports Checklist (McCarthy et al., 1997). These measures are discussed in more detail in subsequent chapters.

A second form of functional assessment was presented by Campbell (1998). He argued that we need to go beyond our traditional assessment of positive change in the specific communication behaviors addressed in the intervention program. *Functional assessment* here refers to the evaluation of the ways in which these newly learned communicative behaviors increase a client's level of autonomy in real-life situations. To accomplish this assessment, he advocated rating a child's use of communication in everyday life on six basic parameters. These parameters were identified by reviewing treatment summaries of children in intervention to identify the most

common goals and most frequent parental expectations. Campbell developed a form, similar to the one in Figure 2-15, to be filled out by both the clinician and the parent at the first and last intervention sessions. Using a form like this, it is possible to establish not only that specific communication behaviors have changed as a result of intervention, but also how these changes impact the perceived communicative competence of the child.

Curriculum-Based Assessment

Curriculum-based assessments (CBAs) are frequently used in school settings. They may be constructed by teachers, SLPs, and other professionals to reflect the content of the curriculum. CBAs can be used effectively to assess curriculum-based language use and may be more sensitive to tracking the progress of students from culturally and linguistically diverse backgrounds than traditional standardized testing (Hosp, Hosp, & Howell, 2007; Losardo, Notari-Syverson, Coleman, & Botts, 2008). You may hear various terms used in reference to these methods, including *authentic assessment* and *performance assessment* (Damico, 1993), *artifact* or *portfolio assessment*, because data collected about a client’s performance often include various artifacts (examples of written work, projects, language samples, etc.) organized into a portfolio. Scoring rubrics are frequently used to make judgments about the degree to which the performance demonstrates the desired behavior or skill (Kennedy, 2007). We’ll talk in more detail about these kinds of assessment in Section III, on school language and learning disabilities.

Formative versus Summative Assessment

As we noted earlier in the chapter, assessment is integral to our work as SLPs and the process of hypothesis testing with our clients. We’ve also noted that assessment can serve many different purposes. It may be helpful to think of assessment activities as falling into two broad categories: formative and summative. A formative assessment is defined by Norcini et al. (2011) as “low stakes, often informal and opportunistic in nature, and is intended to stimulate learning” (p. 211). This is the type of assessment we’ll be doing throughout our intervention program, enabling us to track progress and provide the child with scaffolded feedback designed to increase learning of speech, language, and communication targets.

As such, Norcini et al. suggest that formative assessment works best when it (1) is embedded in the learning process, (2) provides specific feedback that leads to explicit behavioral change, (3) is ongoing, and (4) is timely.

Summative assessment, on the other hand, is defined by Norcini et al. (2011) as being “high stakes and is primarily intended to respond to the need for accountability” (p. 211). This is the type of assessment we will be doing for diagnostic purposes, to measure baseline performance and change in performance after a period of intervention. As such, summative assessment often requires more structured or standardized assessment material, and a systematic administration procedure. Although feedback to the child and/or family is desirable after any assessment, the goal of the feedback in this case is not to affect immediate communication change, but to summarize the child’s strengths and needs, and the progress made during intervention.

THE HARD-TO-ASSESS CHILD

Many children can cooperate with a clinician for an extended period so that assessment goes smoothly and quickly, but some cannot. In the course of a diagnostic career, every clinician encounters children who are hard to assess. Some clinicians call these children “untestable.” Their clinical report on these youngsters may simply state that the child was unable to cooperate with any testing, so diagnostic information could not be gathered. Our position is that no child is untestable and that, using a variety of clinical tools, it is possible to get at least some useful diagnostic information about every child, regardless of how hard he or she may be to assess.

When clinicians say a child is untestable, they usually mean that the child does not respond to standardized tests. But remember that standardized tests are only necessary to establish that a child is significantly different from other children. This is usually easy enough to do in a hard-to-assess child. Even if the clinician feels that the standardized test results underestimate the child’s true ability, the fact that the child falls below the cutoff is enough to qualify the client for further assessment. From then on,

Please answer the following questions about your child's communication. Please check the box of the number that best describes your child's current abilities.

	1 (Never)	2 (Rarely)	3 (Sometimes)	4 (Almost Always)	5 (Always)

Your child successfully communicates wants and needs to others without speaking (e.g., using gestures, signs, facial expressions, communication devices)	☐	☐	☐	☐	☐
Your child communicates successfully with peers	☐	☐	☐	☐	☐
Your child's speech can be understood by unfamiliar listeners	☐	☐	☐	☐	☐

FIGURE 2-15 Functional assessment of children’s communication. (Adapted from Campbell, T.F. [1988]. Measurement of functional outcome in preschool children with neurogenic communication disorders. *Seminars in Speech and Language*, 19[3], 223-233.)

criterion-referenced and behavioral observation procedures can be used. These are less formal and can be adapted to the needs and interests of the child. In addition, if the child refuses to participate in standardized testing at all, standardized interview and questionnaire procedures, such as the *Vineland Adaptive Behavior Scale—II* (Sparrow, Cicchetti, & Balla, 2005), can be used to get a norm-referenced score based on parent report. Again, this can confirm the child's significant difference from peers, and less formal methods can be used to establish baseline function and identify goals for intervention.

Nelson (1991) discussed four kinds of children who may be hard to assess: children who are extremely shy and quiet, those who are noncompliant, those who are hyperactive and impulsive, and those with physical handicaps. For *shy* children, slowing down the pace of the assessment, giving more time to warm up, and starting with comprehension procedures that require little speech on their part can be helpful. A clinician can use misnaming of common objects and playful violations of routine to get these children to engage in criterion-referenced and behavioral observations.

For both *noncompliant* and *hyperactive* or impulsive children, setting a tone of firm control on the part of the clinician and perhaps asking the parent to wait in an observation room rather than within the child's view may be useful. Nelson (1991) suggested using time-out procedures to gain the cooperation of the noncompliant child. This may require making the assessment longer than planned, but it often results in the ability to get some valid information about the child instead of having to give up in defeat. Avoiding language that gives the child power over the clinician—such as asking the child, “Do you want to do X?” or following a command with “OK?”—can prevent awkward situations in which the child takes the clinician up on the apparent opportunity to reject what the clinician has proposed. Removing extraneous stimulation from the environment can help the hyperactive child focus on the assessment materials. Being flexible about where to do the assessment also can help with this type of child. Instead of insisting that he or she sit at the table, the clinician can do some of the assessment on the floor, in the hall, or under the table. Nelson also suggested taking frequent breaks and doing the assessment in small chunks of time rather than in one extended period.

The child with visual or other *physical disabilities* also presents special problems because of the inability to respond to the usual assessment stimuli in the usual way. Children with physical disabilities who cannot point may be asked to look at the stimulus that best matches what the clinician says. Those with no speech can be given several different alternative communication modes, such as pictures, Blissymbols, signs, or written words, in a dynamic assessment approach to determine what helps them to communicate best. Blind children may be asked to name or describe objects that they feel or to tell about events that they have experienced.

Nelson (1991) provided additional suggestions for working with the hard-to-assess child. The important point is for the clinician to know that something can be learned about every child with a communication problem, even if standardized testing does not seem the most fruitful source of information. In our opinion, we are never justified in writing off a child as “untestable.” By making use of our complete repertoire of assessment tools, it is possible to decide for every child whether there is a communication problem, to establish baseline function, and to determine what the child needs to communicate better. This is our mission and, difficult though it may be, it is never impossible.

INTEGRATING AND INTERPRETING ASSESSMENT DATA

Once the interviewing, testing, and observations have been completed, our next task is to interpret the meaning of the assessment data. If a significant deficit is identified by standardized testing, the standard score comparisons may be converted to age equivalents. These can then be combined with information from developmental scales to create a profile of strengths and weaknesses, such as the one in [Figure 2-2](#). The profile can be used to plan what kinds of additional criterion-referenced assessments and behavioral observations may be needed to complete our picture of the child's current level of functioning. This information may be gathered in subsequent assessment sessions or during the early phases of the intervention program. What we do *not* want to decide on the basis of the standardized testing is that we need more standardized testing. Once we have determined that the child has a significant deficit in communicative performance, the important task is to establish baseline functioning in the various areas of language. Interviews, questionnaires, criterion-referenced procedures, and behavioral observations, including functional, dynamic, and curriculum-based methods are better suited to this purpose.

When the child's communicative profile has been established and the baseline level of functioning has been outlined, this information is used to complete the final three parts of the appraisal process: determining the severity of the disorder, making a prognostic statement, and making recommendations for an intervention program.

Severity Statement

Based on the assessment data, a decision is made by the clinician as to the degree of severity of the child's communication disorder. Generally, severity is labeled as mild, moderate, severe, or profound. The World Health Organization has provided guidelines to the use of each of these terms, which are summarized in [Table 2-6](#).

Severity ratings are important for two reasons. First, they help to establish priorities for intervention. If communicative deficits are severe, whereas deficits in other areas assessed by the multidisciplinary evaluation are less severely affected, then priorities for intervention should include speech and language services. Conversely, if communication is less severely affected than other areas, such as social-emotional development or behavior regulation, these areas might take precedence for intervention resources. The second purpose of the severity rating is to have a benchmark for evaluating the effectiveness of intervention. If communicative skills are initially assessed as severely impaired and after several years of intervention the severity rating improves to moderate, this is one way to establish the effectiveness of the intervention, even though fully normal functioning has not been achieved.

Prognostic Statement

The prognostic statement contains the clinician's prediction about what communicative outcome can reasonably be expected at some future time, in light of the current level of functioning. Prognostic statements are similar to severity statements in that they help us to economize intervention resources and aid in accountability. If a

TABLE 2-6 Severity Classifications

Classification	Description
Mild	Some impact on performance but does not preclude participation in age-appropriate activities in school and community Able to function independently with minimal assistance
Moderate	Significant degree of impairment that requires accommodations to function in mainstream settings Able to function in a supervised setting
Severe	Extensive support required to function in mainstream settings May demonstrate some functional skills with supervision
Profound	Few functional skills Requires maximum assistance with basic activities

(Data from Accardo, P., Whitman, M. (2004). *Dictionary of developmental disabilities terminology* [2nd ed.]. Baltimore, MD: Paul H. Brookes; World Health Organization. [2004]. International statistical classification of diseases and related health problems [10th ed.]. Geneva: Author.)

clinician states in the prognosis that a child has the potential to achieve normal communicative function, this statement can serve, again, as a benchmark against which to measure progress in intervention. If the child fails to achieve the level of function predicted in the prognostic statement after a reasonable time in intervention, either the prognosis was wrong or the intervention has not been as effective as it should have been. In either case, an accounting of the discrepancy is necessary.

For this reason, we need to be cautious when making prognostic statements, taking all relevant factors into account. Age is usually important in prognosis. The younger a child is when a communication disorder is identified, the less certain the outcome. A teenager with no functional speech has a much clearer and poorer prognosis than a 2- or 3-year-old who has not begun to talk. The social environment can affect prognosis as well. A client from a well-functioning family that has the resources and energy to work with and advocate for the child has a brighter prognosis than a child from a family in which the parents are ill, addicted to drugs or alcohol, or overwhelmed by a struggle for economic survival. The client's personality and temperament, too, have an effect. A careful, reflective child who has well-developed attentional capacities is in a better position to take advantage of intervention than a hyperactive, impulsive child, who must acquire basic attending behavior before much learning can take place. Similarly, a child who is highly motivated to improve because he or she has a lot to communicate and is willing to take some risks and make some mistakes has a better prognosis than an extremely cautious, shy child who is relatively self-sufficient and does not feel strongly impelled to overcome the communicative deficit. The involvement of other areas of functioning beyond communication also affects prognosis. A 3-year-old with mental retardation and autism who does not talk generally has a worse prognosis than does a sociable nonspeaking 3-year-old with normal cognitive function. Issues of prognosis for various conditions associated with language disorders are discussed in more detail in Chapter 4. Again, the clinician must evaluate each aspect of the prognosis throughout the course of the

appraisal, making use of data from interview and observational sources. The clinician's impressions of these elements will be factored into the prognostic statement.

Despite using the best and most extensive data available, though, when we state a prognosis we are always making an educated guess. Whether we make a prognostic statement in writing, in a clinical report, or in conversation with the client's family, this fact has to be respected. It is usually best, then, to make a short-term rather than long-term prognosis and to talk about what it is the child *will* likely be able to do over a specified period, rather than what he or she won't be able to do. For example, a prognosis might contain a statement that with intensive intervention the client will move within 1 year from single-word utterances to the production of some two- and three-word sentences. This prognosis can be evaluated, since it states a specific time period and a measurable outcome. This prognosis also is preferable to one that states that a client will not achieve normal expressive language development, for example. This contains no time period over which an evaluation can be made and states only a negative outcome, not what *can* be expected to happen.

Clinicians who adhere to the rule of making short-term prognoses and stating them in positive terms usually encounter less resistance and hostility from families than those who make blanket long-term projections of which, in truth, no one can really be sure. Even when pressed by a family to predict what the child will be like as an adult, the wise clinician can remind the parents that the important task is to help the child do the best he or she can *now* and for the next few months or years. An honest admission that human beings are too complicated and unpredictable for us to foretell their future can be coupled with encouragement for the family to work with the child as he or she is now and to advocate for the services he or she needs to achieve the next appropriate developmental step. An assurance that diagnosis and prognosis will be ongoing can help the family to cope with the uncomfortable uncertainties of raising a child with disabilities.

Recommendations

The last, but certainly not the least, task of the diagnostic process is making recommendations for intervention. These recommendations draw directly on the assessment data. When we talked about the "why" of assessment, we discussed the establishment of goals for intervention as one of the central purposes of the appraisal. In making recommendations, we incorporate the establishment of goals for intervention into a more general statement about the need, directions, and approach to intervention that would be most appropriate for this particular client. The statement of recommendations, then, in either the clinical report or in conference with the family contains three parts:

1. Our recommendation as to whether some intervention by an SLP is appropriate at all. This recommendation is based on whether the child has a significant communication disorder and whether we believe, as a result of the severity and prognostic statements, that intervention would be helpful.
2. The goals we have established for intervention, based on the assessment data and intralinguistic profile.
3. Suggestions for methods, approaches, activities, reinforcers, or any other aspects of the intervention program that the clinician believes would be informed by the data gathered during the assessment. This is the clinician's chance to share the observations and insights gained from working with the child that would help to maximize chances for success in intervention.

Putting It All Together: The Clinical Report

A clinical report is simply a summary containing all the information we have discussed in this chapter. Generally, the clinical report follows a more or less standard format, such as the one given in outline form in [Box 2-5](#). [Appendix 2-3](#) provides a sample of a clinical report. The report starts by stating basic identifying information, such as client name, age, date of birth, address, phone number, parents' names, referral agency, and so on. The next section contains a short statement of the presenting problem or complaint. This is followed by a brief review of the historical data. The next section of the report is usually labeled "Assessment" or "Examination Findings" and contains the standardized tests given and the standard score comparisons. Other assessments also are summarized briefly. The next section, entitled "Impressions" or "Behavioral Observations" is where the clinician states some of the insights that come out of working with the child, such as the clinician's opinion about factors in the child's social environment or temperament that may influence current functioning or success in an intervention program. In the "Summary" section, the clinician interprets the findings, saying what, in aggregate, the appraisal data mean. This section also generally contains the severity and prognostic statements. The "Recommendations" section should contain the three points we discussed previously.

The language in the clinical report should be clear and simple, but professional. It is not necessary to use every technical term we know or to repeat every confidence expressed in the interview. The purpose of the clinical report is to convey as succinctly as possible the information gleaned from the assessment and to do so in a way

that both parents and other professionals will find easy to understand. Toward this end, the use of some personal pronouns (I, we, etc.) is acceptable and would generally be preferred to awkward usages, such as "this clinician found. . . ." In general we want to avoid qualifiers, such as "rather" and "very." We need to distinguish between information we gathered or observed ourselves from information reported to us by parents or others, so it is appropriate to use phrases such as, "according to parent report," or "the mother recalls." It's best to avoid judgmental terms such as "good," "poor," "nicely," etc. in describing a child's performance. Usually sentences in active voice are better than passives, although passive sentences can be used occasionally. Short sentences are usually better than long ones. Each new thought should have its own sentence. Keeping the noun and verb in each sentence close together is a good rule. This helps to keep the sentence from getting too strung out and complicated. Jerger (1962, p. 104) provides good advice when he tells us to "write it the way you would say it." We can think of the report as a conversation, in which we try to tell another person who is not an SLP what we saw in this child. This image can help us to choose the words and sentences that work hardest to get our meaning across.

CONCLUSIONS

The assessment process provides the backbone of our intervention program. It tells us whether we need to intervene and what the targets of intervention need to be, and it allows us to decide whether intervention has been effective. The clinician should be familiar with a variety of tools, both formal and informal, for gathering assessment information and must choose these tools carefully to make the most of the time spent assessing the child's skills. The speech, language, and communication assessment is usually part of a larger process that may require the clinician to communicate findings to other professionals and to request further information. The assessment is best considered as a process of hypothesis testing: formulating a hypothesis about the nature of the child's difficulties and testing that hypothesis using both assessment data and response to intervention. In this way, clinical decision making involves asking a number of questions and ruling out alternative explanations based on the answers we find to those questions. This decision making process has been illustrated by Bishop (2001) and is schematized in [Figure 2-16](#). In communicating our decisions to other people, a clinician needs to develop special writing skills for clinical communication. In writing clinical reports, we convey information to others concerned about the child and want to get across to them not only what we learned from our testing, but what we inferred from our interactions with the child and the family. In acquiring skills as diagnosticians, then, we also are developing some new communication skills of our own.

BOX 2-5 Outline for a Clinical Report

- I. Identifying Information
 - Name:
 - Sex:
 - Address:
 - Date of birth:
 - Parents:
 - Date of evaluation:
 - Phone:
 - Age:
 - Referred by:
 - Examiner:
- II. Presenting Problem
- III. Historical Information
- IV. Examination Findings
 - Collateral areas
 - Norm-referenced language measures
 - Criterion-referenced measures
 - Behavioral observations
- V. Impressions
- VI. Summary
 - Examination findings
 - Severity statement
 - Prognosis
- VIII. Recommendations
 - Is intervention needed?
 - Goals
 - Suggestions for methods, approaches, activities, and reinforcers

STUDY GUIDE

- I. General Principles of Assessment for Suspected DLD
 - A. Discuss the aspects of an assessment that should be included in an assessment plan. What should not be included?
 - B. What goes into a case history? From where does the information come?

*hearing evaluation should also be made when expressive language skills (including phonology) are not age appropriate

FIGURE 2-16 A decision tree for assessment of DLD. (Adapted from Bishop, D.V.M. [2002]. *Speech and language difficulties*. In M. Rutter and E. Taylor [Eds.], *Child and Adolescent Psychiatry* [4th ed.] [pp. 664-679]. Oxford: Blackwell Publishing.)

- C. In what ways is the assessment process like hypothesis testing?
- II. Making an Assessment Plan
 - A. What does “screening” mean in a speech-language assessment?
 - B. Why do we need to establish baseline function as part of an assessment for a communication disorder?
 - C. How do clinicians choose intervention targets?
 - D. Give two reasons for doing ongoing assessment as part of an intervention program.
 - E. Give the rationale for doing a hearing assessment and a speech-motor assessment for every child suspected of communication disorder.
 - F. What is the role of the speech-language clinician in assessing intelligence?
 - G. How can the child’s social environment be assessed?
 - H. Discuss the areas of communication included in a language assessment.
 - I. Discuss some of the difficulties of assessing language comprehension.
 - J. Discuss the advantages and disadvantages of using speech sampling as an assessment of productive language.
 - K. Describe the qualities a clinician should look for in a good standardized test.
 - L. Define and give examples of measures of central tendency on standardized tests. Do the same for measures of variability.
 - M. Discuss the differences between standard and equivalent scores. What are the uses of each?
 - N. Define the standard error of measurement, and tell why it is important.
 - O. Discuss the difference between developmental scales and criterion-referenced measures. When would each be used?
 - P. Explain how standardized testing and other assessments provide complementary information in the assessment process.
 - Q. Explain why behavioral observations are included in an assessment.
 - R. Define and discuss *dynamic* and *functional* assessment. What is the purpose of each?
 - S. What is the difference between *formative* and *summative* assessment? What do we need to do both?
- III. Integrating and Interpreting Assessment Data
 - A. State the seven major sections of a clinical report, and describe what would be placed in each.
 - B. Give the three components of the recommendations section of a clinical report.
 - C. Discuss desirable traits of clinical report writing.

2-1

Name : _____

First	Middle	Last
Birthdate : _____		
Age _____ years _____ months _____		
Parents' names : _____		
Address: _____		
_____ Street		
_____ City	_____ State	_____ Zip Code
Phone: _____		
Date : _____		
Name of person completing this form _____		

Relationship to Child _____
Please answer the following items as completely as you can.

Who recommended you to this clinic?
Name _____ Phone _____
Address _____ Agency _____

A. School

Name	Phone
Address	Teacher-Grade

B. Briefly indicate how well your child functions in school _____

Indicate the physician who is best acquainted with the client.

Name	Phone
Address	

Indicate the physician who has treated the client most recently.

Name	Phone
Address	
Is there a physical handicap such as : Cleft palate _____	
Paralysis _____	Mouth or teeth deformity _____
Hearing loss _____	Other _____

Comments

Has there been a psychological evaluation?

When?	Where?

Is medical treatment being received at the present time?

If so, indicate for what condition treatment is being received.

IV. SPEECH AND LANGUAGE INFORMATION

A. Description

1. Speech

Is Child's speech understandable?

Are sounds omitted?

Is one sound substituted for another?

Is the voice unpleasant or different?

Explain _____

2. Rhythm

Is there stuttering? Stammering?

Rapid speech? _____

Other comments

3. Language

Does the Child understand more than he or she can say?

Is the language delayed?	Immature?

Absent? Lost?

Are sentences too short?

Incomplete? Vocabulary too small?

Does the child consistently use specific sounds to designate certain objects, people, or things?

4. History

Is the child aware of his or her speech problem?

Does it bother him or her?

Has the child had speech training?

Where, by whom, and how long?

Is more than one language spoken in the home?

Have others outside the family commented regarding the problem?

Please explain

V. HEARING INFORMATION

A. Is there a mild hearing problem?

Moderate? Severe?

B. Has there been preschool intervention?

Number of years? Where?

C. Describe time spent in other training programs for the hearing impaired _____

D. Describe medical assistance for hearing problem, including dates of surgery, etc. _____

E. Is a hearing aid worn? _____ Type _____
Where purchased? _____

Is the aid satisfactory? _____ Left ear _____
Right ear _____ Both ears _____

VI. RELEASE OF INFORMATION

Information that may help us plan a treatment program may be needed from physicians, schools, and other agencies who have assisted in your child's care. Please sign the following release so that we can obtain this information.

REQUEST FOR RELEASE OF CONFIDENTIAL INFORMATION

I hereby authorize you and/or your agency to release any and all information that is available on _____

First _____ Middle _____ Last _____

Birth date _____

Month _____ Day _____ Year _____

which may be requested by the staff of the Speech and Hearing Clinic. Additionally, I offer my permission for this "release of information" form to be duplicated and used at the discretion of the administrator of the clinic. I understand this information will be kept confidential and will be used by professional personnel for the sole purpose of diagnosis and treatment.

Sample Referral Letter

February 17, 2011

Donald McCormack, MS, School Psychologist
Albany Public Schools
Albany, NY

Re: JAMES, Christina
DOB: 11-20-2004

Dear Mr. McCormack,

Tina James is a 6-year-old girl being referred to you for a cognitive assessment, following my speech and language evaluation on January 23. Ms. James brought Tina to the diagnostic center on the recommendation of her first-grade teacher, Ms. Taylor. The primary concern was poor articulation and short, immature sentences. Ms. James reports that Tina has always been slow in her development.

The results of my speech and language assessment reveal adequate oral-motor function for speech. Tina makes many substitutions in producing speech sounds and often leaves off the final sounds in words. These processes combine to make her speech difficult to understand. Her comprehension of language is significantly below normal. Receptive vocabulary is at a 3-year level. Understanding of sentence structures is lower, at about a 30-month level. Her production of language is characterized by two- to-three word sentences and frequent omissions of inflectional endings.

As part of my evaluation, I did an informal assessment of cognitive skills, using developmental tasks such as copying figures and sorting. It is my impression that Tina's performance on these tasks is below age level. I have recommended that a cognitive assessment be performed to investigate these skills more formally. Because of Tina's problems with language, an assessment of nonlinguistic cognition would be most helpful. Please call me if there is any need to discuss this request further. Thank you for your help.

Yours,

Speech-Language Pathologist

Sample Clinical Report

I. Identifying Information

Name: Mark XXXXXX

Sex: Male

Address: 220 Mercer St., NYC

Date of Birth: 11/21/05

Parents: Carol and Jay XXXXXX

Date of Evaluation: 3/3/12

Phone: 673-3788

Age: 6;4

Referred by: Ms. Naughton, kindergarten teacher

Name of Examiner: Ellen Witherson

II. Presenting Problem

Mark's teacher told his parents at the parent-teacher conference that Mark is very hard to understand. When he talks, few of the children know what he means. Ms. Naughton, too, has great difficulty in understanding Mark's speech. The parents were aware that Mark had trouble making himself understood because they sometimes had difficulty understanding him themselves. Mark also seems to be unhappy about going to school and frequently complains that he is too sick to go.

III. Historical Information

Mark was the product of an unremarkable full-term pregnancy. He weighed 7 pounds 10 ounces at birth and had no newborn difficulties that the parents recall. Mark achieved motor milestones at the normal times, sitting up at 6 months, walking at 14 months, and feeding himself at 1 year. Parents report that speech was late to begin, with few words at 2 and no word combinations until 3. Mark's speech has

always been hard to understand, even for members of the family, although by now they can usually figure out what he means. Mother reports that Mark had two or three ear infections before the age of 2, but none after that age. No feeding problems were noted by parents. Medical history is unremarkable. Mark had regular checkups and received all immunizations on schedule.

IV. Examination Findings

Collateral areas: Hearing threshold testing revealed normal hearing in both ears. Examination of the oral mechanism revealed no gross structural abnormalities, but Mark had difficulty producing rapid, smooth repetitions of syllables such as /pə/, /tə/, and /kə/. This difficulty was even more pronounced in utterances with more than one consonant, such as /pətə/. Cognitive skills were assessed informally with sorting and drawing tasks. Mark appeared to perform at age level on these tasks.

Mark achieved the following standardized test scores:

Area Assessed	Test Used	Score	Normal Range
Articulation (pronunciation)	Goldman-Fristoe Test of Articulation	5th percentile	Above 10th percentile
Naming	Expressive Vocabulary Test	60th percentile	Above 10th percentile
Producing sentences	Structured Photographic Expressive Language Test	3rd percentile	Above 10th percentile
Understanding words and sentences	Test of Auditory Comprehension of Language—Revised	40th percentile	Above 10th percentile

Nonstandardized assessments of Mark's speech and expressive language skills included an analysis of spontaneous speech and several tasks designed to elicit the production of questions and grammatical morphemes. These analyses revealed that Mark makes numerous changes in his production of speech sounds that are similar to those used by younger children with normal speech patterns. These include leaving off final sounds in words (/da/ for "dog"), making all the sounds in a word more alike (/dadi/ for "doggy"), and substituting earlier-developing sounds for more difficult ones (/top/ for "soap"). When all these changes are put together in connected speech, the speech becomes difficult to understand. Mark's average sentence length in spontaneous speech was shorter than would be expected for his age. He used fewer helping verbs and other forms of sentence elaboration than would normally be seen in a 6-year-old. The ideas he expressed were age appropriate, however, in that he talked about past and future events, talked about imaginary topics, and was able to exhibit role-playing. His conversational abilities appeared age appropriate. He attempted to respond to requests for clarification when his speech was not understood, maintained topics for several turns, and changed his speech style when playing a baby and a daddy in the pretend situation.

In the question elicitation task, Mark was unable to change the order of words in a sentence to form a question. In a grammatical morpheme task, Mark consistently left off most morphemes, including ones that are generally easy to pronounce, such as "-ing."

V. Impressions

Mark worked hard during the assessment and seemed to be trying to do his best. During the expressive test, he was often unable to remember the whole sentence and could only repeat a few words of it. He became frustrated during the free-play session when the examiner was unable to understand him and turned to his mother to provide a "translation."

The parents seem very concerned about Mark's difficulty, but at the same time, they see many positive aspects of his growth. They point out that he is talking more than ever now, that they and his brother can understand him most of the time, and that he tries to imitate them when they correct his speech. They also are pleased that he is very interested in letters and numbers and likes to look at picture books and point out letters he recognizes. They feel he is a bright, capable little boy and think that with some time to mature he will outgrow his speech problems.

VI. Summary

Mark is an apparently bright 6-year-old boy with no significant medical history, but a history of delayed expressive language development. Current assessment reveals normal hearing and language comprehension. His ability to express meanings and engage in conversation appear age appropriate. Mark shows moderate to severe deficits in phonological development and a moderate deficit in expressive language, particularly in the areas of syntax and morphology. His ability to engage with others, his motivation to succeed, and the active support of his family suggest that progress in an intervention program should be significant. Given intensive intervention in phonology and expressive language over the next year, Mark's prognosis for significant improvement in intelligibility and for significant increases in sentence length and complexity is very favorable.

VII. Recommendations

Mark could benefit from speech-language intervention. Individual instruction for working on phonological targets could be combined with group instruction or in-class work with the teacher in consultation with the SLP to improve intelligibility in conversation and increase the complexity of expressive language.

The following specific goals are recommended:

1. Decrease omission of final consonants.
2. Increase production of age-appropriate consonant sounds.
3. Increase self-monitoring of intelligibility in connected speech.
4. Increase use of helping verbs, such as "can," "will," and "be" in sentences.
5. Increase use of grammatical morphemes, at first those that are easy to pronounce, such as "-ing."

Mark enjoys pretend play, and this setting may be useful for working on self-monitoring intelligibility. The parents are very committed to helping him and could be engaged in some home-work activities to carry over what is being worked on in the intervention program.

Principles of Intervention

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Discuss the various purposes of intervention.
2. List ways in which intervention can change communicative behavior.
3. Discuss way of identifying appropriate goals for communication intervention.
4. Describe interventions at various points on the continuum of naturalness.
5. List and discuss various contexts for providing intervention.
6. Describe methods of evaluating treatment outcomes.
7. Discuss principles of evidence-based practice.

The result of a successful language intervention program is not simply that a child responds correctly to more items on a test or accurately imitates the language stimuli given by the clinician. Successful intervention results in the child's being able use the forms and functions targeted in the intervention to effect real communication. The goal of our intervention, then, is not only to teach language behaviors but also to make the child a better communicator. To be ethical (American Speech-Language and Hearing Association, 2010) we also must be able to show that intervention has led to changes in language behavior that would not occur if no intervention were provided. Achieving all these goals is quite a challenge, one that requires us to be more than merely technicians. Effective language intervention involves a great deal of thought and a wide range of decision making, and many factors go into the process of choosing what, how, and where we will attempt to improve the client's communication. Let's examine these factors in some detail.

THE PURPOSE OF INTERVENTION

The first question we have to ask is, overall, what is the purpose of the intervention we are proposing? Olswang and Bain (1991) discussed three major purposes of intervention. The first is to *change or eliminate the underlying problem*, rendering the child a normal language learner, one who will not need any further intervention. Of course, all of us would like to achieve this with all our clients. Unfortunately, it is not usually possible. Frequently we do not even know what the underlying deficit is, let alone how to alleviate it. In a few instances, though, this might be a realistic goal. For a child with a hearing impairment, for example, if the loss is discovered during early childhood and

amplification or cochlear implantation can be used to achieve normal or nearly normal hearing, the language pathologist might need only to provide the child with help in getting language skills to approximate the child's developmental level (Geers, 2004; Niparko et al., 2010). Once these developmentally appropriate skills are achieved, normal acquisition could proceed, ideally anyway, without further intervention. Similarly, a young child who suffered a brain injury and developed an acquired aphasia might require intervention to restore language function, but a combination of intervention and the brain's normal plasticity can sometimes result in language learning's proceeding more or less normally, without need for further intervention after a period of time (Hanten et al., 2009).

In the real world of language intervention, though, cases in which the underlying cause of the impairment is both known and fully remediable are the exception. Most children present with language disorders of unknown origin or associated with incurable conditions, such as intellectual disabilities or autism. In these more common cases, we must settle for something less than changing the child into a normal language learner. Olswang and Bain (1991) identified this second choice as *changing the disorder*. In this case we attempt to improve the child's discrete aspects of language function by teaching specific behaviors. We teach the child, for instance, to expand the number of words and grammatical morphemes in sentences, to produce a broader range of semantic relations, or to use language more flexibly and appropriately. This makes the child a better communicator but does not guarantee that he or she will not need further help at a later time. This purpose is the one most commonly invoked when working with children who have developmental language disorders (DLD).

A third option identified by Olswang and Bain is to teach *compensatory strategies*, not specific language behaviors. Rather than, for example, teaching a child with a word-finding problem to produce specific vocabulary items on command, we would attempt to teach the child how to use strategies to aid recall of vocabulary during conversational tasks. We might teach the child to use phonetic features of the target word, as a cue, or to try to think of words that rhyme with the word that the child can't recall. This approach usually requires a good deal of cognitive maturity and is generally used to help older school-aged and adolescent students who have received language intervention for a number of years and will probably always retain some deficits (Wallach, 2005). Rather than trying to make their language normal, the clinician attempts to give them tools to function better with the deficits they have.

There is a fourth option. The goal of language intervention may be focused not on the child at all, but on the child's environment. In some situations it makes sense to try to influence the context in which a child must function instead, or in addition to trying to change the individual. Take Justin, for example.

Justin was born with severe cerebral palsy. After years of intervention he was still not able to produce much intelligible speech. In middle school, his language comprehension and literacy skills were near age level, though. He had been given an augmentative communication device that could speak what he typed out with a headstick. But his parents commonly forgot to bring the device along when they went out, and often forgot to send it to school with him, so he was forced to revert to vocal attempts to communicate, which were usually not very successful. Without an easy way to communicate with him, his classmates usually left him alone with his aide, so he had few peer interactions. His teacher interacted mostly with the aide, rather than Justin, giving her assignments to have Justin complete. His parents requested additional therapy for the oral language since they felt he was trying so hard to communicate that way. Instead, his clinician helped the family obtain a speech-generating program that worked on a smartphone. She also helped Justin devise a signal to use as a request for the phone, in order to remind his parents to send it to school with him. In addition, the clinician showed Justin's classmates how to use the program, so that they could talk to Justin by using it, as well as allowing him to talk to them. The classmates thought that being able to bring his phone to class was pretty cool and started spending more time interacting with Justin. The clinician encouraged the teacher, too, to use the device to give Justin his assignments directly, rather than talking to the aide. Now Justin can usually get someone to talk with him when he wants to say something. He also spends more time interacting with peers and participating, through his device, in class discussions.

Often this fourth option is combined with one of the other three to maximize the child's communicative potential. On occasion, though, modifying the environment alone will be the purpose of the clinician's activities.

Choosing which of these options to pursue as an overarching purpose is an important first step in an intervention plan. This choice enables the clinician to talk realistically with the family about the long-term goals and prognosis for the client. If alleviating the basic deficit is the purpose, the clinician can tell the family how long it will take for this to happen and how much intervention should be needed to achieve it. Since the long-term purpose is normal acquisition, only the short-term goals for intervention need to be specified. If modifying the disorder is the goal, both short- and long-term objectives need to be identified. If teaching compensatory strategies is the purpose of the intervention, then short- and long-term goals are formulated very differently than they would be for modifying language behavior itself.

Identification of the basic purpose of the intervention is based on the age and intervention history of the client, the nature of the disorder, and the way the environment interacts with the child's communicative function, as well as on the data collected from the communication appraisal. Young children with treatable or transient conditions may be restored to normal language learning with limited intervention. Older children with long histories of intervention who are likely to have lifelong deficits may benefit most from a compensatory-strategies approach. Modifying the environment may be the primary purpose for some clients and a secondary purpose

with others. Most commonly, though, the purpose of intervention is to modify the language disorder. Given this purpose, how is the change accomplished?

HOW CAN INTERVENTION CHANGE LANGUAGE BEHAVIOR?

According to Olswang and Bain (1991), when the purpose of intervention is to modify the disorder, language behavior can be changed in several ways. These alternatives are depicted in Figure 3-1.

Facilitation

The first role intervention can play is that of *facilitation*. With facilitation, the rate of growth or learning is accelerated, but the final outcome is not changed. In other words, facilitative language intervention helps children to achieve language milestones sooner than they would have if left to their own devices, but it does not mean that they ultimately achieve higher levels of language function than they would have without intervention.

If all facilitation does is increase the rate of acquisition of a particular behavior without altering the child's eventual language status, why bother to intervene? Gottlieb (1976) argued that facilitation could help a child increase his or her ability to differentiate among perceptions. In other words, facilitation can bring language to a higher level of awareness. This awareness can influence other aspects of development. For example, perhaps a child with a phonological disorder would outgrow his multiple articulation errors without intervention by age 8 or 9.

FIGURE 3-1 Purposes of intervention. (Reprinted with permission from Gottlieb, G. [1976]. Roles of early experience in species-specific perceptual development. In R. Aslin, J. Alberts, and M. Peterson [Eds.], *Development of Perception*. Vol. I. Orlando, FL: Academic Press.)

But if intervention to overcome these errors is provided earlier, this intervention may not only improve articulation but also may focus the child's attention on the sound structure of words. This increased awareness may contribute to the child's phonological analysis skills, which, as we shall see later, are important for the development of literacy. Some writers (e.g., Whitehurst et al., 1991) suggest that if therapy is merely facilitative and the child would eventually outgrow the disorder anyway, there is no justification for intervening. But many clinicians (Olswang & Bain, 1991; Paul, 1991a; Robertson & Weismer, 1999) have argued that facilitative intervention is justified because of the other systems in development that accelerating language skills may affect. Take a child like Sammy.

Sammy is a cute, apparently bright 3-year-old who has trouble communicating. His speech is hard to understand, his sentences are limited to two or three words, and he tends to push first and talk later. An appraisal by the local education agency (LEA) revealed that his problems were pretty much limited to expressive language; his cognitive and receptive language skills were at age level. He was having some difficulty with social skills and was showing some behavior problems, though, and seemed to be very frustrated about not getting his ideas across. His parents were quite anxious and concerned, particularly about his difficulties in getting along with other children. The LEA reported that he did not qualify for intervention because his deficits were limited to expression and were in the mild-to-moderate range. His parents were told that he would probably outgrow these deficiencies by the time he got to school. But they didn't want to wait. They were able to arrange for him to see a clinician through a private charitable agency. After 6 months his intelligibility, although still not normal for a child nearly 4 years old, had improved so that at least half of his utterances were comprehensible to peers. Sammy seemed a happier little boy; his aggressive behavior had decreased, neighbors were inviting him over to play more often, and his parents were feeling much more at ease.

This example illustrates how improving communication can affect a child's social skills, behavioral repertoire, self-esteem, and family relations. These outcomes also are considerations in deciding whether to initiate intervention. Communication influences many aspects of a child's life, and increasing its maturity, even if a problem would eventually be outgrown, can often result in changes that go beyond the language behavior itself.

Maintenance

A second way that intervention can change behavior is through *maintenance*. Olswang and Bain (1991) explained that intervention for the purpose of maintenance preserves a behavior that would otherwise decrease or disappear. Gottlieb (1976) argued that maintaining behaviors is important to "keep an immature system intact, going, and functional so that it is able to reach its full development at a later stage" (p. 28). A toddler with a cleft palate, for example, for whom surgery was delayed for medical reasons, might need intervention to maintain babbling and early

vocal behaviors. These behaviors would then be functioning and available for building intelligible language once the palatal vault was closed by surgery.

Induction

Finally, intervention can serve the role of induction. *Induction* of a behavior means that the intervention completely determines whether some endpoint will be reached. Without the intervention, the outcome is not achieved. For example, a hearing-impaired 4-year-old who uses very little spoken language, who comes from a hearing family, and who has no access to the deaf community will not learn Sign language as a form of communication unless intervention takes place. The use of intervention to teach the child Sign language as a form of communication would be an example of induction.

Induction is the most dramatic form of intervention and the one for which we would most like to take credit. Unfortunately, in most real-life situations we do not know ahead of time whether our intervention is accomplishing facilitation or induction. Induction, of course, is the most cost-effective purpose of intervention, and when deciding whether to intervene, we feel more at ease if we can convince ourselves that the effect of the intervention will be induction rather than facilitation. In truth, though, we often do not have enough information to know. In these cases, we would argue that clinicians be familiar with the role of the facilitation in language learning and be prepared to assert the importance of facilitation as a valid outcome of intervention.

DEVELOPING INTERVENTION PLANS

Once a decision to establish an overall purpose for intervention has been made and we specify, or at least think about, how we expect our intervention to change client behavior, the next step is to develop a specific plan. Like assessment, intervention should be carefully considered and planned in detail before it is implemented. One aspect of this planning involves making use of the available scientific evidence in choosing our intervention methods. This aspect of planning is referred to as using *evidence-based practice*. Let's talk about some of the ways we as clinicians can use evidence to decide on what constitutes our best practice for our clients.

Evidence-Based Practice

Let's imagine you are a clinician working with a preverbal 3-year-old named Brendan. One day, Brendan's parents come to you with a newspaper article, which says that exposing children who don't talk to a certain kind of auditory stimulation (through a special set of earphones) leads to speech. There's a Web address in the article, and the parents have looked it up; the program is available for \$2000; all they have to do is send for it and have the child wear the earphones for 20 minutes three times a day. They ask you whether you think they should purchase the program, and whether you would include 20 minutes of this treatment within each of Brendan's sessions with you. How will you answer them? These kinds of questions lead us to the need for evidence-based practice (EBP).

Ochsner (2003) defined evidence-based practice as "the conscientious, explicit, and unbiased use of current best research results in making decisions about the care of individual clients" by integrating clinical expertise with the best available external clinical

evidence from systematic research (Sackett et al., 2000). Dollaghan (2007) discussed these issues and reminded us that EBP does not *only* mean solving clinical problems by going to the external evidence, defined primarily as published literature, to find the best available scientific support for the use of specific intervention approaches, although it does mean that, too. Fey and Justice (2007) tell us that EBP includes evaluating internal evidence as well. Internal evidence comes from characteristics of the client and family, their willingness to participate in a treatment approach, and their preference; as well as our own clinician preferences, professional competencies, and values; and the values, policies, and culture of the institutions in which we work. Let's talk about how we can evaluate external evidence first, then we'll consider how internal evidence is included in this decision-making process.

Dollaghan (2004, 2007) suggested we approach external evidence using three principles:

1. The opinions of expert authorities (including expert panels and consensus groups) should be viewed with skepticism.
2. All research is not created equal. Everything that gets published is not necessarily true (or to paraphrase your grandmother, you can't believe everything you read). Some studies are better, and therefore better suited to inform clinical decisions, than others.
3. Clinicians must be critical about the quality of evidence they use to guide clinical decision-making.

Let's see what these principles might mean to us in practice. First, they tell us that we can't take "experts" at their word. If you go to a workshop and a famous clinician tells you about a new approach that can't fail, you have to ask yourself, "How does she know?" If the answer is not based on data presented, but rather on her confidence and experience, we have to consider her endorsement with a few grains of salt. Why? Well, maybe the approach does work for her, but it works because she is an especially talented clinician and another person doing the same thing may not get the same results. Or maybe she works with certain kinds of clients, who are not like the clients in your practice. There could be lots of reasons. The point is, her saying it works is not enough. If you decide to try the approach, you should carefully monitor its effects on your clients, and perhaps compare it to other approaches you are using before deciding that it is really right for your practice and your clients.

Dollaghan's second and third principles tell us that not only must we view experts with skepticism, we must read published research with the same critical attitude. When we say "critical" in this context, though, we don't just mean finding fault. We have a very specific set of criteria in mind that we want to measure the studies we read against. Fey and Justice (2007) outlined a series of questions we can ask ourselves to help determine the type and quality of a study. These are summarized in Figure 3-2. The answers to these questions allow us to classify a report we read in the literature according to the levels of evidence it provides. These levels are summarized in Table 3-1. The higher the level of evidence we can find for a particular approach, the more confident we can be that the approach has strong scientific support. Finn, Bothe, and Bramlett (2005) provide additional guidance for evaluating claims about evidence.

But suppose we find strong scientific support for a particular practice. Is that the end of our decision-making process? Perhaps, but perhaps not. I'll give you an example. As we'll see in Chapter 4, some of the strongest support available for any approach to eliciting initial speech from young children with autism spectrum disorders (ASD) is for behavioral, or operant, methods. These methods have

been carefully investigated for many years, and have the greatest number of studies as well as the highest quality of research evidence behind them. Does this strong scientific evidence mean to us that every preverbal child with ASD must be given operant training? You've probably already thought of some reasons why the answer is "not necessarily." Perhaps the clinician is not well trained or experienced in this approach, or perhaps it conflicts with her values. Maybe the parents don't like it, and think it would make their child too passive. All these are examples of the internal evidence that also needs to go into deciding about an approach to intervention.

What does EPB require of us, then? Do we have to read every published study in order to be EBP practitioners? Of course not—that would be impossible! Should we disregard scientific evidence if our own or a family's values or experiences don't match it? That would not be very responsible, either, since research does provide guidance in making clinical decisions. Fey and Justice (2007), Dollaghan (2007), and Sackett et al. (2000) outlined a reasonable approach to incorporating EBP that includes the following steps:

1. Formulate your clinical question, including the four "PICO" elements:
P—Patient or Problem
I—Intervention being considered
C—Comparison treatment (such as the prevailing approach or no treatment)
O—desired Outcome

Example: Would Brendan, a 3-year-old with ASD and no speech (P) show greater improvement with an intervention that targets speech through an operant approach (I), or one that uses an alternative modality, such as a Picture Exchange Communication System (PECS; Bondy & Frost, 1998) as shown by increases in verbal communicative acts (O)?

2. Use internal evidence (such as clinical experience and family preferences) to determine what your typical, "first stab" approach would be.

Example: Brendan's parents saw a newspaper article about PECS use in a nearby town. The child in the paper started saying a few words after working with PECS for several months. The parents think it makes sense and want to try it. You attended a PECS workshop several months ago, have used it with a few clients, and feel more confident using this technique than an operant approach with which you have little experience. You would opt for trying PECS first, other things being equal.

3. Find the external research evidence base. Use the American Speech-Language and Hearing Association (ASHA) database (www.asha.org) or other databases (such as MEDLINE or PsychInfo) available from libraries to search for information on your question. Start by reading the most recent review articles to find out what has been written lately; read abstracts of papers to decide if reading the whole paper will be worth your time. Choose just a few articles that come closest to answering your question to read in their entirety. If you have to choose just one or two, choose the most recent, since these will review earlier papers on the topic.
4. Grade the studies for (a) relevance to the clinical question, (b) the level of evidence provided by the study based on its design and quality, and (c) the direction, strength, and consistency of the observed outcomes, using the criteria in Table 3-1 and Figure 3-2.

FIGURE 3-2 Flowchart for evaluation of published reports. (Adapted from Fey, M., and Justice, L. [2007]. Evidence-based decision making in communication intervention. In R. Paul and P. Casella [Eds.]. *Introduction to clinical methods in communication disorders*. Baltimore: Paul H. Brookes.)

5. Integrate internal and external evidence.

Example: After reading several reviews and recent papers on behaviorist approaches, you are impressed with their high level of scientific support. You have read a few studies supporting PECS, but their quality is not very high. Still, the internal evidence for PECS seems strong, and Brendan has started doing more vocalizing, so he may be ready to use speech, once he learns some communication skills through PECS.

6. Evaluate the decision by documenting outcomes.

Example: You take a baseline sample of play between Brendan and his mother for communicative acts using verbal and nonverbal means before starting PECS. Brendan is

producing fewer than one communicative act/minute; most are vocal but not verbal. After 6 weeks of PECS, you take another sample of communication; Brendan now produces two acts/minute spontaneously, using both PECS and vocal behavior. He produces a one word approximation, with prompting from Mom: /mə/, for *more*, using it three times to request repetition of a tickle game. You conclude that PECS is doing its job, and decide to continue with the program, but to re-evaluate in another 6 weeks to be sure verbal communication continues to emerge. If it does not, you will consider a more direct speech approach, perhaps using more operant methods, at that time.

TABLE 3-1 Levels of Evidence

Level	Type(s) of Evidence
Ia	A systematic meta-analysis of multiple well-designed randomized controlled studies.
Ib	A well-conducted single randomized controlled trial (RCT) with a narrow confidence interval
IIa	A systematic review of nonrandomized quasi-experimental trials or a systematic review of single subject experiments that documents consistent study outcomes.
IIb	A high quality quasi-experimental trial or a lower quality RCT or a single subject experiment with consistent outcomes across replications.
III	Observational studies with control (retrospective studies, interrupted time-series studies, case-control studies, cohort studies with controls)
IV	Observational studies without controls
V	Expert opinions without critical appraisal or theoretical background or basic research

(Adapted from Fey, M., and Justice, L. [2007]. Evidence-based decision making in communication intervention. In R. Paul and P. Casella [Eds.]. *Introduction to clinical methods in communication disorders*. Baltimore: Paul H. Brookes.)

As you can see from this brief introduction to EBP, it offers a framework to help us make the crucial clinical decisions that go into the planning of an intervention program. Brackenbury, Burroughs, & Hewitt (2008) provide additional guidelines for using EBP in clinical practice. Let's look at some of the other elements that go into this planning process.

Products of Intervention: Setting Goals

McCauley and Fey (2006) and McLean (1989) suggested that there are three aspects of the intervention plan: the intended *products*, or objectives, of the intervention; the *processes* used to achieve these objectives; and the *contexts*, or environments, in which the intervention takes place. Let's see what each of these aspects entails.

A major source of information for goal setting is the assessment data. The appraisal tells us about the child's current level of functioning in the various language areas. McCauley and Fey (2006) describe intervention goals at three levels. These include the following:

Basic goals: Identify areas selected because of their importance for functionality or because of the severity of the deficit; these are general goals and usually correspond to long-term objectives in an educational plan (e.g., new grammatical forms).

Intermediate goals: Provide greater specification within a basic goal; usually there are several levels of intermediate goals associated with each basic goal (e.g., auxiliaries, articles, pronouns).

Specific goals: Specific instances of the language form, content, or use identified as intermediate goals. These are considered steps along the way to the broader and more functional basic goals, and should be based on the child's functional readiness, those which the child uses correctly on occasion or for which the child produces obligatory contexts without producing the target form (e.g., *is, are; a, the, he, she*).

Because many children with DLD have multiple linguistic deficits, it is helpful to have some criteria for setting priorities among the deficits identified in the baseline assessment. Nelson, Camarata, Welsh, Butkovsky, and Camarata (1996) found that both forms that did not appear in the child's speech at all and forms that were used

correctly some of the time were equally amenable to improvement with intervention. This research suggests that both these types of forms make suitable intervention targets. Fey (1986) and Fey, Long, and Finestack (2003) suggested, though, that forms that the child is already using a majority of the time correctly, even if some errors are still being made, should *not* be targeted for intervention. These forms are well on their way to mastery and will probably improve without direct teaching. Their suggestions are summarized in Box 3-1.

This strategy for goal setting can be thought of as targeting the child's *zone of proximal development* (Levykh, 2008; Schneider & Watkins, 1996; Shepard, 2005; Vygotsky, 1978). The zone of proximal development (ZPD) is the distance between a child's current level of independent functioning and potential level of performance. In other words, the ZPD defines what the child is ready to learn with some help from a competent adult. Figure 3-3 gives a schematic representation of the ZPD. Choosing a goal within the child's current knowledge base is wasting the child's time, teaching something that is already known. Unfortunately, this error is sometimes made in intervention out of a misguided desire to ensure that the child succeeds on an intervention task. If a goal, such as production of a plural morpheme, is identified, and a child is found to perform at 80% correct on the first activity involving this morpheme, this indicates that the child does not need to be taught it. To persist in providing intervention on such an objective is to work short of the child's ZPD. The client is not being challenged to assimilate new knowledge and is simply demonstrating what he or she has already learned. This may make the clinician feel good, but it does not help the child acquire new forms and functions of language.

If the child is only 40% correct in the first sessions on a certain morpheme, however, the clinician can feel relatively confident that the form is within the child's ZPD. If continued intervention eventually produces 80% correct responses, the clinician would be justified in continuing to provide opportunities for the child to use this form, to stabilize and generalize its use. After several sessions in which the form is used correctly almost all the time in both structured and conversational contexts, though, the notion of ZPD suggests that it is best to move on to another target, checking back on plural morphemes occasionally to be sure that they are maintained in the child's repertoire. Focusing on targets for longer than necessary to get them stabilized into the child's knowledge base

BOX 3-1 Suggestion for Setting Priorities among Intervention Goals

HIGHEST PRIORITY

Forms and functions clients uses in 10% to 50% of required contexts

HIGH PRIORITY

Forms and functions used in 1% to 10% of required contexts, but understood in receptive task formats

LOWER PRIORITY

Forms and functions used in 50% to 90% of required contexts.

Forms the client does not use at all and does not demonstrate understanding of in receptive task formats.

Adapted from Fey, M. (1986), *Language intervention with young children*. San Diego, CA: College-Hill press; Fey, M. Long, S. And Finestack, L.(2003). Ten principles of grammar facilitation for children with specific language impairments. *American Journal of Speech Language Pathology*, 12, 3-15.

FIGURE 3-3 Zone of proximal development (ZPD).

and generalized into conversational use does not make the most of intervention resources.

Similarly, it is important to choose objectives that are not beyond the client's ZPD. If a goal is too far above the current knowledge base, the child will be unable to acquire it efficiently and may not learn it at all. For a child in the two-word stage of language production, for example, using comparative “-er” forms, which are normally acquired at a developmental level of 5 to 7 years (Carrow-Woolfolk, 1999a), is in most circumstances too far from the child's current level of functioning to be an appropriate goal. Again, the probable range of the ZPD is based on detailed assessment data, which pinpoints where the child is already functioning, and on knowledge of normal development, which allows us to determine the next few pieces of language development to fall into place. Lidz and Gindis (2003) and Schneider and Watkins (1996) point out that using dynamic assessment techniques to establish the ZPD also is helpful. This would mean identifying a particular form that is used infrequently or not at all in the client's spontaneous speech. Diagnostic teaching could be used to determine whether adult scaffolding makes it possible for the child to produce the form more accurately or often. If so, the form is within the child's ZPD and makes an appropriate therapy target.

We will need to take some other considerations—besides the child's current level of functioning and the ZPD—into account when setting long- and short-term goals, though. Let's examine what some of these considerations might be.

Communicative Effectiveness

Fey (1986), Lahey (1988), and McCauley and Fey (2006) all emphasized the importance of choosing objectives not only on developmental grounds, but also on the grounds of how efficient

the targeted behaviors will be in increasing a child's ability to communicate. This suggests that when a variety of communicative problems emerges from assessment, it makes sense to choose skills that most readily accomplish social goals as highest-priority targets for intervention.

For example, suppose a 6-year-old is using primarily four- and five-word utterances. Let's say the child is producing all grammatical morphemes correctly, except appropriate forms of the verb “to be” and is expressing a range of age-appropriate meanings and communicative functions in simple, unelaborated sentences. What should be targeted first? Developmentally appropriate goals could include both forms of “to be” and elaborated sentence types such as passive sentences, sentences with embeddings, and conjoined sentence forms. But which might be most efficient for increasing communicative ability? Although the “be” forms might appear earlier developmentally than elaborated sentence types, use of “be” forms is usually redundant in context. In other words, no new meaning is added by saying, “They are going away,” instead of “They going away.” The former is correct by adult grammatical standards but not really much more efficient in terms of communication. So it may make sense to target sentence elaboration objectives as a higher priority. Passive sentences, although developmentally appropriate, would again not add much to the child's communicative repertoire, since the same ideas can usually be expressed in active form. Embedded sentences, such as relative clauses, might help the child encode more than one proposition within a sentence, making expression more compact, efficient, and sophisticated. Conjoined sentences also could be used to combine propositions within sentences. A decision as to which of these two forms to target first might be made by looking at what meanings the child is already attempting to combine in his discourse. If the child is producing sentence pairs that attempt to specify objects (“I like that gum. It has stripes.”), relative clauses could be targeted to allow the production of more sophisticated versions of what he's already saying (“I like the gum that has stripes.”). If temporal or causal meanings are being juxtaposed (“He went home. He got tired.”), conjoinings with appropriate conjunctions to specify these relations could be targeted (“He went home because he got tired.”).

Decisions about communicative effectiveness of language objectives are particularly important for children who are not likely ever to achieve adult communicative levels, such as those with severe autism or intellectual disability. For these children especially, goals that may come next in the developmental sequence but do not allow the child to function as a more effective communicator take lower priority. These decisions are also important for children who are producing a very limited range of meanings or communicative functions. For these clients, expanding the range of ideas and intentions that can be expressed may be more important than syntactic accuracy, even when syntactic goals would appear to be suggested by the developmental sequence. The key is to remember that the overarching goal of intervention is not only to improve language but also to improve communication. With this goal in mind, developmental considerations can be kept in perspective.

New Forms Express Old Functions; New Functions Are Expressed by Old Forms

This dictum, articulated by Slobin (1973), tells us that when choosing targets for intervention, we must be careful to require that the child do only one new thing at a time. In targeting a new form, such as color vocabulary, we need to ask the child to use this form to serve a communicative function that has already been expressed

FIGURE 3-4 The continuum of naturalness. (Adapted from Fey, M. [1986]. *Language intervention with young children*. San Diego, CA: College-Hill Press.)

Clinician-directed (CD) approaches, also referred to as drill (Shriberg & Kwiatkowski, 1982a) or discrete trial intervention (DTI), attempt to make the relevant linguistic stimuli highly salient, to reduce or eliminate irrelevant stimuli, to provide clear reinforcement to increase the frequency of desired language behaviors, and to control the clinical environment so that intervention is optimally efficient in changing language behavior. CD approaches tend to be less naturalistic than other approaches we will discuss, since they involve so much control on the part of the clinician and since they purposely eliminate many of the natural contexts and contingencies of the use of language for communication. Peterson (2004) defined these approaches as ones in which the clinician selects the stimulus items, divides the target language skill into a series of steps, presents each step in a series of massed trials until the client meets a criterion level of performance, and then provides an arbitrary reinforcement. Roth and Worthington (2010) provide an excellent introduction to this approach. Their summary of this basic training protocol appears in [Box 3-2](#).

An advantage of CD approaches is that they allow the clinician to maximize the opportunities for a child to produce a new form, producing a higher number of target responses per unit time than

other approaches allow. This provides excellent opportunities for the child to get extended practice using a new form or function.

Proponents of this approach (e.g., Connell, 1987; Fey & Proctor-Williams, 2000; Smith, Eikeseth, Sallows, & Graupner, 2009) also point out that its unnaturalness is itself an advantage. They argue that if clients were going to learn language the “natural” way, by listening and interacting with others, they would not need intervention. The fact that the child has, for whatever reason, failed to learn language through natural interactions suggests that something else is needed. The something else, in this view, is the highly structured, clinician-controlled, tangibly reinforced context of the behaviorist’s intervention.

There is something to be said for this position. CD approaches have been shown in a large literature of research studies to be consistently effective in eliciting a wide variety of new language forms from children with language disabilities of many types (see Abbeduto & Boudreau, 2004; Fey, 1986; Goldstein, 2002; Paul & Sutherland, 2005; Peterson, 2004; Reichow & Wolery, 2009; Rogers, 2006, for reviews). The proponents of the CD approach appear to be justified in arguing that children who have not learned language the “old-fashioned way,” by interacting naturally with their parents, benefit from formal behavior modification procedures. Furthermore, some research (Friedman & Friedman, 1980) suggests that, while children with higher IQs learn better in a more interactive intervention program, those with lower IQs or more severe disabilities perform better when a CD approach is used. Connell (1987) showed, using an invented morpheme, that children with normal language acquisition learned more efficiently when the form was merely modeled for them, whereas children with DLD learned the form better when they were required to imitate the instructor’s production of it. These studies tend to support the behaviorist position that CD approaches to language intervention work better than more naturalistic ones for children with DLD. Studies of children with ASD have also shown that CD approaches appear superior to more eclectic approaches for improving language and cognitive skills (e.g., Cohen, Amerine-Dickens, & Smith, 2006; Eikeseth, Smith, Jahr, & Eldevik, 2002; Eikeseth, Smith, Jahr, & Eldevik, 2007).

But, of course, that’s not the whole story. Cole and Dale (1986), for example, were not able to replicate the Friedman and Friedman results and found no differences between interactive and CD approaches. Nelson et al. (1996) showed more rapid acquisition of grammatical targets and increased generalization with a conversational intervention treatment than an imitative one. Camarata, Nelson, and Camarata (1994) reported that children with language impairments learned syntactic targets more quickly under naturalistic conditions than with a CD approach. A meta-analysis by Delprato (2001) suggested that naturalistic interventions showed a consistent advantage over CD methods. Howlin, Magiati, Charman, and MacLean (2009) found CD approaches worked well for some children but not others. More fundamentally, perhaps, numerous studies (e.g., Hughes & Carpenter, 1983; Mulac & Tomlinson, 1977; Zwitman & Sonderman, 1979; see Peterson, 2004, for review) show difficulties in generalization to natural contexts of forms taught with a CD approach, even when use reaches high levels of accuracy within the CD framework. Cirrin and Gillam (2008) report, in a review of literature, that imitation (CD), modeling (child-centered, CC), or modeling plus evoked production (hybrid) all are equally but modestly effective in teaching new syntactic and morphological forms. Gillam et al. (2003), while generally favoring more naturalistic approaches, argue that clinicians and

BOX 3-2 Training Protocol for Clinician-Directed Intervention

- Clinician gives instructions in declarative form (“Say the name for the picture after me.”).
- Clinician presents stimulus or antecedent event (“Big ball.”).
- Clinician waits for client to respond, allowing sufficient time for client to formulate response.
- Clinician presents consequent event or reinforcement (primary such as food, or secondary, such as social praise [“Good talking”], tokens to accumulate for a prize, or feedback regarding the acceptability of the response).
- Feedback might include biofeedback instrumentation or information on performance (“You said four of the five correctly.”)

Adapted from Roth, F. & Worthington, C. (2010). *Treatment resource manual for speech-language pathology* (4th ed.) Clifton Park, NY : Delmar.

Clinician-directed intervention provides a high level of structure.

researchers need to determine which developmental profiles in clients are best matched to particular intervention methods.

It seems, then, that while CD approaches can be highly efficient in getting children to produce new language forms, they are not so effective in getting them to incorporate these forms into real communication outside the structured clinic setting, and that more naturalistic methods can also provide an efficient means of addressing language targets. What shall we make of these findings? Some writers, including Hubbell (1981), Norris and Hoffman (1993), and Owens (2009), have argued that the lack of generalization seen in CD approaches renders them useless and that the only approaches that are right for language intervention are more natural and interactive. This view, in our opinion, involves “throwing the baby out with the bath water.” Since CD approaches have proven efficacy in eliciting new language forms, why not take advantage of this efficacy? CD approaches can be used in initial phases of treatment to elicit forms that the child is not using very much spontaneously or at all. Fey, Long, and Finestack (2003) argue that drill formats that emphasize contrasts between two forms (such as past/present or singular/plural) are the most effective use of CD formats. Either simultaneously, or later, once the form or function has been stabilized with a CD approach, some of the more naturalistic approaches we will discuss can be used to help bring the form into the child’s conversational repertoire (Smith, 2001). Let’s look at three major varieties of CD activities: drill, drill play, and modeling.

Drill

Shriberg and Kwiatkowski (1982a) defined several types of clinical activities in terms of their degree of structure. The most highly structured in their framework is drill, which makes use of the classic DTI format. In a drill activity, the clinician instructs the client concerning what response is expected and provides a training stimulus, such as a word or phrase to be repeated. These training stimuli are carefully planned and controlled by the clinician. Often they contain *prompts* or instructional stimuli that tell the child how to respond correctly, for example by imitating the clinician. If prompts are used, they are gradually eliminated or *faded* on a schedule predetermined by the clinician. When prompts are used, the client provides a response to the clinician’s stimulus. If this response is the one the clinician intended, the child is *reinforced* with verbal praise or some tangible reinforcer, such as food or a token. A *motivating event* also may be provided. For example, if the child is to label clothing items, he or she may be asked to place a sticker of the item in a sticker album after it has been named appropriately and the response has been reinforced. If the client’s response is not the intended target, the clinician attempts to *shape* the response by reinforcing the production of parts of the complete target and gradually increasing the number of components that must appear correctly to obtain the reinforcement. Drill is the most efficient intervention approach in that it provides the highest rate of stimulus presentations and client responses per unit time.

One problem with drill in Shriberg and Kwiatkowski’s study was that neither the clients nor the clinicians liked it very much. The clients did not find it very motivating, and the clinicians were uncomfortable with its high degree of structure and low level of motivation. It is interesting to note that the clinicians in the study did not like drill even though it was obvious that it got the job done and provided an efficient and effective form of intervention.

Drill Play

Drill play is another CD approach, which differs from drill only in that it attempts to provide some motivation into the drill structure. It does this by adding an *antecedent* motivating event, that is, one

that occurs not only after the target response is reinforced but also before it is even elicited. Thus there are two motivating events in drill play, one that goes along with the original training stimulus the (*antecedent* motivating event) and one that follows the reinforcement (the *subsequent* motivating event). For example, take the activity mentioned before—using stickers to motivate naming clothing items. As an antecedent motivating event, the client may be allowed to choose any sticker from a sheet of clothing stickers that he or she would like to put in the album. The training stimulus would elicit the name of clothing item represented by the sticker. After reinforcement for correct labeling, the client would be allowed to put the sticker in the album, as a subsequent motivating event.

Shriberg and Kwiatkowski (1982a) found drill and drill play to be equally efficient and effective in eliciting responses in phonological intervention. Furthermore, clinicians in the study liked drill play a lot better than they did drill and believed that their clients did, too. Do these findings about phonological intervention transfer to language? We don’t really know, since this question has not been addressed in language intervention research in as clear a manner as Shriberg and Kwiatkowski have addressed it. But it seems reasonable to expect the two modes of intervention to produce similar outcomes with semantic, syntactic, pragmatic, and phonological goals. These findings suggest that many of the advantages of highly structured CD approaches can be retained while client motivation and clinician comfort are increased, by small but well-thought-out modifications of the basic DTI approach.

Does this mean that we should never drill, if drill play is just as effective and more fun? Not necessarily. Some children, in fact, may enjoy the predictability and simplicity of drill. Many computer language-teaching programs are, in fact, drill formats that use their own graphic displays as subsequent motivating events, and many children find these to be quite a treat. The bottom line, in our opinion, is that if drill works for a certain client, we should by all means use it initially to elicit new forms and functions. If it doesn’t work, we should use whatever works better. The important thing is to have a range of techniques and approaches on our clinical palate from which to draw, mix, and match to suit the needs of clients.

Modeling

Fey (1986) presented a second CD alternative to straight drill procedures. This arises from social learning theory and involves the use of a third-person model—thus the name, *modeling* approach. Like drill, modeling uses a highly structured format, extrinsic reinforcement, and a formal interactive context. But here, instead of imitating, the child’s job is to listen. The client listens as the model provides numerous examples of the structure being taught. Through listening, the child is expected to induce and later produce the target structure. The child never has to imitate a structure immediately after the model. Instead this procedure implicitly requires the child to find a pattern in the model’s talk that is similar across all the stimuli presented. In Leonard’s (1975a) modeling procedure, a “confederate,” such as a parent, is used by the clinician as a model. The clinician, after pretesting the client on the target structure, gives the model a set of pictures not used in the pretest and asks, “What’s happening here?” The confederate provides, for example, a *be* + (*verb*) + *-ing* utterance that describes each picture presented by the clinician (e.g., “the boy is drinking,” “the girl is eating,” “the cat is walking”). After 10 or 20 of these descriptions, the client is asked to “talk like” the model and to describe a similar but not identical set of pictures. In this phase the model and client alternate their productions until the child produces three consecutive correct versions. Then, the child is asked to continue until a criterion (say,

8 out of 10 consecutive correct responses) is reached. At this point, the client would be tested on the pretest stimuli without models. This method can easily be adapted when a confederate is not available by using a doll or puppet (with the clinician's voice) as a model.

All three variations we've discussed—drill, drill play, and modeling—share the tightly structured, formal, clinician-controlled features that characterize operant approaches to intervention. They share the advantages these approaches provide: specification of linguistic stimuli, clear instructions and criteria for appropriate responses, reinforcement designed to increase the frequency of correct responding, high levels of efficiency in evoking maximal numbers of responses per unit time, and proven effectiveness in eliciting new language behaviors. They all share certain disadvantages, too. They are relatively “unnatural” and are dissimilar to the pragmatic contexts in which language is used in everyday conversation. Perhaps as a result, their targets are not spontaneously incorporated into everyday language use, even when they reach criterion levels in the structured intervention situation. These facts imply that CD approaches ought to be considered in initial phases of intervention to evoke use of forms the child is not using very often in spontaneous conversation, because of their great efficiency for this purpose. Because of their drawbacks, though, CD approaches should be combined with other modalities to effect the transition from use in formal intervention contexts to use in everyday interactions. Let's see what some of these alternative approaches might be.

Child-Centered Approaches

You can lead a horse to water, but you can't make it drink. That's the problem with CD approaches. Some children simply refuse to engage in CD activities, no matter how good it is for them. Some clinicians might call these children “behavior problems” and would spend long stretches of intervention time trying to train them to participate in CD formats. These “hard-to-treat” children rebuff any attempt to get them to say what the clinician tells them to say, no matter how tempting the reinforcement.

For these children, an alternative intervention approach seems warranted. That is, even if we believe that CD approaches are the most efficient means of language change, we may need to have another weapon at our command for children who refuse to engage in them, at least until we can establish a better relationship with the client and get him or her to want to cooperate with us. Sometimes we need to win a child's trust.

For another kind of client, too, the CD approach may not be the best first step. This is the child that Fey (1986) called “unassertive.” An unassertive child responds to speech, but rarely initiates communication. These children are passive communicators who let others control interactions. In a sense, a CD approach panders to these clients' propensity to sit back and let others do the interactive work. Having these clients respond when and how they are told to is essentially reinforcing them to continue the old, passive communication pattern.

For both these children—the obstinate child and the unassertive communicator—CD approaches may not be the most appropriate first step in an intervention program. That is not to say that CD approaches never work for these clients, only that we may need to do something else first before we ask them to work with us. For the obstinate and unassertive child particularly, the child-centered (CC) approach (Fey, 1986; Girolametto & Weitzman, 2006; Sheldon & Rush, 2001) may be a good introduction to intervention. CC approaches can be appropriate adjuncts to the program for many children with language disorders. CC approaches go by several names, including *indirect language stimulation* (ILS; Fey, 1986),

facilitative play (Hubbell, 1981), *pragmaticism* (Arwood, 1983), and *developmental* or *developmental/pragmatic approaches* (Prizant & Wetherby, 2005a). In using a CC approach, a clinician arranges an activity so that opportunities for the client to provide target responses occur as a natural part of play and interaction. From the child's point of view, the activity is “just” play or conversation. A clinician may use a variety of linguistic models as instructional language when they seem appropriate in the context of the child's activity. There are no tangible reinforcers, no requirements that the child provide a response to the clinician's language, and no prompts or shaping of incorrect responses when they do occur, although the clinician does *consequence*, or follow up, any child remarks in specific ways, as we'll see.

CC intervention puts the child in the driver's seat. Apart from choosing the materials with which the child will play, the clinician does not direct the activity. Rather, we follow the child's lead, doing what he or she is doing and talking about what he or she is talking about or doing. This has a great many advantages for both obstinate and unassertive clients. Rather than spending all their energy resisting, in the case of the obstinate child, or passively complying, as the unassertive one will do, clients engaged in a CC activity spend their time in natural, enjoyable play with a very accepting and responsive adult who makes a consistent and salient match between what they are doing and the language used to talk about it. And all clients can benefit from opportunities to see how actions and objects are mapped onto words in the context of fun, familiar activities.

When we use CC intervention, the first (and perhaps hardest) thing we must learn to do is *wait*. The key to this approach is to *respond* to the client. To do this, we have to wait for the client to do something. Ideally, that something will be to talk. If it is, we can respond to the child's language with one of several specific verbal techniques. Sometimes, though, we must interpret some action of the child's and act as if it were intended to communicate, even though the client may not truly have had such an intention. Once the child has said or done something that we can interpret as communicative, we then respond to the behavior in a way that models communicative language use. Unlike in the CD approach, we are not trying to elicit specific structures from the client. Instead, we react to the child's behavior, placing it in a communicative context and giving it a linguistic mapping.

Child-centered intervention.

The clinician does this mapping by using a variety of techniques that constitute the indirect language stimulation approach. These techniques can be summarized as follows:

1. *Self-talk and parallel talk.* In *self-talk* we describe our own actions as we engage in parallel play with the child. If the child is building a block tower, we copy the tower with our own blocks, saying as we do, "I'm building. I'm building with blocks. See my blocks? I'm building." Self-talk provides a clear and simple match between actions and words. By using the child's actions and matching our own words and actions to them, we model how to comment on our actions with language.

In a sense, in *parallel talk* we provide self-talk for the child. Instead of talking about our own actions, we talk about the client's, providing a running commentary, something like the play-by-play at a sporting event. To take the same block-building example we used before, parallel talk might sound like, "You're building. You put on a block. You did it again. You put on another block. Now it's big! You're building a big one!" Parallel talk also can help us make connections to children with severe disorders whose choice of actions may not be typical. For example, children with autism, if given a set of toys, may use them in unconventional ways. Instead of building a tower with blocks, an autistic child may smell them or focus on the texture of the rug underneath the blocks. Parallel talk allows us to share this child's focus. Again, we talk about the child's focus of attention; for example, "You see the rug. It's green. It's a green rug. It's soft. Can you feel it? It's soft. The blocks are on the rug. They're on the soft, green rug."

Self-talk and parallel talk are helpful for children who are not talking at all in the clinical setting. The clinician's use of these techniques maximizes the chances that the child will use the model in producing a spontaneous utterance. Once the child does, the clinician can respond with other techniques included in the indirect language stimulation approach. These techniques are designed to provide a verbal response that is highly contingent on the child's own utterance. Let's look at these contingent response possibilities, too.

2. *Imitations.* We often ask children to *imitate* what we say in intervention. But instead, we can turn the tables and imitate what the child says. Folger and Chapman (1978) showed that adults often repeat what normal toddlers say, and that when they do, there is a substantial probability that the child will imitate the imitation. Research suggests that children who imitate show advances in language development (Carpenter, Tomasello, & Striano, 2005). Moreover, we know that anything that increases the amount of child talk is associated with acceleration of language development (Gallagher, 1993; Hoff-Ginsberg, 1987; Sachs, 1983). The more the child says, the more the opportunities exist for practice of phonological, lexical, and syntactic forms and the more opportunities there are for feedback. If the child repeats our imitation, we can go on to use some of the other forms of contingent responses available in indirect language stimulation to provide more focused and extensive feedback. Or, alternatively, we can use the child's imitation to initiate a repeated back-and-forth exchange that will help the child develop this basic turn-taking structure for conversation.

3. *Expansions.* In *expanding* the child's utterance we take what the child said and add the grammatical markers and semantic details that would make it an acceptable adult utterance. For example, if the child puts a toy dog in a dollhouse and says "doggy," or "doggy house," this could be expanded as "The doggy is in the house." Expansions have been shown to increase the probability that a child will spontaneously imitate at least part of the expansion (Scherer & Olswang, 1984). Again, any talk is good talk in our book. It's practice, and it gives us yet another opportunity to provide additional contingent feedback. Moreover, Saxton (2005) reviewed literature to suggest that expansions specifically have been associated with grammatical development for a number of structures in a number of diagnostic groups. In more current literature, these are sometimes called *recasts* (Camarata & Nelson, 2006).
4. *Extensions.* Some writers call these responses *expatiations* (Fey, 1986). They are comments that add some semantic information to a remark made by the child. In our "doggy house" example, saying "He went inside" or "Yes, he got cold" could extend this remark. Cazden (1965) and Barnes, Gutfreund, Satterly, and Wells (1983) showed that adults' extensions are associated with significant increases in children's sentence length. Owens (2009) called the latter three kinds of responses—imitation, expansions, and extensions—*consequating behaviors* on the part of the adult. They decrease the amount of information in the adult utterance that the child has to process (Proctor-Williams, Fey, & Loeb, 2001). They do this by taking the form and meaning the child has already expressed and pushing it a small step further, into the ZPD, we might say. All three behaviors increase the likelihood that the child will imitate some part of the *consequating* utterance. This is important because anything that increases the rate of child talk has positive consequences for language development, in general, as we've seen. In particular, these *consequating* remarks provide the child with information about how to encode in a more mature linguistic form the ideas they are already expressing.
5. *Buildups and breakdowns.* Weir (1962) studied the before-sleep monologues of a typically developing 2-year-old child. She found that the monologues commonly contained sequences in which the child took her own utterance, broke it down into smaller, phrase-sized pieces, and then built them back up into sentences. We can do this *breaking down* and *building up* for the client, in an attempt to demonstrate how sentences get put together. We start by expanding the child's utterance to a fully grammatical form. Then we break it down into several phrase-sized pieces in a series of sequential utterances that overlap in content. Let's take the "doggy house" example again. To do a buildup and breakdown on this utterance, we might respond, "Yes, the doggy is in the house. The house. He's in the house. In the house. The doggy is in the house. The doggy. The doggie's in the house." Cross (1978) found that these types of responses, too, are associated with language growth in normally developing children.
6. *Recast sentences.* These are similar to expansions. Expansions, you'll remember, elaborate the child's utterance into a grammatically correct version of the intended sentence type. In recasting we expand the child's remark into a different type or more elaborated sentence. If the child makes the statement

“doggy house,” we can recast it as a question, “Is the doggy in the house?” or a negative sentence (used as a playful denial of the child’s utterance), “The doggy is *not* in the house!” or even a negative question, “Isn’t the doggy in the house?” Camarata et al. (1994); Nelson et al. (1996); and Proctor-Williams, Fey, and Loeb (2001) showed that recast treatment was effective in teaching grammatical forms to children with specific language impairment, but only when the recasts were presented at rates that are much greater than those available in typical conversations with young children (Proctor-Williams & Fey, 2007). Hassink & Leonard (2010) suggested recasts work especially well when they do not correct a child’s form, but simply demonstrate correct use of the target (e.g., Child: “My mom like ice cream.” Clinician: “I’ll bet she eats it every day!”). This finding reminds us that one of the ways therapeutic conversation differs from ordinary talk is in its conscious attempt to greatly increase the “dose” of helpful input it provides. When engaging in any CC language activity, it is essential to focus attention on using our linguistic input to maximize the intensity of our client’s exposure to helpful examples of language.

One particular type of recast sentence has been found in research (Hoff-Ginsberg, 1990) to be particularly helpful to normal children in learning the verb structure of English, a system that gives children with language impairments a particularly hard time. This is the *verbal reflective question*. Verbal reflective questions are recasts that repeat part of the child’s utterance but pass the conversational turn to the child by turning the partial repetition into a question. So if the child says, “doggy house,” a verbal reflective question response would be “The doggy is in the house, isn’t he?” Again, these responses seem to be useful, like the other consequating behaviors we’ve discussed, because they provide a scaffold to elicit talk from the child that is contingent on the child’s own topic. However, Fey and Loeb (2002) found that it was important to provide these recasts only to children for whom the targeted form was within the ZPD. Providing them to children whose language levels were too low did not result in increased learning for the new form. This is one reason that careful assessment of language level is so important; it helps us identify the appropriate “next step” in the child’s language development, so we can provide just the right input to make that step possible.

Indirect language stimulation, then, attempts to provide a simple, accessible model of the mapping between the child’s actions and the language that can be used to describe them. Its purpose is to “tempt” the child to talk by following the child’s choice of activities and topics, providing an attentive and responsive person with whom the client can interact and supplying models of more mature language that are within the child’s ZPD. Research on both children with typical acquisition and those with language disorders suggests that these techniques are indeed helpful in accelerating language growth (see Camarata & Nelson, 2006; Girolametto & Weitzman, 2006; Peterson, 2004; Saxton, 2005, for reviews), particularly at Brown’s stages IV and V of language development (Gillum et al., 2003). Ingersoll (2011) also suggests this approach is useful for eliciting comments from children with ASD, a communicative act that is often very reduced in this population. It’s interesting to note, though, that Shriberg and Kwiatkowski (1982a) found that clinicians did not like the ILS approach, even though the clients did. This finding probably reflects the discomfort many of us feel in leaving the child in some sense in charge of the intervention, relinquishing the control that CD approaches afford us.

Despite this discomfort, in our view, there is a place for indirect language stimulation in our clinical arsenal. For obstinate and unassertive clients it may be the best bet for establishing a relationship that allows them to take some responsibility for communication. For any client who is functioning at a mean length of utterance (MLU) level below three morphemes (where these techniques have been shown to be effective for normally developing children), ILS can be an especially useful adjunct to more structured intervention activities. Augmenting more structured approaches with ILS gives the child a chance to see how the forms being trained are used for real communication and gives the client an opportunity to try for spontaneous usage in a safe and responsive environment with a good deal of scaffolding and support. ILS, then, is an ideal first step for certain developmentally young clients and can be a useful adjunct to the intervention program for any client in the early stages of language acquisition. It is important to remember, however, that, to be effective, ILS techniques must provide high levels of intensity of input. Proctor-Williams & Fey (2007) estimated that it is necessary to provide about one consequating remark per minute in order to make this method work.

We can summarize our discussion of the CC approach to language intervention by saying that it is at the opposite end of the continuum from CD approaches in terms of naturalness, degree of adult control, use of external reinforcement, and adherence to pragmatic principles. Is there anything in between? Fey (1986) suggested that there are approaches that fall midway on this continuum. He referred to these as *hybrid* approaches.

Hybrid Approaches

According to Fey (1986), hybrid intervention approaches have three major characteristics. First, unlike CC approaches, which focus on general communication, hybrid approaches target one or a small set of specific language goals that are identified through the processes we discussed earlier. Second, the clinician maintains a good deal of control in selecting activities and materials but does so in a way that consciously tempts the child to make spontaneous use of utterances of the types being targeted. Finally, the clinician uses linguistic stimuli not just to respond to the child’s communication but to model and highlight the forms being targeted. Munro, Lee, & Baker (2008) showed that hybrid techniques were effective for improving vocabulary and phonological awareness in children with DLD. We’ll discuss several forms of hybrid intervention: focused stimulation, vertical structuring, milieu teaching, and script therapy.

Hybrid intervention combines some degree of structure with opportunities for the child to make selections.

Focused Stimulation

In this approach the clinician carefully arranges the context of interaction so that the child is tempted to produce utterances with obligatory contexts for the forms being targeted. The clinician helps the child succeed in this by providing a very high density of models of the target forms in a meaningful communicative context, usually play. The child is not required to produce the target forms, however—only tempted. Because the clinician provides many models of the target form in a meaningful context, this approach is very effective for improving comprehension of a form, as well as production (Weismer & Robertson, 2006). Box 3-3 gives an example of a focused stimulation approach to teaching use of “is” as a copula.

The example demonstrates how the clinician provides multiple exemplars of the target form in a structured but interactive play context. Note how the clinician first provides opportunities for the client to use the form, but when the child responds with something other than the target, the clinician responds contingently anyway, then goes on to give further models. The clinician gives feedback similar to an expansion when the child makes an unsuccessful attempt. She asks the child to attempt the form, but if the child declines to do so, the clinician simply goes on giving additional models. Weismer and Robertson (2006) provide an extensive review of the evidence supporting the use of focused stimulation to teach language form, content, and use for both monolingual and bilingual children (e.g., Cleave & Fey, 1997; Leonard, Camarata, Rowan, & Chapman, 1982; Robertson & Weismer, 1999; Skarakis-Doyle & Murphy, 1995), when implemented by both clinicians and parents (e.g., Girolametto & Weitzman, 2006; Lederer, 2001; Robertson & Weismer, 1999) for improving both functional comprehension and use of the target structures.

Vertical Structuring

Vertical structuring is a particular form of expansion used like focused stimulation to highlight target structures. Box 3-4 provides an example dialogue that uses vertical structuring. There we see that the clinician responds to a child’s incomplete utterance with a contingent question. The child responds to the question with

another fragmentary remark. The clinician then takes the two pieces produced by the child and expands them into a more complete utterance. The child is not required to imitate this expansion. The fact that children often imitate adult expansions of their own utterances in normal development is the basis for the hope that children with language impairments will take these expanded models of their own intended utterances as a cue for spontaneous imitation. If they don’t, the clinician simply goes on to elicit another set of related utterances from the child and offers the vertically structured expansion again.

Vertical structuring is obviously less naturalistic than standard ILS techniques in that the clinician provides a specific nonlinguistic stimulus, such as a picture; targets a particular form; and attempts to elicit particular language behavior from the child. But it does use a naturalistic response on the part of the clinician and takes the child’s spontaneous utterance as the basis for the clinician response, rather than requiring an imitation. Vertical structuring has been used primarily to target early developing language forms and has been shown to be effective when used for this purpose (Schwartz, Chapman, Terrell, Prelock, & Rowan, 1985). Skarakis-Doyle and Murphy (1995) used the technique to target more advanced language structures (*should*, *must*). They demonstrated that vertical structuring used after focused stimulation enhanced the effectiveness of the intervention. Box 3-5 gives an example of a dialogue that uses vertical structuring to elicit sentences with relative clauses.

Milieu Communication Training

Milieu teaching includes several different techniques that apply operant principles to quasi-naturalistic settings. Hancock and Kaiser (2006) discuss three major components that characterize this approach: (1) environmental arrangement, (2) responsive interaction, and (3) conversation-based contexts that use child interest and initiation as opportunities for modeling and prompting communication in everyday settings. These methods make use of imitative cues and extrinsic reinforcement but do so during interactive

BOX 3-3 A Focused Stimulation Approach to Teaching Copula “Is”

Materials: Toy barn, farmer, farm animals, toy truck that can hold animals.

Clinician: Let’s pretend we’re farmers. We’re taking our animals to the fair. We want to be sure we don’t forget any. Here they are in the barn. I’ll put some in the truck. OK, now the cow *is* in the truck. The horse *is* in the truck. The sheep *is* in the truck. What about the dog?

Client: Bark.

Clinician: Yes, the dog can bark. He says, “Ruff, ruff.” Let’s put the dog in the truck. Now he *is* in the truck. Good! Let’s see. The cat *is* in the barn. Let’s put her in the truck. Good, now she *is* in the truck. The goat *is* in the truck. How about the chicken?

Client: Chick in truck.

Clinician: Yes, She *is*. The chicken *is* in the truck. That’s good. Is the pig in the truck? He *is*. He *is* in the truck. Tell the farmer. Tell him, “The pig *is* in the truck.”

Client: Pig is truck.

Clinician: Good, now everyone *is* in the truck. Now we can go to the fair.

BOX 3-4 Example of Vertical Structuring

Materials: A picture of children visiting a zoo.

Clinician: Look at this. What do you see? (If the child does not respond or makes a remark unrelated to the picture, the clinician directs the child’s attention to a specific referent in the picture and asks again, “What do you see here?”)

Client: Lion.

Clinician: Yes, and what is the lion doing?

Client: Roar.

Clinician: Yes, he’s roaring. The lion is roaring.

BOX 3-5 Example of Vertical Structuring Used to Elicit Sentences with Relatives Clauses

Materials: A picture of children visiting a zoo.

Clinician: Tell me about one of the children in this picture.

Client: This boy sees the lion.

Clinician: Uh-huh. Tell me something else about him.

Client: He’s wearing a baseball cap.

Clinician: Yeah, the boy who is wearing a cap sees the lion.

activities that have been carefully arranged by the clinician to elicit child initiations, necessitate social communication on the part of the client, and provide natural consequences for the communication.

Hart and Risley (1975) introduced the *incidental teaching* method, as one example of this approach. Here the clinician arranges the setting so that things the client wants or needs to complete a project are visible but out of reach. The child selects the topic of conversation by making some kind of request, such as gesturing or looking toward the desired item. The clinician responds first with *focused attention*. This involves moving toward the child, making eye contact, and waiting expectantly to see whether the child will offer a more elaborated request. If not, the clinician asks a question. The question form varies, depending on the clinician's goal. "What?" may be used if the target is simply for the client to produce verbal requests. "Which one do you want?" could attempt to elicit sentences with adjectives. "Why do you want it?" might be used if the goal is sentences with "because" clauses. If this question produces the target response, the clinician provides a confirmation, which includes a model of the target form (Client: "Want red marker." Clinician: "Oh, you want the red marker. Here it is.>"). If the question fails to produce the target response, a prompt is provided. Prompts can be general requests for the target, such as "You need to tell me." Or they can be requests for partial imitations, such as, "Say, 'I need a marker because . . .'" They can also be requests for complete imitations, such as, "Say, 'I want a red marker.'" If the child responds appropriately to the prompt, a confirmation is provided and the communicative goal is achieved (the child gets the marker). If not, one more attempt to prompt is made. If this also fails, the child still gets what he or she wants. The clinician tries again to elicit more elaborated language on the child's next attempt at communication.

A similar method is the *mand-model* approach of Rogers-Warren and Warren (1980). There are two major differences between this and incidental teaching. The first is that the clinician does not need to wait for the child to initiate communication. The clinician carefully observes the child, and when the child seems to show some interest in some aspect of the environment, the clinician "mands" (requests) an utterance with a stimulus, such as "What's that?" or "Tell me what you need." The second difference is that the goals are stated very generally. Rather than specific form or meaning targets, the clinician is merely trying to elicit one-word utterances from some clients, two-word sentences from others, or complete grammatical sentences from more advanced clients. In this way the mand-model approach can be easily adapted to work with groups of clients, where each might have his or her own set of goals, and prompts are individualized to the goals of each client. If the child provides the target response, he or she is verbally reinforced *and* given the desired item ("Good talking! You asked for the marker, so here it is!"). If the child does not, prompts similar to those used in incidental teaching are used.

Warren et al. (2006) Fey et al. (2006), and Yoder and Warren (2001, 2002) discuss an additional variation: *prelinguistic milieu teaching* (PMT). This method is designed for children not yet using spoken language, at developmental levels of 9 to 18 months, although they may be of chronological ages up to 6 years. The goal of PMT is to develop the basic intentional communication skills necessary for early language development by increasing the frequency, maturity, and complexity of nonverbal communicative

acts. Table 3-2 lists the five essential goals of this approach. We'll discuss PMT in more detail in Chapter 7.

Finally, Hancock and Kaiser (2006) discuss *Enhanced Milieu Teaching* (EMT). This method has been shown to be especially effective for children who meet the following criteria: (1) produce some verbal imitation (2) have at least 10 productive words, and (3) are in the early stages of language development, with MLUs from 1 to 3.5. The approach has been used with clinicians, parents, and teachers as agents of intervention, but most of the research on EMT has focused on parent-delivered therapy. It incorporates methods from both incidental teaching and the mand/model approach, using activities like those in Box 3-6.

A large literature base exists on the effectiveness of various examples of milieu teaching. Goldstein (2007); Hancock and Kaiser (2006); Mancil (2009); Mancil, Conroy, and Hayden, 2009; Peterson (2004); Prelock et al. (2011); and Warren et al. (2006) review studies that provide evidence for the usefulness of these approaches with preschool children with intellectual and language disorders, autism spectrum disorders, as well as children from high-risk and low-income families. Delprato (2001), as we saw, used meta-analysis to argue that these techniques lead to better generalization than strict CD approaches. Milieu teaching has been shown to increase children's frequency of talking both to the teacher and to each other (Hart & Risley, 1980; Warren, McQuarter, & Rogers-Warren, 1984) and to be helpful for addressing a broad range of expressive communication targets (Camarata & Nelson, 2006) and to have gains maintained over time (Mancil, 2009). These approaches are particularly useful in small-group or classroom settings in which clinicians want to retain some of the positive aspects of clinician-directed language intervention but to expand their effects to a broader communicative context. They allow the clinician to use imitation, prompting, and cueing during the course of naturalistic activities, thus showing the child how the language being trained works to accomplish real communicative ends.

Script Therapy

Olswang and Bain (1991) discussed script therapy as a way to reduce the cognitive load of language training by embedding it in the context of a familiar routine. Here the clinician develops some routines or scripts with the child in the intervention context. For example, a clinician may institute a routine of placing a nametag on a peg when the client enters the room or always passing out supplies for snacks in the same sequence. Alternatively, the clinician re-enacts scripts the child already knows. These already known scripts could include eating at a fast-food restaurant, for example. In the intervention activity the known script is disrupted in some way, challenging the child to communicate to call attention to or repair the disruption. Disruptions can be accomplished by violating the routine. For example, the teacher can begin to give out cookies before the napkins have been distributed. The clinician can withhold turns, passing over one child when she is distributing drawing supplies. The clinician can violate the normal uses of objects in routines. For example, she can wear the clients' nametags on her head one day, or she can hide objects needed to complete routines. If she locks the classroom each day as the class leaves for recess, she can hide the key and pretend to leave without locking up.

Verbal scripts or routines also can be used in this kind of activity. If the group always begins a session by singing a good-morning song, the clinician can start one day by singing, "Good-night." If the clinician has read the clients a book several times so that the

TABLE 3-2 Goals and Activities for Prelinguistic Milieu Teaching

Goal	Activities
Establish interactive routines to serve as contexts for communication	Imitate child's actions Imitate child's vocalizations Interrupt patterns of action with an adult turn; wait for child to take a turn; perform an action child finds silly, pause for child reaction, repeat When a child performs one part of a routine, perform the act needed to complete it.
Increase frequency of vocalizations	Recast the child's vocalization with a word if he or she is focused on a referent Imitate vocalizations in varying ways: Precisely as child produces them With different sounds and syllables within the child's repertoire With sounds and syllables outside the child's repertoire.
Increase frequency and spontaneity of coordinated gaze	Create a need for communication within a routine in which the child looks at an object, then: Give the child the object or action only if he or she looks at it Verbally prompt for gaze Move the object to your face to get the child to look at you Intersect the child's gaze by moving your face into the child's line of sight When the child looks, acknowledge the look with a pleased facial expression
Increase use of nonconventional and conventional gestures	Create a need for communication within a routine in which the child looks at an object, then: Give the child the object or action only if s/he uses a gesture, such as pointing Pretend not to understand if child fails to gesture; ask "What do you want?" If needed, give a more specific cue ("Show me which one") Give an explicit cue ("Show me!") Model an appropriate gesture Verbally acknowledge when the child complies by producing a gesture
Encourage combinations of gaze, vocalization, and gesture	If the child produces two of the three elements, wait expectantly for the third If the child does not supply it: Ask, "What do you want?" Intersect the child's gaze Model the gesture Model the word Provide feedback and praise

BOX 3-6 Activities Used in Enhanced Milieu Teaching

- Choose materials of interest to child; arrange environment to support engagement and requesting.
- Use environmental arrangement to elicit child initiations.
- Mirror child actions to take a nonverbal turn; pause and wait expectantly following an adult remark to give child a chance to take a turn.
- Recognize and respond to what child communicates verbally or nonverbally.
- Expand child utterances to those at child's current ZPD.
- Use models following child requests to elaborate child form.
- Use request or questions that give child a limited choice for responses.
- Use time delay/expectant waiting to elicit child speech.

children know it by heart, she can misread various portions. If a finger play such as "Where is Thumbkin?" is part of the group's routine, the clinician can purposely hold up an incorrect finger for one part of the rhyme. If the class has been learning nursery rhymes, the clinician can substitute words that rhyme but are inaccurate ("Humpty Dumpty sat on a wall; Humpty Dumpty had a

Finger plays can be used in script therapy.

great *doll*”) or that don’t rhyme (“Tom, Tom, the piper’s son/Stole a pig and away he *walked*.”).

Violations of verbal scripts also can be encouraged in clients, as a way to provide a scaffold from a known form to a slightly different or more complex variant. For example, a particular book, song, finger play, or poem can be included as part of every intervention session. The clients can be encouraged to “play with” this script once it has been overlearned. These violations can be pegged to specific intervention goals. For example, clients can be asked to change some words in the script to their opposites, if opposites are a target concept in the intervention. They can be asked to recast a present-tense text in past tense or vice versa. (“Let’s read *The House that Jack Built* as if it is just happening now. I’ll do the first page. ‘This is the house that Jack *builds*’ [or ‘*is building*’]. ‘This is the malt that lies in the house that Jack builds.’ Now you try the next page.”)

Literature-Based Scripts and Interactive Book Reading One variant of script therapy that has been subject to a good deal of research involves scripts based on picture and story books. This approach capitalizes on the familiarity and naturalness of interacting with young children around story book reading. Cole, Maddox, and Lim (2006) argue that book-sharing contexts are particularly effective because the book provides parents with greater opportunities for asking questions, making comments, and taking turns than do unsupported conversational settings. But they emphasize that simply reading to children is not enough, the reading must be accompanied by specific interactive techniques if it is to be effective as a language therapeutic tool. They review studies (e.g., Crain-Thoreson & Dale, 1999; Dale et al., 1996; Hargrave & Senechal, 2000) showing that children with language disorders associated with a variety of disabilities, as well as children with

limited English proficiency (Lim & Cole, 2002), benefit from interacting with adults who use specific picture book interaction methods. They also cite studies demonstrating that clinicians can teach parents, teachers, and librarians to use and disseminate these techniques (Crain-Thoreson & Dale, 1999; Dale et al., 1996; Huebner, 2000). The critical pieces of this method include the following:

Commenting: The adult notices what the child is interested in on the page, makes a comment, and waits for a child response (e.g., Child points to picture of dog; adult says, “Our dog looks like that one!”)

Asking questions: The adult asks a question at the child’s language level about what the child has shown an interest in on the page (e.g., Child looks at picture of dog and says, “Dog”; adult says, “What shall we call that dog?”)

Responding by adding a little more: After the child talks, the adult expands, extends or recasts the child’s remark, then waits for the child to take a turn. (e.g., Child says, “Go on bus”; adult says, “Yes, they’re getting on the bus. They’re ready for school.”)

Giving time to respond: Adults consistently use expectant waiting before giving another remark, allowing the child an opportunity to take a turn

Using the Continuum of Naturalness

Are naturalistic activities always better than “unnatural” ones? Fey (1986) argued that highly naturalistic activities are best only if they improve the child’s language. If two activities are equally effective in getting a child to produce a form or function he or she has not used before, then the naturalistic activity would be preferred, since it will presumably be more helpful to the child in moving the new form into everyday usage. But if the less naturalistic activity is more efficient in eliciting usage of the new form or function, the unnatural activity is the better choice.

Remember the argument the behaviorists use? They remind us that children with language impairments have been engaging in natural language activities since they were born and have not been able to take advantage of them the way normally speaking children have. Children with language impairments have particular difficulty abstracting conventional language structures from natural interactions. Some children with language impairments are excellent communicators. They get messages across with gestures and vocalizations very effectively and in a natural communicative environment can continue to do so indefinitely. Their communication will not necessarily change in an intervention program that merely provides more of the natural opportunities and consequences that they have been exposed to throughout their history.

So the point to be made about naturalness is that, all things being equal, a natural activity is better than an unnatural one, but only if all things are equal. If it can be shown that the child gives a greater number of correct responses in an unnatural activity, then the unnatural activity is better for eliciting the form, at least initially.

When thinking about naturalness in intervention, it is important to recall, too, that as Craig (1983) pointed out, communication can look natural to the child but does not have to be natural to the clinician. It is possible to design intervention contexts that appear to be natural but actually require a good deal of contrivance on the part of the clinician. For example, a clinician could set up a situation in which a child is supposed to build a block structure, a naturalistic activity. The clinician could give the child

Interactive storybook reading builds language and preliteracy skills.

all the materials, then ask for each piece he or she needed to build a duplicate of what the child was building. Each request could be framed in an exactly parallel way, “Can you pass me the [X] please, [client]?” Clearly, this is not a natural way to talk. In real conversation we would vary our request forms, make a request for several items at once, just take some things that were in reach, and so on. But this stilted, unnatural style provides a clear and consistent model of how the client is to phrase a polite request. Suppose the tables are then turned and for the next building project the clinician has all the materials. The child has been exposed to an intensive dose of the forms he or she needs to request the desired materials.

So, in dealing with the continuum of naturalness in intervention, we have several options. We can complement CD activities with more naturalistic hybrid or CC activities throughout the intervention program. Or we can engineer the environment, carefully designing settings and activities that appear natural from the child’s point of view. A third option was also presented by Fey (1986). We can use highly structured, clinician-directed activities and modify their format to increase the extent to which they resemble real-life communication. Fey gave the following guidelines for increasing the naturalness of CD activities.

Make the Language Informative

For example, instead of having the client simply imitate the clinician’s “is (verb)-ing” description of a picture (“The boy is jumping.”), we can display two similar action pictures and describe one, asking the client to point to the one we’re talking about. Then we can give the client the same two pictures and ask him or her to describe one so the clinician can point to the picture being talked about. If the client chooses to imitate the same description as the clinician (“The boy is jumping.”), well and good; a drill-like response has been given, and the clinician can point to the matching picture. If the client chooses to describe the other picture and uses a correct “is (verb)-ing” form, well and good again. If the client describes either picture with an incorrect form, the clinician can feign confusion, present the correct form as a model, and ask the client to give him or her another chance (“I’m not sure I heard you right. Did you say, ‘The girl is running?’ This picture shows ‘The girl is running.’ Tell me again which picture you want me to point to, so I can be sure to get it right.”).

Increase the Motivation to Communicate within the Task

This principle concentrates on getting the client to initiate communication within the CD format. One way to do this is to use a barrier or have the clinician and client sit back-to-back and talk to each other on toy telephones. In this format, the clinician can make a comment designed to pique the curiosity of the client to find out more about the clinician’s topic, which is hidden from the client’s view. In an activity designed to elicit questions, for example, the clinician can say, “WOW!” The client will presumably want to know what the excitement is about and initiate further communication by asking a question. Or, if the clinician wants to elicit negative statements, grossly false assertions can be made and the client can be allowed to correct the clinician by pointing out the error. The clinician might show the child a set of pictures and describe each one with an incorrect verb (for a picture of a boy jumping, the clinician might say, “He’s sleeping. Uh-oh, I think I made a mistake. Can you straighten me out?”).

Use Cohesive Texts

Many CD intervention activities have the child respond with a series of utterances that are syntactically related, in that they have the same form, but are semantically unrelated. In real conversation, though, there is usually a topic about which several related remarks are made. We don’t usually say, “A boy is jumping. A girl is running. A dog is sitting.” We usually establish a topic of conversation and then elaborate on it; for example, “A girl is running. She’s going very fast. She’s going over the finish line now. She wins the gold medal!”

Lee, Koenigsknecht, and Mulhern (1975) dealt with this problem in their *Interactive Language Development Teaching*. This CD program comprises a series of stories, each of which targets several syntactic forms. The clinician reads a story that is illustrated with simple flannelboard figures and contains examples of the target form. A question is then asked that is, essentially, a request for the client to imitate one of the statements heard in the narrative. The “exchange techniques” given in Box 3-7 are used to con-
 quate the child’s response so that the intended target is produced fully and accurately. Box 3-8 gives an example of an *Interactive Language Development Teaching* lesson.

Clinicians also can develop their own materials to serve the same purpose. For example, in eliciting use of auxiliary “can,” the clinician could use a picture book about dressing. The clinician can show each page of the book to the child, while saying, “Here are some things my friend Sam can do. Sam can put on his shoes. Sam can put on his socks. Sam can put on his shirt,” and so on. “Now let’s talk about what you can do. Look at each page. Tell me what you can do to dress yourself. Here is a boy. He can put on his shoe. What about you?”

Move from Here and Now to There and Then

When first attempting to teach language use to developmentally young children, parents and clinicians both use language to talk about objects and events in the immediate environment. This helps the child to see how language is used to map, or refer to, things in the world. But eventually children begin to use language to convey new information about things that are not present in the here and now. This shift is important. It shows that the child realizes that language is primarily used, not to tell people things they can see with their own eyes, but to impart information that is not present in the immediate environment. This ability to use language to talk

BOX 3-7 Interchange Techniques

(In response to client’s utterance. “There one more.”)

1. Complete model: a prompt to imitate (“There’s one more”)
2. Reduced model: a prompt to imitate that contains only a portion of the target response (“There’s . . .”)
3. Expansion request: the clinician asks for an expansion but does not present a model (“Tell me some more. Say the whole thing.”)
4. Repetition request: the clinician asks the client to repeat his or her utterance but does not present a model. (“What did you say? Tell me again.”)
5. Self-correction request: the clinician asks the child to monitor his or her response (“Did you say that right?”)

BOX 3-8 Sample Lesson from Interactive Language Development Teaching

Concepts: baiting a hook, camping, fishing, hurrying

Vocabulary: bait, campfire

Flannel-board materials: figures of Mommy, Daddy, Timmy, Bobby; cutout of tent, table, four fishing poles with strings and hooks, worms, pond, boat

ELICITED STRUCTURES**Primary Emphasis**

Personal pronouns: he, she, his, her, him, we, us, our, them, their, they

Main verbs: -s, -ed, am, are, can + verb, will + verb, do + verb, could + verb, should + verb, does + verb, did + verb

Secondary verb: gerund

Negative: couldn't, uncontracted negative

Secondary Emphasis

Secondary verbs: later-developing infinitives

Interrogative: Reversal of modal and obligatory do

NARRATIVE

This is Mommy. Who is this?
 This is Daddy. Who is this?
 Mommy and Daddy are on a camping trip.
 Mommy and Daddy are fixing breakfast on their camping trip.
 They are fixing breakfast
 They are hungry. What are they doing?
 Where are Bobby and Timmy?
 I do not see them. Where are they? Do you see them?
 Here are Timmy and Bobby!
 They were playing in the woods.
 They smelled the bacon so they came back.
 Why did they come back?
 Timmy and Bobby say: We're hungry.
 Mommy and Daddy say: We're hungry.
 Mommy says: Breakfast is not ready yet. We will have to wait because breakfast is not ready.
 What does Mommy say?
 Now breakfast is ready.
 Mommy says: Breakfast is ready. Come and eat. Come and eat, because breakfast is ready.
 What does Mommy say?
 Everyone is sitting around the campfire.
 Timmy says: I wish we could stay longer. This is fun. I wish we could stay longer.
 What does Timmy say?
 Bobby says: Couldn't we stay. Daddy? Couldn't we stay?
 What does Bobby say?
 (Lesson continues to address other goals listed above.)

TARGET RESPONSE

This is Mommy.
 This is Daddy.

 They are fixing breakfast.

 I do not see them.

 They came back because they smelled the bacon.

 We will have to wait because breakfast is not ready.

 Come and eat because breakfast is ready.

 I wish we could stay longer.
 Couldn't we stay?

about events removed in time and space is what frees the child from dependence on the immediate context. Eventually, this shift allows the child to use the kinds of decontextualized language that are important for literacy development and school success (Nelson, 2005; Wallach & Miller, 1988; Westby, 2005).

Spradlin and Siegel (1982) discussed the importance of teaching children to use language to accomplish things that cannot be accomplished in other ways. One basic function of language is to tell people about things they do not already know, about places they have never been, or about things they have never seen. So it seems important to give children with language impairments the opportunity to practice using language for this informative pur-

pose. One way to increase the naturalness of CD intervention is to contrive contexts for children to drill forms in such a way as to use them in reference to "there and then" rather than "here and now."

But for many children with language impairments, this is no easy task. Fey (1986) suggested that one way to scaffold this kind of activity is to talk about events outside the immediate context and to rely on familiar activities or "scripts" for doing so. For example, a child working on basic subject-verb-object (S-V-O) sentence structures might make popcorn with the clinician. Each step in the process can be labeled by the clinician and, using a CD format, repeated by the child. ("We get the popcorn. We fill the popper. We plug in the popper. . . .") After completing the activity, the clinician

can invite a parent, peer, aide, or puppet to join the client in eating the popcorn. The client can then be asked to retell the steps in making popcorn to the confederate (“You get popcorn. . .”). This activity requires the client to talk about a nonpresent set of actions without using props, but provides the strong scaffold of recent personal experience.

Using these techniques to increase the naturalness of CD activities can be another means toward our end of helping the child not only to produce target forms, but also to use them to communicate. Whether we use a mix of approaches, engineer the environment to make intervention appear natural from the child’s point of view, modify CD approaches to increase their naturalness, or do all of these, our overriding objective is to make the language we teach to children a meaningful tool for accomplishing social goals.

Intervention Activities

Once a general approach to intervention for a specific set of goals has been established and a mix of approaches for the entire intervention program has been set out, we need to plan the individual activities that will comprise the “meat” of the intervention. Although it is impossible in a textbook to outline all the activities that can be part of an intervention program, we can talk about some features of these activities so that the clinician will have a menu of choices for putting activities together. Let’s see how we can structure specific activities to achieve changes in clients’ language skills.

Structuring Intervention Activities to Maximize Learning

Bayles (2011) and Gillam and Loeb (2010) identified several essential ingredients that appear to be associated with enhanced learning in intervention settings. These principles are drawn both from evidence based on randomized controlled trials of a range of intervention procedures, as well as from literature on neuroplasticity, which highlights the conditions associated with the brain’s reorganization by experience, which is the definition of *learning*. These elements were found to be present in the effective intervention methods tested, and were associated with changes in the brains of individuals who learned new skills. They are summarized in [Box 3-9](#). We will discuss some of these ingredients in more detail in this section. As we plan intervention activities, though, it is useful to keep these principles in mind and attempt to incorporate as many as we can into each clinical encounter.

Modifying the Linguistic Signal

When we deliver language intervention, one of our most important tools is our own linguistic input to the client. Linguistic input is one of the major means of structuring what the child has to deal with in the intervention. Because it is such an important tool, we need to think very carefully about the input we present to the child, in terms of both its meaning and its formal properties. Linguistic input can be manipulated in many ways to make it a more effective, efficient vehicle for encouraging change in the client’s language use. As language pathologists, our linguistic signal is our richest and most flexible device for accomplishing this change. That’s why we have to use it wisely. Let’s look at some of the ways we can modify our input.

Rate

Reducing the rate of speech is a fundamental means of modifying input. In speech to normally developing young children, adults produce fewer words per minute and take longer pauses between words and utterances than they do in speaking to adults (Sheng,

McGregor, & Xu, 2005). Talking more slowly may help the child by reducing the number of units that need to be processed per unit time, by providing somewhat more stable auditory models, and by encouraging increased clarity of articulation on the clinician’s part, thus supplying a higher-quality model for the child. Furthermore, in activities involving choral speech or song, the clients’ speech-motor capacities may preclude their participation at normal speech rates. Slower delivery gives them more time to formulate and execute their speech-motor capacities. Montgomery (2005) and Weismer and Hesketh (1993) have shown that slowing the rate of speech improves both comprehension and production of new words by children with language impairments. Weismer (1996) showed that reducing speaking rates also aids in the acquisition of grammatical morphemes in children with language disorders. Cirrin & Gillam (2008) suggested slowed presentation rate can be helpful in vocabulary development for school-aged children.

Slowing down the rate of speech is often easier said than done, particularly when working with a group of children or with very active clients, whose behavior tends to influence our own sense of pacing. Consciously trying to speak slowly and distinctly, conveying a sense of calm control, is a good habit for a clinician to cultivate. When working in a script therapy format using songs, rhymes, or finger plays, slowed rate is especially important. If the goal of these activities is to allow the client to internalize a verbal script, it is vital that the script be easily accessible. Singing may be more fun when it is “up tempo,” but it will do the client less good. In our own work in supervising student clinicians, we have often seen students leading a group of young children in a song, the students themselves merrily singing away at normal tempo while the clients sit silent, unable to keep up the pace. When the clinicians are encouraged to slow the song down, the clients often begin to join in. Again, a slower-than-natural rate of speech, song, and rhyme often helps the language-learning child.

Repetition

“If I’ve said it once, I’ve said it a hundred times.” This should be the language clinician’s motto. Research has shown that children with language disorders need many more exposures before acquiring language forms and concepts than typically developing children do (Camarata & Nelson, 2006; Proctor-Williams, Fey, & Loeb, 2001). In normal development, clear examples of the match between a particular linguistic form and its nonlinguistic referent are often few and far between. For children with normal development, these few widely spaced exemplars may be enough. But children with language disorders are, by definition, less efficient language learners. They may need many more experiences of this match concentrated in relatively short periods of time to assimilate them. Intervention that exposes clients to multiple examples of target forms and their nonlinguistic mapping may be a key to their learning.

This implies that intervention can sometimes entail providing clients with what they would normally get from natural interactions, but simply increasing the frequency of both these focused interactions and the particular forms used within them. It could be taken to suggest a rationale for ILS and other naturalistic forms of intervention. It also could be seen as a rationale for drill forms of intervention or for focused stimulation, which also supply numerous examples in concentrated formats. The point is that there are a variety of ways, both naturalistic and contrived, to provide a client with intensive experience with form-meaning matches. What matters is providing the repetition.

One additional way to supply the child with useful, repetitive information about how language works is to provide contrasting

BOX 3-9 Essential Ingredients of Successful Therapy*

PRINCIPLE	DESCRIPTION	EXAMPLE STRATEGY
Intensity	Daily, 1–1.5 hour sessions for 5–8 weeks	Use intensive cycle scheduling (see Ch. 12) to provide intervention to a smaller number of students on a more intensive schedule for a limited number of weeks; use summer programs to provide intensive intervention opportunities.
Active engagement	Sustaining a client's active involvement in intervention tasks by monitoring and guiding attention through preparatory, selective, and maintenance cueing, and choosing activities that are appealing enough to sustain client engagement.	Provide a pre-attentive stimulus ("Look at this!"), and promote selective attention and maintenance of attention by carefully monitoring child focus, pointing out what the child should look at/listen to, guiding attention back to the relevant stimuli when it strays, and providing engaging social interaction to accompany the learning activities.
Feedback	Information about the accuracy of client response.	Give a mildly unpleasant response for incorrect answers, such as a "clunk" noise made by a computer or instrument; give information when response is correct as to <i>why</i> it is correct ("That's right; you remembered to say 'is' in your sentence!")
Reinforcement	Delivering a reward following a correct response that increases the rate or likelihood of the appearance of the target behavior.	Reinforcements must be carefully selected that are powerful for the individual client. For some, social praise may be adequate, but many will require more extrinsic rewards, such as stickers, prizes, edibles, or opportunities to engage in preferred activities. Intrinsic reinforcement, or the achievement of the client's communicative goal (saying "want teddy" and getting the teddy), can also be powerful.
Repetition	Providing many opportunities for clients to use or process a new target.	Drill play activities, contrastive drills, repeated exposure to scripts.
Use distributed practice	Provide short, intense periods of practice for new forms; intersperse with practice on other forms or instruction in new targets.	Structure sessions to include 5–10 minutes of drill/drill-play on new or recently learned targets, then move to introducing initial instruction on another target, rehearse a script, or provide indirect language stimulation, then provide another short bout of intensive practice.
Specificity	Children learn what they are <i>taught</i> ; to teach a skill, provide instruction, and practice on that specific skill, not on skills thought to be prerequisite or related to it.	To teach language comprehension, provide experiences in which words and sentences are presented along with clear examples of their referents and provide practice in observing and interacting with the specific words, sentences, and referents targeted. Avoid using "auditory processing skills," such as discriminating non-speech sounds or locating environmental sounds, to teach comprehension.
Control complexity	Teach in the zone of proximal development; provide activities the client can do with the clinician's support but cannot do without it.	Provide language a few morphemes longer than the client's average utterance length; adhere to the principle of only one new thing at a time: have client produce a new form in a familiar function or a new function using a familiar form.
Minimize error responses	Provide adequate cueing and scaffolding so child responses are correct almost all the time.	Rehearsing errors can strengthen them as a response. Always provide corrective feedback when a client makes an error; encourage them to repeat the correction.
Work within schemas	Embed practice of new forms and functions within familiar sequences of actions.	Practice new language forms in well-known contexts; e.g., practice asking yes-no questions in a game of "Go Fish," practice using polite requests by "shopping" at several pretend "stores."

forms from which the child can induce linguistic rules. This approach is sometimes called "inductive teaching" (Connell, 1989) or "contrastive drill" (Fey, Long, & Finestack, 2003) and is frequently used in both phonological and language intervention. This approach provides the client with a large number of examples of the operation of a linguistic rule, presented in a concentrated manner. If the goal were use of plural forms, the client might be shown a set of picture pairs. Each pair would contain one card with

a picture of a single item and one card with a picture of more than one (not always the same number) of the same item. The clinician would then go through the sets, naming each picture with an appropriate singular or plural label for the client ("cat/cats," "dog/dogs," "bike/bikes," "car/cars," and so on). The clinician might then, after the multiple exemplars, explain the rule in simple terms for the child ("When we see more than one, we put an /s/ sound at the end."). The client could then be asked, with help from the

clinician, to label the same sets of pictures. When success on this task is achieved, a new set of pictures that the child has not heard labeled could be tried.

Although adults see repetition as redundant and boring, it may not be so for the child, as you know if you have ever heard a child ask to watch a video he or she has already seen a dozen times. It is not necessary, as it is in adult conversation, to come up with a new and different way to say the same thing each time. In intervention the opposite may be true. We should strive to say the same thing the same way in the same context over and over and over. In this way we can maximize clients' opportunity to add it to their repertoire.

Increasing Perceptual Saliency through Prosody and Word Order

In speech to normally developing young children, adults typically stress more than one word per utterance and use exaggerated intonation contours. This style of speech does not sound natural in other contexts, but it may help the very young listener direct attention to the auditory signal and highlight the segments containing the most salient information. These prosodic changes are available for talk in intervention, too. Weismer and Hesketh (1993) showed that children with language impairments produced new words that had received emphatic stress during an intervention program more often than they produced words that had been trained with neutral stress. Weismer (1998) showed that this effect was specific to the production modality. These findings suggest that intonational highlighting helps get children to produce new structures. Sheng et al. (2005) called this complex of changes clinicians make in their speech to highlight language forms for clients a *therapeutic register*. Their research suggests that this register takes time and experience to acquire, so beginning clinicians will need to consciously practice and cultivate it.

Fey (1986) and Weismer and Robertson (2006) discussed a second means of increasing the perceptual saliency of language forms: by varying word order. Some forms that are particularly difficult for children with language-learning problems, such as auxiliary verbs and forms of the verb "to be," are usually found in the middle of sentences where they receive very little stress or intonational highlighting. One way to make these forms more perceptually salient is to present them in sentence variants that naturally place stress on them, such as questions that put them in the initial sentence position ("Will he ride the bike?" "Is he here?") or elliptical responses to questions that put them in final position ("Who will ride the bike? He will." "Where is Thumbkin? Here he is."). Using these forms as initial instructional contexts for auxiliaries and copulas avoids unnatural stress conditions in declarative sentences. When usage reaches criterion in these more perceptually salient contexts, efforts could be made to generalize the forms to their less marked variants in declarative sentences.

Controlling Complexity

When talking to very young children, adults generally produce sentences about two morphemes longer than the child's MLU (Paul & Elwood, 1991). The sentences parents produce when talking to normal language learners are shorter than those they use when talking to adults (Sheng et al., 2005). They also are semantically simple in that they generally use a limited vocabulary to refer to concrete objects and perceptions in the child's immediate environment (Chapman, 1981). But they are not simplified syntactically. Parents produce many questions when talking to young children, rather than more straightforward declaratives. And their sentences are fully grammatical and well formed—in fact, more so than sen-

tences spoken to adults, which often contain garbles and false starts (Owens, 2005). So it would seem that normally developing children learn language from a semantically restricted but syntactically well-formed database.

What does this imply for the complexity of language used in intervention? Our answer would be that we should adhere to the same principles. Our sentences should be slightly longer than those the child is using, they should refer to concepts that are semantically accessible to the child, and they should be well formed. Some clinicians "simplify" their input by leaving out function words and grammatical details, producing instructions such as "Get ball." They believe that these utterances are easier for children to process, so they model exactly the kinds of sentences the children are likely to produce.

Our belief, shared by Chapman (1981); Fey, Long, and Finestack (2003); and Hubbell (1981), is that the sentences children hear should, like those heard by normally developing children, be slightly longer and more advanced than those the child currently can produce and include only grammatically correct forms. For children whose comprehension skills are ahead of their current levels of production, the inclusion of grammatical markers in the linguistic input, even if the child cannot reproduce them in his or her own speech, helps to build an accurate auditory image of what well-formed sentences are supposed to sound like. Incorporating grammatical markers in the utterance gives it a rhythmic frame that may eventually help the child fill in the slots created by the rhythm. It also gives children additional exposure to these forms and, as we've seen, children with language impairments need higher levels of exposure before forms are learned. Furthermore, there is no evidence that simplifying sentences to telegraphic forms helps children to understand them (Fey, Long, & Finestack, 2003), although there isn't very strong evidence that about the use of well-formed sentences, either (van Kleeck et al., 2010). Still, Hassink & Leonard (2010) review evidence suggesting that children exposed to more complex input show greater comprehension of complex sentences than children whose input contains fewer complex examples. Semantically constrained, well-formed, grammatically correct input just slightly more complex than the child's own does not hinder, but may help, language development.

Obligating Pragmatically Appropriate Responses

When using linguistic stimuli to elicit talk from a client, we should try to elicit language that is not only semantically and syntactically correct, but pragmatically appropriate. This suggests that if we want a client to produce a whole sentence as a response, our linguistic stimulus should obligate that form and not provide a context for an elliptical sentence. For example, if we want a client to produce, "He is running," we should not use the linguistic stimulus, "What is the boy doing?" The pragmatically appropriate response to this question is, "running." To have the client give this response, and then to tell him or her, "No, say the whole thing," in effect teaches a pragmatic error. If we want "He is running," as the response, we had better choose a stimulus that properly evokes this form. For example, we might say, "Let's look at these pictures. Here, the girl is running. Here the dog is running. Now you tell me about the boy."

There are times when the elliptical response may be the one we want. For example, we may decide to elicit elliptical responses to questions containing inverted auxiliaries to highlight these forms perceptually. In this case a question such as "Will he run?" will elicit the elliptical auxiliary form, "He will," if we make it a rule of the game that the child cannot say "yes" or "no" but

must use some other words as an answer. This format supplies linguistic input that elicits the target form in a pragmatically appropriate context.

Careful selection of linguistic stimuli is one of the most important aspects of our clinical work. It is one thing that allows a trained clinician to provide a more efficient and effective form of linguistic input to a client than an untrained conversationalist. We have an obligation to show the child not only how to produce a syntactically correct sentence but also how to choose which of many possible forms of the sentence is pragmatically appropriate in a given linguistic context. That is, part of our job is not only to teach the child what to say but also when to say it. To tell a client to “say the whole thing” when we have given a stimulus that normally elicits less than the whole sentence violates this obligation. We fulfill our mission to teach language as real communication when we create the linguistic context that obligates a target sentence form in a pragmatically appropriate way.

Determining Dosage

Intensity is one of our principal ingredients in effective intervention, but *how* intense does intense need to be? Ukrainetz (2007) reviewed data and concluded the 10 to 20 hours of phonemic awareness instruction is enough to allow children with DLD to achieve phonemic awareness skills sufficient for beginning reading and spelling. But beyond that, very little empirical evidence exists to guide us in determining optimal intensity for the wide range of communication skills that SLPs address (Warren, Fey, & Yoder, 2007). Proctor-Williams (2007) reviewed evidence on dosage in intervention, and found scant support for identifying any ideal, generalized total intervention duration, but did conclude that distributed practice within sessions and throughout the treatment program appears to be more effective than massed practice (the “drill and kill” approach, involving long periods of repetitive practice). Thus, although the systematic evidence is not yet available, it is likely that daily, intensive sessions involving distributed practice for a few weeks or months will be more effective than the current standard schedules of two to three 30 to 45 minute sessions per week for an academic year. Ways to accomplish these more intensive schedules will be discussed in more detail in Chapter 12.

Determining the Intervention Modality

Besides deciding how to manage the input to the child in the intervention program, we must decide how we will require the child to respond. This decision involves choosing the modality of the child’s communication, and again we have a range of choices available. Let’s explore what some of these choices are.

Comprehension versus Production

One fundamental decision we make in intervention is whether we work toward the child’s ability to show that a target was understood or whether we require that the child use the target in his or her own speech. In normal development, children sometimes use forms, such as correct word order, before they show the ability to comprehend the same forms (Chapman & Miller, 1975; Paul, 2000c). So it is not necessarily true that comprehension precedes production. It follows that it is not always necessary to train comprehension before having a child produce a target form.

For forms and functions that assessment indicates are comprehended but not produced, production training is clearly indicated. Fey (1986) argued that such targets should be high priorities for production training, since they are clearly within the child’s ZPD and the child is “ready” to learn to use them. But what about structures and meanings that assessment indicates are neither

comprehended nor produced? Should they be targeted for production training, for comprehension, or not at all? Behaviorists (e.g., Guess, Rutherford, & Twichell, 1969; Lovaas, Berberich, Perloff, & Schaeffer, 1966; Sundberg & Michael, 2001) have stressed production, in imitation, as a first step in language learning. They believe that to be learned, behavior must be reinforced, and to be reinforced, it must be produced.

Lahey (1988), on the other hand, emphasized the fact that equivalent comprehension and production responses are often not present in normal language learners. She argued that a child should be exposed through multiple meaningful exemplars in the input language to forms that the child does not have in the comprehension repertoire. But she concluded from her review of research on comprehension versus production training that comprehension responses, such as pointing to contrastive stimuli, do *not* need to be trained before production of the forms is targeted. Guided production activities appear to facilitate both comprehension and production of new forms in children. What’s more, Fey et al. (2010) found no compelling evidence that interventions that include listening only, auditory discrimination, or listening to acoustically modified input make any significant contributions to auditory, language, and academic outcomes in children with DLD.

In light of this discussion, we would suggest that for forms the child comprehends, production training should be a high priority. For forms and functions that the child does not yet appear to comprehend, but that are chosen as intervention targets on the basis of other considerations we’ve discussed, an input component should be part of the intervention plan. This might include focused stimulation activities or CC activities that provide multiple opportunities for the clinician to demonstrate use of the structure in context. These approaches should be presented along with activities that elicit production of the target. It is not necessary to wait until the child demonstrates comprehension in pointing activities before trying to elicit the use of target forms.

Augmentative and Alternative Modalities

Speech is the most universal form of human communication. A child who can speak will have the most direct access to the greatest number of communication partners. For some children, though, speech is simply not a realistic option. These children have severe deficits in hearing or oral-motor structure or function that prevent them from using vocal communication. It might seem, on the surface, that these children should be easy to identify. But this is not always the case. Remember when we talked about etiological models of language disorders? We said that the etiology doesn’t always explain the language level that a child attains. For example, you might have two children with the same level of hearing, one with very intelligible speech and one with almost none. One may need to use signs as a form of communication, whereas the other does quite well with spoken language. Moreover, some children do not have any obvious barriers in sensory or motor domains, but simply do not begin speaking; children with moderate to severe levels of intellectual disability sometimes present this picture, as do some children with autism spectrum disorders. For clients who present these profiles, Beukelman and Mirenda (2005) advocate a “communication needs” model for delivery of augmentative and alternative communication (AAC) services. In this model, children who need a means to communicate because of a lack of speech are provided with some communication system, regardless of whether they have identifiable barriers to vocal expression. Binger and Light (2006) suggest approximately 12% of young children receiving special educational services make use of AAC.

Once the decision to adopt an alternative form of communication is made, a variety of communication systems are available to us. The process of choosing an AAC system has two components: *choice of the symbols* to be used and *choice of the interface* between communicator and the system, or how the child will access the symbols.

Symbols can be either aided or unaided. Unaided symbols include gestures, vocalizations, and body language. Aided symbols include productions that require some tool outside the client's own body. Examples of aided systems include objects, pictures, graphic symbols (such as Blissymbols [Figure 3-5]), and alphabet letters. Both types of symbols can differ in their level of *iconicity*, or the degree to which the symbol visually resembles its referent (Millikin, 1997; Ronski, Sevcik, Cheslock, & Barton, 2006). In general, it is thought that iconic systems are easier to learn and easier for communication partners who have not been taught the system to understand (Hetzroni, Quist, & Lloyd, 2002). However, Ronski and Sevcik (1996) and Ronski, Sevcik, Cheslock, and Barton (2006) discuss their System for Augmenting Language (SAL), an approach developed for use with school-aged clients with severe cognitive disabilities who had fewer than 10 spoken words, some intentional communication, and a history of many years of unsuccessful communication experiences. SAL differs from other AAC systems in that it uses abstract visual symbols, rather than pictures, to stand for words, and it employs a speech-generating device that "speaks" the word for each symbol selected by the client. Their research has shown that this computer-based form of alternative communication that employs visual symbols and voice output can increase not only communication but vocal production and intelligibility, as well, in older clients without spoken language. Still, children just introduced to an AAC system are commonly given a highly iconic one to start with. The disadvantage of iconic systems, though, is that they are somewhat limited in generativity, or the degree to which they can support the user in producing a full range of novel, original communicative messages.

FIGURE 3-5 Blissymbols. (Reprinted with permission from Millikin, C. [1997]. Symbol systems and vocabulary selection strategies. In S. Glennen and D. DeCoste [Eds.], *Handbook of AAC* [p. 120]. San Diego, CA: Singular.)

For this reason, we want, whenever we can, to move clients toward less iconicity in their AAC systems as their development and skill with the system proceed, with a written system as the ultimate goal. Daniel (2004) discussed additional considerations in moving students along a continuum of AAC devices. Figure 3-6 presents an outline of the varying levels of iconicity seen in several aided and unaided AAC symbol systems.

The second issue in choosing an AAC system concerns *interface*. Communication boards containing words, letters, pictures, or symbols are sometimes used. Clients can indicate what they want to point out with a finger, head stick, headlight, or other device. Portable computers that either type out or produce synthesized speech versions of client messages also are available. These can be activated in a variety of ways: with a finger; stick; headlight; or a switch operated by sucking and puffing, head tap, eye movements, or whatever motor abilities the client can muster. These devices allow the client to select the letter, word, symbol, or picture he or she wants from an array presented on the computer screen, either by direct selection or by scanning through a series from which the client chooses when a cursor gets to the desired item. Recently, programs such as Proloquo2go provide speech generation from pictures and symbols on consumer electronic devices such as smart phones and note pad computers. These platforms can be powerful in reducing stigma and making communication with the device user more appealing, especially for peers. (See Binger & Kent-Walsh, 2009; Glennen and DeCoste, 1997; and Miranda & Beukelman, 2006 for a more complete discussion.)

Augmentative communication use often begins with single message switch devices.

FIGURE 3-6 Symbol iconicity: Hierarchy of AAC symbols. (Adapted from Millikin, C. [1997]. Symbol systems and vocabulary selection strategies. In S. Glennen and D. DeCoste [Eds.], *Handbook of AAC* [p. 120]. San Diego, CA: Singular.)

The choice of a particular augmentative or alternative system is always a matter of experimentation to see what works best for a particular individual. The clinician working with a client who needs an augmentative or alternative system should give the client the opportunity to try the full range of devices that his or her abilities allow. Choice of a system should depend on the ease, accuracy, and efficiency with which the client can use the system, and these won't be obvious until the client gives several systems an extended try. Electronic systems with speech generation devices are available and often very useful, especially since it is known that voice output capacity not only increases vocalization and intelligibility, as Ronski and Sevcik (1996) and Ronski et al. (2006) showed, but also improves phonological awareness skills, which may help in the development of literacy (Foley, 1993; Millar, Light, & McNaughton, 2004). And systems that can use consumer electronic devices like smart phones, rather than dedicated devices, may be less stigmatizing and more inviting to peers. However, some clients may need to start with a simpler system.

Another important consideration in choosing an AAC system should be the client's communication partners. Parents, siblings, teachers, and whoever else interacts regularly with the child should be involved in this decision from the beginning and should also be part of the process of training for using the system. Remember that communication is a two-way street. The client won't be able to use the system effectively if the people in the environment are not able to comprehend the messages (if, for example, the child is signing to people who don't know Sign), or are uncomfortable with the particular system, or don't know how to enable the client to use it (Calculator, 1997b). Kent-Walsh and McNaughton (2005) discussed the importance of including training for communication partners (family, teachers, aides, peers) when implementing an AAC system for a client. They identified four interactive skills that research has supported as leading to increases in conversation participation, turn-taking skills, and the range of communicative functions expressed by the AAC user. These functions are listed in Box 3-10. They emphasized the importance of systematically describing, demonstrating, practicing, and providing feedback to partners in a structured, direct instructional program in order to

achieve positive changes in the partners' interactive use of the AAC system. When implementing an AAC system for a client, it will be important to include a carefully designed program for helping communication partners participate in the client's new communication modality.

Consequating Client Language

Once we have succeeded in getting the client to produce some communication, whether in the form of speech, Sign, or some other modality, our responsibility as clinicians—rather than ordinary interlocutors—is to provide the client with a consequence for the production. One type of consequence is what behaviorists call *reinforcement*. The intent of reinforcement is to increase the frequency of the behavior being reinforced. Reinforcement can be tangible, such as a raisin or a sticker given for correct imitation of a sentence, or it can be a token, such as plastic chips or hash marks on paper, that are accumulated to “buy” an object or activity the client likes. Reinforcement also can be social. Social reinforcement takes the form of praise or approbation (such as the dreaded “Good talking!”). These kinds of reinforcement that are outside of the interactive frame and do not contribute to the interaction itself are called *extrinsic reinforcements*.

Reinforcement also can be more *intrinsic* to the communication process. It can be a naturalistic social reward, such as the achievement of the intended goal of a child's request (the child says, “Want crayon” and is given one) or the control of the clinician's attention or actions through the client's language (the child says, “See!” and the clinician looks at what the child points out). All these consequences are reinforcement, though some are clearly more natural reinforcers than others. A behaviorist would accept any of these forms of reinforcement as a valid way to increase the frequency of the desired behaviors. A pragmatically oriented clinician, on the other hand, would only accept natural communicative consequences as an acceptable form of reinforcement.

A second kind of consequence we can provide is somewhat different from reinforcement. This kind of consequence is *feedback*. Unlike reinforcement, feedback is not intended to increase the frequency of the client's behavior. Instead, its intent is to give the client information about the communicative value or linguistic accuracy of an utterance. In addition, it often provides the child

BOX 3-10 Interactive Functions of Communication Partners that Increase Communication Opportunities for Clients Using AAC Systems

- Use extended pause time and expectant waiting to increase opportunity for client to take a conversational turn.
- Respond to all user attempts to communicate, whether with the device, or by means of vocalization, gesture, or gaze; treat behaviors with the AAC device as if they were communicative and respond even when user's intent is not entirely clear.
- Use open-ended questions to encourage more elaborated response from user.
- Model using the AAC system to communicate; accompany speech with indicating symbols on the user's device to show that the device is a means anyone can use for communication.

Social reinforcement can be used to consequate client language.

with a scaffold to a more acceptable production. We talked about many forms of feedback under the CC approaches. CC approaches generally consequence client language behavior with feedback rather than reinforcement, except when they use natural communicative consequences as reinforcement, as we saw earlier.

It is possible to use feedback in CD approaches also, though. Lee, Koenigsnecht, and Mulhern (1975), for example, provided a set of “interchange techniques” in their CD program, *Interactive Language Development Teaching*. A clinician can use these, too, as feedback to consequence an incorrect production. Some of these feedback techniques are given in [Box 3-7](#).

Gillam and Loeb (2010) identify both feedback and reinforcement as two of the essential ingredients in successful intervention outlined in [Box 3-9](#). They argue for providing *both* information about the accuracy of the response, as well as rewards, not only for correct responses but also for attending to tasks and maintaining desired behavior during intervention sessions.

Generalizing Language Gains

The goal of language intervention is not only to get the client to produce appropriate forms in response to our stimuli but also to get the child to use these forms in real interactions. Moving from use of communication in structured, formal situations to using the same forms and functions in real life is the process we call *generalization*. Traditionally, generalization is thought of as the last step in the intervention process, something we work toward after all other objectives have been met. But really, generalization ought to be incorporated into every intervention session, though not every activity, just as we advocated using more naturalistic activities for every goal, but not for every activity.

Although our hope is that generalization will just happen as a result of our intervention, we know that this is often not the case. As we saw when we talked about CD approaches to intervention, years of research have shown that children do not always generalize the forms learned in this manner to spontaneous conversations, even when high levels of accuracy are achieved in the structured setting. An argument that is commonly used for more naturalistic clinical approaches is that they are more likely to lead to generalization, since they are more similar to the other settings in which the targets will be used. But even when we use naturalistic approaches we cannot assume that the client will spontaneously generalize the language behaviors we train to people, places, and purposes outside the clinic.

So what do we do? If even a careful mix of structured CD and less formal hybrid and CC approaches does not guarantee that the client will spontaneously transfer learning, how can we achieve generalization? Costello (1983) and Smith (2001) argued that this could only be done by carefully planning generalization training within the context of the intervention program. Their guidelines for achieving this transfer of training will be summarized here.

First, Costello suggested that we use *many exemplars* of target forms and functions. This means that we should not stop training when the client is responding with high degrees of accuracy to a limited set of exemplars, such as a set of pictures. Nothing is wrong with using a limited set of stimuli in a repetitive CD format to elicit new forms from clients who use them very infrequently. Once this has been done, though, we cannot assume that the client will generalize the form’s use. We need to work toward that generalization by providing many different examples of how the form can be used, when it can be used, and who can use it in real conversations. And one or two real situations may not be enough. We may need to provide quite a few. If we are teaching a client to use “is (verb)-ing” to describe ongoing action, it may not be enough to have the

child use it to tell about making pudding. The child may have to tell about making a collage, a pizza, and a birthday card, too.

Another aspect of the multiple exemplars idea is the notion of *sequential modification*. Sequential modification happens when the intervention environment is extended from one place to another until spontaneous generalization to new environments occurs. For us it means that in addition to providing multiple exemplars of target forms, we should do so in multiple settings. These could include the client’s home, the classroom, outdoors, or in the cafeteria. How many different settings? Costello suggested that two or three are enough. This does not have to be an overly arduous or expensive process. One or two sessions in one or two alternate environments every few months of intervention may be adequate. For school-aged and adolescent clients this may suggest the “pull-out/sit in” model of service delivery, in which some sessions take place in the clinician’s office and some in the child’s classroom. For preschoolers, it may mean that now and then the clinician travels to the child’s home, day-care center, or preschool. This form of generalization training involves doing what the clinician normally does with the client in a different place.

Costello also suggested that we *make the treatment material similar to things used in the natural environment*. This may mean, for example, using classroom textbooks rather than specially designed materials in intervention for school-age children or using the storybooks read in the preschool class instead of commercial “speech therapy” materials.

Intermittent or delayed reinforcement is another important generalization tool. Costello warned that these schedules would probably not be effective in the early stages of training, when more consistent reinforcement is necessary to stabilize target productions. Once stabilization is achieved, though, extrinsic reinforcement should, as discussed earlier, be less and less frequent, and the use of natural contingencies should be increased. In this way the contingencies of training become more similar to those found in the natural environment.

Another one of Costello’s ideas for promoting generalization involves introducing *distracter items* into the intervention stimuli. The theory is that we should use some stimuli that are semantically relevant but not direct targets of intervention because this more closely resembles what happens in natural conversation. In other words, occasionally within a training sequence used to elicit particular language targets, the clinician should inject a relevant comment that will elicit a nontargeted response from the child.

These suggestions are important because children’s language use cannot be maintained in the natural environment if they cannot withstand the inconsistent, delayed, and indirect reinforcement contingencies that the natural environment provides. An additional way to guard against this danger is to attempt to increase the frequency of the child’s communication by targeting high rates of response within the initial phases of training and to provide multiple opportunities for the child to produce the same responses in hybrid and CC settings. Focused stimulation and script activities may be particularly useful in this regard. Increasing rates of production also may help the child to automatize production processes, freeing resources to be devoted to more complex levels of language formulation. In other words, practice makes perfect. Providing extended practice with new forms and functions may increase generalization and provide a scaffold to higher levels of language complexity.

Another strategy that may be useful in helping children to transfer learning is the use of *self-monitoring*. This requires

encouraging the child to become the internal “teacher” who constantly judges performance. If we can get clients into the habit of evaluating their own communicative effectiveness in the clinic setting, they are more likely to do so in other situations. Self-monitoring is particularly effective for clients at advanced language levels who have higher degrees of meta-linguistic and metacognitive ability than preschoolers. A client learning a particular communicative function, such as using questions to elicit information, can engage in a conversation with the clinician that is recorded via audiotape. The client can listen to the tape. The clinician can stop it after each client remark and ask, “Was that a good way to find out?” Roles can be switched and the client can make the same requests for self-monitoring to the clinician. During a third round of listening, clients can be prompted to ask the same question for each of their own utterances.

Even young children can do simple self-monitoring. They can begin by monitoring the clinician. Almost all children enjoy the opportunity to correct an adult’s “mistakes.” They can then be asked to make intentional mistakes themselves and let the clinician “guess” if they produced the target right or not, earning a point each time the clinician “discovers” an “error.” They also can be given self-monitoring prompts, like those suggested by Lee, Koenigsnecht, and Mulhern (1975), “Did you say that right?”

Another way we can increase children’s tendency to generalize language training is by encouraging them to take advantage of models in the environment. We can do this, first, by making imitation or use of a model in the intervention setting very rewarding. We accomplish this by praising and reinforcing clients for their efforts to imitate as well as for their production of specific forms. Second, we can provide the client with some very salient and appealing models. Hart (1981) suggested using peer models. Putting the client in a structured communication situation with a peer with the clinician available as a “troubleshooter” may be a helpful way to attain this end and effect generalization. Research on social skills training in autism spectrum disorders, for example, provides strong evidence of the efficacy of peer-mediated approaches (Ferraioli & Harris, 2011).

We’ve discussed a wide variety of techniques for encouraging clients to generalize the results of our intervention to real communication. The most important point to take away from this discussion is that generalization needs to be built consciously into our intervention programs. Using CD approaches will not ensure it. Using naturalistic approaches cannot guarantee it, either. The only way to be sure that our teaching generalizes to real conversation is to make a concerted effort to see that it does and then to evaluate the use of targets in natural settings, as we discussed in the assessment section. Hoping for generalization, or assuming it will happen, will not make it so.

The Context of Intervention

The context of intervention, according to McLean (1989), involves the physical and social settings in which the intervention takes place. Let’s look at some of the ways we can manipulate the context of intervention to achieve our objectives for the client.

Choosing the Nonlinguistic Stimuli

We’ve talked already about the importance of controlling the linguistic stimuli in intervention. In addition, though, we need to choose the nonlinguistic context of objects and events in which the intervention takes place. Let’s examine some of the choices we have available.

Types of Stimuli

Clinicians often use text, pictures, toys, and real objects as nonlinguistic stimuli in intervention. Pictures are popular choices because they are convenient and easy to obtain. For young children, though, pictures may not be a best first choice. They may contain too few central aspects of the referent. For example, an important thing to know about the meaning of the word “ball” is that balls roll. A picture of a ball may not convey this notion. Leonard (1975b) showed that children acquired certain syntactic forms more readily when given demonstrations of event referents for the sentences than when shown pictures. This is not to say that we should never use pictures, only that we should not use pictures exclusively. Furthermore, the younger the client, the more advantageous the use of objects and real events is going to be. Lahey (1988) pointed out that young children also seem to be more interested in moving objects than static ones and are most likely to talk about objects they act on themselves. For example, a toy with a button that a client pushes may be more interesting than one with a key that the clinician must operate for him. This suggests that successful intervention for young children includes allowing them to manipulate real objects and providing objects that do something interesting when they are manipulated, such as make a noise, move, fit onto something, light up, or play music. This approach will also increase the ingredient of active engagement, that we saw was one of the basic principles of successful intervention in [Box 3-9](#).

For older clients, though, pictures, particularly in the form of photographs, can be very engaging. Tarulli (1998) discussed a variety of uses of photography in intervention for school-aged children, most of which focus on linking the client’s personal experiences, as recorded in the photos, with language use. Examples include using photographs from class events as a basis for labeling, describing, and writing about the events or to compare and contrast experiences in which the child participated, such as a field trip to an aquarium, with those described in a nonfiction text, such as a book on marine life. The advent of digital photography on smartphones and other accessible devices makes collecting and printing pictures to use in intervention available to most clinicians and families.

What about pictures on a computer screen? Many software programs designed to provide computer-assisted language intervention use amusing pictures or moving images as either stimuli or reinforcement for child language behavior. These are often very entertaining for children. Many have lots of experience with computer or hand-held games from a very early age. Steiner and Larson (1991) pointed out that using a computer often can be very exciting for children because it allows them to “command the machine.” The danger in this is that the human-machine interaction may overshadow the interpersonal communication that is the goal of our intervention. When children enjoy computers and when programs are available that target goals identified in the client’s assessment, there is every reason to include them as part of the intervention program, so long as the clinician interacts with the child as he or she uses the machine. Cochran and Masterson (1995) report on several research studies that show clinician-mediated computer-based activities to be comparable in efficacy with more traditional approaches. They find no evidence, though, that children with speech and language problems show improvements in interactive communication as a result of independent computer use. This is true even of Fast ForWord (Scientific Learning Corporation, 2000), perhaps the most popular computer-assisted language development program as of this writing. Cohen et al. (2005), Fey, Finestack, Gajewski, Popescu, & Lewine (2010), and Given, Wasserman,

Chari, Beattie, and Eden (2008) compared results of Fast ForWord intervention with other computer-assisted intervention activities, as well as with traditional intervention. They found that children receiving several different kinds of intervention made gains, although there was no advantage for any computer-based method over regular speech-language therapy. Troia and Whitney (2003), in studying Fast ForWord, found that positive changes were seen in tested expressive language, but not in academic or social skills. Loeb, Stoke, and Fey (2001) also saw changes on expressive test scores following Fast ForWord training, but did not find that these translated to functional language use. A small study of children with autism, however (Hetzroni & Tannous, 2004), suggests that these children do show some improvement as a result of exposure to an interactive video game focused on social communication.

Cochran and Masterson (1995) discussed several uses to which computers can be put in clinical practice. One is as a context for treatment. In this use, the computer program or game functions as the topic of conversation. For example, an activity might involve using a graphics program, such as *Walt Disney Comic Strip Maker* (The Walt Disney Co., 1983), to create a greeting card, or a creative writing program, such as *Mystery at Pinecrest Manor* (Klug, 1983) or *Tiger's Tales* (Hermann, 1986), to generate a story. Here the computer serves as the shared context for structured conversation, much as a board game or craft activity can in more traditional activities. For school-age children and adolescents with language-learning disorders there is a wealth of educational software designed to teach mathematics, history, geography, and other topics. *Where in the World Is Carmen Sandiego?* (Bigham, Portwood, & Elliott, 1986) provides just one example. Since many students with language-learning disabilities have low levels of general information because they have difficulty acquiring new knowledge from language and print, these programs can often help to fill in the gaps in their knowledge base. They generally require reading skill, so the clinician can either read the text to the client or choose programs carefully to match the client's reading ability. Adolescents with language-learning disorders, for example, may benefit from educational software designed for elementary students. Content-related educational software also can give the clinician a base of information to be used to help clients work on, for example, discourse comprehension skills such as summarizing, getting the main idea, and paraphrasing. Lots of other materials can serve the

same function, though, including classroom texts, Internet sites, library books, newspapers and magazines, carefully chosen children's literature, and commercial instructional materials. The point is that computer software is useful if it motivates clients, but a skilled clinician can find many ways to motivate clients. Commercially available multimedia programs also can be adapted for use with children with language disorders, and numerous resources are available on the Internet, at sites such as www.communicationdisorders.com, to give just one example. But as Steiner and Larson (1991) pointed out, good clinical practice always integrates computer-based instruction with other activities. The computer is just one tool, which always needs to be supplemented with other kinds of communicative activities.

A second important use for computers for school-aged clients is word processing as a way to facilitate the development of written language skills. Cochran and Masterson (1995) emphasize the advantages of "talking" word processors, not only for motorically impaired students who use them as an alternative communication mode, but for speaking students as well. They argue that the auditory feedback provided by these programs helps writers develop a better sense of audience as well as identify grammatical errors. They cite research demonstrating that students given word processing opportunities improved in written language skills.

Some software (e.g., *Micro-LADS* [Wilson & Fox, 1983] and *Language Carnival* [Ertmer, 1986]) is specifically designed to teach language to children with disabilities. It often contains fixed vocabulary, uses too heavy a reinforcement schedule, or is very expensive when it is applicable to only a few children in the caseload. Programs designed for more general use, such as *Stickybear ABC* (Hefter, Worthington, Worthington, & Howe, 1982) or *The Factory* (Kosel & Fish, 1984), may be just as useful as more expensive software designed for children with language disorders and can be adapted for a variety of intervention goals. Coufal (2002) and Westby and Atencio (2002) provide additional discussion of these issues.

Timing

Besides deciding what the client needs as a referent for the linguistic signal, we also need to decide when the referent will appear. This simply means that we need to be careful about the timing of our nonlinguistic stimuli to be sure that they correspond appropriately to what is being said. This is sometimes not as simple as it sounds. Take past-tense forms, for example. To demonstrate an action referred to with a past-tense form, it is important to be sure that the action is completed before the speech act begins. We might throw a paper airplane across the room, then say to the client, "Tell me what I did." "You threw (or flew) the airplane," would be an appropriate response. But if we asked the question *while* throwing the paper airplane, our question would be inappropriate. We must plan our linguistic stimuli carefully to be sure that they elicit the target response appropriately, and the same is true of the timing of the stimuli in reference to the nonlinguistic context.

Service Delivery Models

There is one final aspect of the context of intervention. This refers to where, when, and with whom the intervention takes place. Traditionally we think of language intervention as taking place in a clinic room with a clinician providing therapy to a client or a small group for several 30- to 60-minute sessions each week. This model is often referred to as a *pull-out*, or *clinical*, form of service delivery. But language intervention can be delivered in a variety of ways. We'll discuss options briefly here and return to them in later

Computer-assisted language therapy is often popular with young clients.

chapters when we talk about which service delivery models are most appropriate for clients at different ages and developmental levels.

The Consultant Model

As we have said, the traditional answer to the question, “Who delivers language intervention?” is “the speech-language pathologist.” But an additional role for the SLP has evolved—that of consultant. In a consultant role, the speech-language pathologist still determines the intervention targets, procedures, and contexts. But instead of relating directly to the client, the SLP relates to another agent of intervention, giving that person information and a rationale for the intervention targets and more or less detailed instructions for the intervention procedures. The SLP also meets regularly with this individual to provide feedback on the intervention process, discuss problems that arise, and plan further intervention targets and activities. When acting in a consultant role, the SLP remains responsible for evaluating the client’s progress in the intervention program, for deciding when targets have been met, and for troubleshooting the intervention procedures and contexts to ensure that they are effective.

The alternative agents of intervention may be parents, classroom teachers, speech-language aides, or peers. Girolametto and Weitzman (2006) reviewed research showing that parents can be trained to use focused stimulation techniques that will result in positive changes in language form and content. Cole, Maddox, and Lim (2006) showed that interactive story book sharing techniques could be effectively implemented by parents and teachers to improve children’s language skills. Law, Garrett, and Nye (2004) reported few differences in the outcomes of language therapy for preschoolers when the intervention was delivered by clinicians or trained parents. Given these findings, it is likely that clinicians will find themselves frequently playing the role of consultant to parents or educators who will work directly to improve language skills in children with communication problems. It will be important for

clinicians not only to know how to deliver effective intervention themselves, but to have effective means of teaching these techniques to others. Girolametto and Weitzman (2006) provide some guidelines, and more will be discussed in Chapters 6, 7, and 9.

Aides are used frequently in a variety of settings, especially when SLP shortages make hiring qualified personnel difficult. McCready (2007), however, emphasizes that the aide’s role is to assist, not replace the SLP, and it is the SLP’s role to plan, observe, monitor, review, and analyze the work of the aide, as well as to guide the aide’s learning by making time to discuss and integrate the aide’s experiences. Table 3-3 summarizes these roles.

Peers of the client also can be important agents of intervention. Paul (2003a) reviewed literature that suggests peers may be the most effective agents for teaching social communication skills to children with primary deficits in the area of pragmatics. When training peers it will, again, be important to have effective ways of teaching them how to support and expand clients’ communication attempts. Several programs for peer training are discussed in Chapters 9 and 14.

The Language-Based Classroom Model

Here the clinician is the classroom teacher for a group of students with language disorders. Mainstream students also may be members of the class, although the focus is on intervention for the group with disorders. Language-based classrooms at the preschool level resemble traditional preschool programs. Many of the themes and activities resemble those used in mainstream preschools. The main difference is that SLPs in these settings use their expertise in language development and intervention to maximize the students’ opportunities to attend to and practice oral language. What distinguishes them from the clinical model is that the SLP provides a continuous form of intervention embedded within a context of day-to-day activities.

For school-age clients, language-based classroom instruction may comprise either the entire school day or part of the day, depending on

TABLE 3-3 Reciprocal Roles of SLPs and SLP Aides*

SLP Role	SLP Aide Role
Select and assign clients to SLP aide (SLPA).	
Determine nature of supervision appropriate for SLPA; interact with SLPA in planning and implementing supervisory conferences; establish and maintain effective professional relationship with SLPA.	Participate in supervisory process.
Establish and maintain system of accountability and documentation for SLPA.	Assist with informal documentation, as directed by SLP.
Demonstrate for and participate with SLPA in the clinical process.	Support the SLP in research, in-service training, and public information programs.
Select screening instruments; interpret screening results.	Assist with screenings.
Conduct assessments.	Assist SLP during assessments.
Develop individualized treatment plans.	Follow treatment plans developed by SLP; document client performance by tallying data and preparing charts and records.
Provide feedback to SLPA on clinical skills.	Collect data for monitoring quality improvement.
Assist SLP with developing clinical, oral, and written language skills, preparing and presenting clinical materials and treatment environments; model professional conduct.	Assist SLP with clerical activities such as preparing materials and scheduling; assist with departmental operations.
Train SLPA to maintain clinical records, check and maintain equipment, and observe universal precautions.	Perform checks and maintenance of equipment.
Share information on ethical, legal, reimbursement, and regulatory practices.	Exhibit compliance with regulations, reimbursement requirements, ethical standards, and SLPA job responsibilities.

the severity of the student's needs. This organization places children identified as having special needs in a "resource room" with the SLP as the classroom teacher. The SLP provides instruction for each client, according to his or her Individual Educational Plan (IEP), and also organizes activities that focus on oral language skills for the group. Many students in this setting also spend part of their school day with a regular teacher in a mainstream classroom.

For adolescents with language disorders, the language-based classroom model often takes the form of one of the student's classes. When the mainstream students go to English for a 50-minute period, for example, the student with a language-learning disorder may go instead to a language classroom taught by an SLP. The organization of this classroom is similar to that of the resource room at the elementary level. But because the students usually spend less time there, perhaps one period a day for one or two marking periods of the school year, instruction is more concentrated. Theme-based and curriculum-based approaches are often used to help the students develop not only oral language abilities, but also study skills, thinking skills, and the ability to deal more proficiently with written forms of language.

Collaborative Models

Midway between the consultant model and the language-based classroom model, in terms of intensity of client contact, is the collaborative model. The SLP works with one or more students who have been identified as having a language disorder, but does so in the mainstream classroom in collaboration with the regular teacher. Instead of seeing the client in a clinic or pull-out setting, the clinician delivers the intervention mandated in the IEP in the context of the regular classroom. This model, too, can be implemented at any developmental level, from preschool through adolescence.

The collaborative model requires consultation and cooperation with the classroom teacher. The SLP and teacher must meet together to decide what classroom material will fit in with the goals identified on the client's IEP and how the SLP can either develop activities in line with those themes or use the regular teacher's normal classroom activities to work toward IEP goals. The SLP then plans the specific activities to be used and works within the classroom alongside the regular teacher. The SLP focuses primarily on the children identified as having a language disorder, whereas the regular teacher focuses on the other students. Ehren (2000a,b, 2007), Michaels and Ferrara (2005), and Prelock

(2000) provide some additional guidelines in implementing collaborative practice. Here's an example of how a collaborative activity might work.

Suppose George and Martha are students identified as having language disorders. Both are in Ms. Marshal's fourth-grade class. One of the goals identified on George's IEP is producing complex sentences. Martha has production and understanding of narratives as an IEP goal. Mr. Taylor, the SLP, consults with Ms. Marshal about doing some in-class activities to work toward these goals. They decide together that Ms. Marshal's literature unit on fantasy novels might be a good context for the intervention activity. The class has been reading children's books that tell fantasy stories. So Mr. Taylor decides to have the class write a fantasy story of their own in small, cooperative learning groups. He puts George and Martha in separate groups and arranges with Ms. Marshal that he will supervise these two groups while she supervises the other three.

Mr. Taylor introduces the lesson and has the class talk about the differences between fantasy and reality, give examples of fantasy books they've read, and generate some ideas for fantasy stories about magical animals. He then tells the students that each group is to work together to write a fantasy story, but first he wants to talk about what makes a good story. He writes two short choppy sentences on the board (such as, "The dragon was fierce. The dragon breathed fire.") and asks students to judge whether these tell a story well. Then he asks for suggestions from the class about how to better convey these thoughts, by combining them into one sentence. After letting several mainstream students model this process, he asks George to do one. Then he asks the class to think about what parts their story should have. He can ask them to recall some of the fantasy stories they've read and identify parts, such as main character, setting, a problem that gets the story going, and so on. He can have several mainstream students identify these parts in books they have read. Then he can ask Martha to do so.

Next he tells the class that each group is to write a short fantasy story about a magical animal. He reminds them to make their sentences more informative by sometimes combining two ideas into one. He reminds them about the parts that a good story should have. Then he and Ms. Marshal work with their cooperative learning groups. Mr. Taylor is careful to be sure that George and Martha are fully involved in their respective groups and have opportunities to contribute. He reminds them about complex sentences and narrative structure as he "troubleshoots" for them within the activity. This project may take more than one collaborative classroom session to complete. When the project is finished, the groups may illustrate, display, and share their stories.

Collaborative intervention does not need to be an all-or-nothing affair. Some clinicians use a "pull-out/sit-in" version. In this approach, some intervention is provided in a pull-out or clinical format, perhaps once or twice a week. Additional intervention, perhaps once a week, is delivered collaboratively in the student's classroom.

All the service delivery models we've discussed—clinical, consultative, language-based classroom, and collaborative—are valid contexts for language intervention. The choice depends on the needs of our clients and the clinician's relations with other professionals who work with them. Cirrin et al. (2010) reported data showing that classroom-based direct services are at least as effective as pull-out intervention for many intervention goals. We'll talk more about criteria for making these choices when discussing intervention for different developmental levels. The

Collaborative planning is needed for clients in integrated settings.

important thing for now is to be aware of the range of service delivery options that are available and not think of ourselves as being limited to one option to the exclusion of others.

EVALUATING INTERVENTION OUTCOMES

We've talked about the importance of planning each aspect of language intervention: the selection of objectives, the choice of procedures, and determination of contexts. But we have an additional responsibility: to demonstrate that we have not wasted the client's time; that we have, in fact, achieved the goals that we set for the intervention. This responsibility is known as *accountability*. We are accountable to the client, and to whoever paid for our services, for making a significant change in language behavior. Furthermore, we should be able to show that the changes we made would not have happened if our intervention had not taken place. Let's talk about how we can fulfill these responsibilities.

Termination Criteria

One way to demonstrate that intervention objectives have been met is to specify ahead of time what criterion we will use to decide that a goal has been achieved. This specification is called the *termination criterion*. ASHA (2004e) has proposed a list of criteria for terminating services. These are summarized in Box 3-11.

The termination criterion for individual objectives, as opposed to termination from an intervention program, is simply the level of use of a targeted structure that the client must achieve for the structure to be considered learned. In behaviorist intervention formats, this criterion is usually set quite high, at 80% to 90% correct usages. However, usage is measured within the structured intervention context. Lee, Koenigsnecht, and Mulhern (1975) have argued that termination criteria should be set lower, at 50%, but be measured in natural contexts such as spontaneous conversation. It seems to us that to claim we have truly changed language behavior, we have an obligation to show that the client does use the targeted forms in natural, spontaneous speech. Furthermore, we know that once children use forms a majority of the time in spontaneous speech, they are very likely to progress toward consistent correct usage on their own without intervention. So a criterion of 50% correct usage

in spontaneous speech seems likely to be a responsible terminal objective for any particular intervention goal.

But how will we know when to take that spontaneous speech sample to determine whether 50% correct usage is achieved? Here we would want to see high (80% to 90% correct) levels of usage in the structured intervention setting before we would expect the child to use the forms spontaneously. Therefore, some charting of progress in structured intervention formats is an important part of the intervention program. A simple form such as the one in Figure 3-7 can be used to track performance in structured activities. As we discussed in Chapter 2, it is not necessary to chart every activity, but only to take samples periodically throughout the structured portion of the intervention program. Furthermore, we know that high degrees of accuracy in CD formats will not guarantee that usage will generalize to spontaneous speech. So once we get those high levels of use in structured activities, we should use the generalization techniques we discussed, if we have not done so already. We also would be wise to give the client some opportunities to use the forms in hybrid and other more naturalistic intervention formats. When all these have been accomplished—high levels of accuracy in structured formats; provision of activities designed to promote generalization; and use of hybrid, CC, or naturalistically modified CD intervention activities—then we should monitor the use of target forms in unstructured conversation, using speech sampling or other criterion-referenced techniques.

If correct use of the forms in this context exceeds 50%, we suggest discontinuing direct intervention for that target. The target form should be monitored every few months in spontaneous speech, though, to see that its correct usage is increasing. If not, it can be returned to the intervention program. If the target form or function is not used correctly a majority of the time in spontaneous speech, even if the client is very successful in producing it in the structured context, more generalization training and naturalistic activities are needed to help the client make the transition to spontaneous usage. By using a termination criterion that requires use of intervention targets in real communication, we can be sure of fulfilling our obligation to demonstrate meaningful change in language behavior.

Evaluating the Effectiveness of Intervention

The second aspect of accountability concerns our obligation to make changes that would not happen without our intervention, as ethical practice requires (American Speech-Language and Hearing Association, 2010a). There are a variety of ways to evaluate the efficacy of intervention (see Dollaghan, 2003, 2004; Fey & Justice, 2007; McReynolds & Kearns, 1982; Ochsner, 2003, for discussions) including using single-subject research designs, in which each client serves as his or her own control. Fey (1986) argued that the most appropriate of these, for clinical purposes, is the *multiple-baseline* design. Multiple-baseline designs give us the opportunity to show that the behaviors we targeted in intervention improved more than other language behaviors that were not subjected to intervention. By demonstrating this facilitative effect of intervention, we can ensure that the time and money spent on intervention were worthwhile.

The procedures for conducting a multiple-baseline single-subject research design are schematized in Figure 3-8. The first step in implementing a multiple-baseline design to study the effects of intervention

BOX 3-11 Discharge Criteria

Intervention may be terminated if one or more of the following conditions are met:

1. Communication is now within normal limits.
2. All goals and objectives or intervention have been met.
3. The client's communication is comparable to those of others of the same age, sex, and ethnic and cultural backgrounds.
4. The individual's speech or language skills no longer adversely affect social, emotional, or educational status.
5. The individual uses an AAC system and has achieved optimal communication across partners and setting.
6. The client has attained the desired level of communication skills.

is to identify several intervention objectives, based on assessment data. Using some of the other criteria we discussed earlier, certain of these objectives will be chosen as targets of the intervention program. Others will not be chosen, perhaps because they are not considered high in communicative effectiveness, because they require phonological skills the client does not yet have, or because we feel they are low in teachability. The goals that were not chosen could be considered *control goals*.

When choosing control goals, we need to be careful to choose language behaviors different enough from the targeted goals so that response generalization is unlikely. Goals that are similar in form to the target goals can be chosen as *generalization goals*. These would be tracked along with the target and control goals to determine whether training is generalizing, as expected, to these similar behaviors. If, for example, “is (verb)ing” were the target, we would probably not want to choose copula “be” as the control goal, since

Rights were not granted to include this figure in electronic media.

FIGURE 3-8 The proposed steps in a multiple-baseline intervention design. (Redrawn with permission from Fey, M. [1986]. *Language intervention with young children* [p. 110]. San Diego, CA: College-Hill.)

it is quite likely that some learning from the “is (verb)ing” intervention program might generalize to copula use. Instead, we would designate copula “be” as a generalization goal. We might choose to use the auxiliary “will” as a control goal.

The second step in the multiple-baseline procedure is to gather baseline data on the target, generalization, and control goals. Elicited production procedures, such as the ones we discussed in Chapter 2, can be used to compute a percentage of usage in obligatory contexts for both target and control forms. It is important to establish a stable baseline for each form so we know that the baseline is a reliable reflection of the child’s ordinary use of the form. Baseline measures may be taken two to three times during the course of a few sessions, and percentage of usage may be averaged to achieve this stability.

The next step is to institute intervention for the target, but not the control or generalization goals, using all the principles of intervention that we have discussed. Although multiple-baseline designs are often used in applied behavior analysis, Fey (1986) pointed out that this fact in no way restricts us to CD intervention programs. We can make use of all the intervention approaches we have talked about when we implement multiple-baseline studies. Intervention is continued until our termination criterion for the target goal is met, including both high levels of correct use in structured formats and use of the targets in spontaneous conversation.

We would then evaluate the child’s use of the target and control goals. We can use the same elicited production tasks we used in the baseline studies, as long as they are not exactly the same as what we did in the intervention program. If use of the target and generalization goals shows a significant increase over the baseline, whereas use of the control goal remains unchanged, then we have demonstrated that our intervention was what made the difference in the client’s use of the target form. If we graphed the data from

such a study, it could resemble the graph displayed in Figure 3-9. We might then choose to go on and target the control goal for intervention as well.

Finally, we need to remember that meeting goals in a structured setting is not our ultimate aim. Our real objective is improved functional communication, what Kovarsky, Culatta, Franklin, and Theodore (2001) called “communicative participation.” Before deciding that a goal has been reached, we need to demonstrate that the goal has been incorporated into the child’s functional communicative repertoire. ASHA has developed functional communication measures (FCMs) for children, which are listed in Appendix 3-1. Jacoby, Lee, Kummer, Levin, and Creaghead (2002) showed that it was possible to document improvement in intervention using these FCMs, such that a majority of children (76.5%) improved by at least one FCM level following 20 hours or more of therapy. So we can identify a child’s pretreatment FCM and use this as a baseline for determining whether and to what extent functional changes have occurred in children’s communication following intervention. To determine these kinds of functional changes, Olswang, Coggins, and Timler (2001) suggested that communicative behaviors be assessed in a core set of salient contexts. These contexts include role-playing tasks, narrative tasks, structured peer interactions, and natural observation in real settings. Although we may not always sample every goal in every one of these contexts to establish its level of functional use, we do need to demonstrate that each communicative behavior we teach has become functional for the child in real social situations before claiming “effectiveness.” Table 3-4 provides some examples of Olswang et al.’s advice.

Determining Responsiveness to Intervention

One additional concept that has recently become of interest in the evaluation of treatment outcomes is the idea of measuring responsiveness to intervention (RTI) as an assessment technique. Gillam and Justice (2010), Graner, Faggella-Luby, and Fritschmann (2005), and Mellard, McKnight, & Woods (2009) discussed this concept as an emerging method of determining whether children qualify for special educational services. RTI approaches are designed to overcome the problem of identifying children with language and learning disorders based on a discrepancy, for example, between verbal and nonverbal test scores. We’ve already discussed the issues with this kind of identification for children with language disorders in Chapter 1, and the same problem occurs in identifying school children with learning disabilities (Graner et al., 2005; Justice, 2006), as well as preschoolers at risk for reading failure (Justice, 2005). In addition, children from poor and minority backgrounds often under-achieve in school and are frequently placed inappropriately in special education (Moore-Brown, Montgomery, Bielinski, & Shubin, 2005). RTI provides one possible solution to these problems. Using RTI, children are exposed to a series of levels of instruction, which Ehren and Nelson (2005), Fletcher and Vaughn (2009), and Troia (2005) defined as follows:

Tier I: classroom instruction for all children that is evidence-based, with frequent progress monitoring implemented by classroom teachers with adaptations provided by the SLP for children at risk. Progress is monitored by regular in-class evaluation. Children who show difficulties in learning at this level are given Tier II instruction.

Tier II: targeted, short-term research-based instruction designed to address weaknesses in children who struggle with language and literacy, as identified through progress monitoring; this

Rights were not granted to include this figure in electronic media.

FIGURE 3-9 Multiple-baseline study data. (Reprinted from Fey, M. [1986]. *Language intervention with young children* [p. 110]. San Diego, CA: College-Hill.)

intervention supplements regular instruction, is delivered in small groups by paraprofessionals or volunteers in consultation with the SLP and special educators; monitoring continues. Children who continue to struggle with language and learning at this level are given Tier III instruction.

Tier III: students who continue to struggle in Tier II instruction are considered in need of intensive, therapeutic intervention; SLP collaborates to determine this eligibility by evaluating response to Tier I and II instruction, and provides specialized language and literacy intervention in collaboration with others

using an individualized instructional plan once identification of special educational need is made.

The SLP has several roles to play in the RTI process. SLPs can consult with teachers and educate staff about how language influences all aspects of school performance, the identification of evidence-based practices in reading, writing, and spelling instruction, and the need for language-facilitating approaches in all areas of the curriculum. For Tier II instruction, SLPs can help to select or design the procedures to be implemented in small group instruction, such as the provision of phonological awareness training for

TABLE 3-4 Tasks for Documenting Functional Use of Communicative Goal Behaviors

Contexts	Example Goal	Example Activity
Role-playing	Negative sentences forms	"Let's imagine you're shopping for a pair of shoes, and the clerk is trying to sell you a pair you don't like. I'm the clerk. Act out what you would say to tell him why you don't want these shoes."
Narrative	Use of articles (<i>a, an, the</i>)	"Tell me about your class trip to the fast food restaurant. Tell me about the equipment you saw that they use when they make food there."
Structured peer interaction	Use of polite forms	"I'm going to give you and Aisha some toys to play with. Some are for you and some are for Aisha. If you want to use each other's toys, you have to ask nicely."
Natural setting observation	Use of quantity terms (<i>more, less, all, etc</i>)	Observe student during math lesson in which teacher gives instructions using quantity terms ("What's one more than two?")

Adapted from Olswang, L., Coggins, T. & Timler, G. (2001). Outcome measures for school-age children with social communication problems. *Topics in Language Disorders*, 22(1), 50-73.

young children or the use of morphological and "word study" approaches to spelling for older children (see Chapters 9, 12, and 14), and can train paraprofessionals and volunteers to deliver them. SLPs may provide, or collaborate in providing, Tier III instruction for children identified through the RTI process as having special educational needs. But perhaps the most important role that SLPs play in this process is through our knowledge and experience in evaluating treatment outcomes, since ongoing monitoring is a central element of RTI. Just as we've talked about evaluating the outcomes of our own intervention, we can use the same techniques—including determining termination or outcome criteria, tracking individual behaviors, developing nonstandard assessments including functional, dynamic, and curriculum-based methods, and using single subject design procedures—to determine whether the Tier I and II instruction has accomplished its goals. In this way, our expertise not only in language and literacy, but in evaluation methods that can contribute to the team's ability to use RTI to identify children at risk and work toward preventing school failure.

You may be feeling that, with all the thought and work involved in planning an intervention program, maybe trying to evaluate it, too, is just too much to expect. While we can understand that feeling, we must caution against giving in to it. The respect that we can command as professionals and as a profession rests to a large degree on our ability to prove that we make a difference. Because we don't usually cure our clients, but rather facilitate their language development, the fruits of our labor are not always easy to see. The client's continuing deficits may overshadow them, or they may not seem very different from maturational change. Because our results can sometimes seem invisible and because it really is important to document that we are making ethical use of time and resources, it is incumbent upon our profession to fulfill our obligation to be accountable. Only by doing so can we earn the respect we deserve and be in a strong position to advocate for the importance of the services we provide to our clients.

PREVENTION OF LANGUAGE DISORDERS IN CHILDREN

We've talked for a long while now about ways to change communication disorders. But any humane and responsible person would like to work toward preventing the devastating effects of these disorders by eliminating their root causes and thereby inhibiting the disorders from ever occurring. Why should prevention be our concern? Are we not speech-language pathologists, people who

diagnose and treat disorders of language learning? Isn't remediation our business? Certainly it is. In all areas of health care, though, including our own (ASHA, 2004d; Marge, 1993; Executive Order Establishing the National Prevention, Health Promotion, and Public Health Council, the White House, June 2010 [www.whitehouse.gov/the-press-office/2010/06/01/eo-13546-national-prevention-health-promotion-and-public-health]), there is a national trend away from exclusive attention to rehabilitation and toward prevention efforts. This trend arises partly from our knowledge of the enormous cost of rehabilitation and the burden it places on all levels of the economy. In 2003, the Centers for Disease Control estimated that preventing even one case of intellectual disability can result in long-term savings of more than \$1 million, and the figure would be even higher today. The U.S. Public Health Service (PHS), in its Healthy People 2020: National Health Promotion and Disease Prevention Objectives (Department of Health and Human Services, www.healthypeople.gov/2020/default.aspx, accessed 4/3/11), has established national goals for improving health, reducing risk factors, providing screening and early identification resources, and increasing public awareness and information about health and the prevention of disease; disability is one of their focus areas. ASHA has worked with the PHS to develop objectives for reducing the incidence of communication disorders. As responsible health professionals, we have an obligation to contribute to these efforts.

There is another reason, too, why SLPs would be concerned about preventing communication disorders. As the professionals who deal day to day with these problems, we know the suffering they bring to our clients and their families. We know how a parent of a preschooler with little speech feels when she sees her child made fun of or left out by other children because the child cannot talk. We know how a language-impaired fourth grader who has trouble understanding the teacher feels when he fails yet another spelling test, even after he studied hard for it. We know how a teenager with a language-learning disability feels when he can't get a date for a school dance because his pragmatic skills are so poor. We know how a high-functioning adolescent with autism feels when he sees his classmates "rapping" and using slang that he cannot master or understand and when they giggle at his attempts to join them. We know because we try every day to help our clients overcome these problems. But how much better it would be, from a purely human standpoint, if they never happened in the first place! Although our job is the remediation of language disorders, our concern is for the welfare of our children and their families. It is this concern and our knowledge of the central role of communication in human development that

urges us to work toward not only treating but also preventing disorders of language learning. This has, in fact, happened in some cases. The last major epidemic of rubella was in 1965. Since the introduction of inoculation against this disease, new cases of profound hearing impairment caused by rubella are very rare, despite the fact that rubella was one of the most common causes of acquired deafness in children before the availability of the vaccine. But this ideal situation, in which we eliminate the cause of a disorder, is not always achievable. Sometimes prevention has to occur in a more modest way. Epidemiologists look at prevention as happening at three levels. Definitions of each of these levels of prevention, as discussed by the Committee on Prevention of Speech, Language, and Hearing Problems of the American Speech-Language and Hearing Association (ASHA, 1991, 2004d), are found in Table 3-5.

Primary Prevention and the Speech-Language Pathologist

ASHA (2005b) and Marge (1993) identified several primary prevention strategies that can be applied to disabilities that lead to communicative disorders. They include proper health and medical care, including immunizations and prenatal care; public education; genetic counseling; mass screening and early identification; environmental quality control; governmental action; and the elimination of poverty. Donahue-Kilburg (1993) argued that wellness promotion is another primary prevention tactic in which SLPs can engage. This approach involves optimizing psychological, physical, and behavioral well-being to increase resistance to disease or disorder. Donahue-Kilburg suggested that family-centered early intervention programs are ideal settings in which to promote wellness as a means of preventing communication disorders. Wellness promotion in these settings might involve encouraging good maternal nutrition and prenatal care to promote optimal fetal growth, helping parents of premature babies to become aware of infant states and receptive capacities so that they can maximize interaction, and working to help pregnant women avoid drug and alcohol use during pregnancy. Table 3-6 lists some suggestions for primary prevention activities that SLPs employed in a variety of settings can initiate. “May Is Better Hearing and Speech Month,” sponsored by ASHA, is always a good opportunity to introduce efforts like these.

When primary prevention is accomplished, the incidence of a disorder is reduced. *Incidence* is defined as “the rate of new

occurrences of a condition in a population free of the disorder within a specified time period” (ASHA, 2005b). In other words, incidence refers to the number of new cases of a disorder that appear. For example, Down syndrome has an incidence of 1 in every 800 live births. This means that for every 800 babies born, 1, on average, has Down syndrome. This one baby out of 800 who is born with Down syndrome contributes to the total number of individuals in the population who have this condition. Epidemiologists have another term for this total: prevalence. *Prevalence* is defined as “the total rate or proportion of cases in a population at, or during, a specified period of time” (ASHA, 2005b). For example, the prevalence of learning disabilities is thought to be 5% to 10% of school-aged children. This means that at any given time, about 10% of a population of school-aged children will be affected by this disorder. Primary prevention is aimed at reducing the incidence, and thereby decreasing the prevalence, of disorders.

The Speech-Language Pathologist’s Role in Secondary and Tertiary Prevention

Unfortunately we will never be able to prevent all disorders. In some cases, such as specific language disorders, we do not know the cause and so cannot ward off its effect. In other cases, in this imperfect world, primary prevention efforts will fall short of their goals. When this happens, we must fall back on secondary and tertiary prevention to minimize handicapping effects. SLPs can and should be active participants in secondary prevention, including early identification and treatment efforts, as well as in research programs to identify risk factors and preventive intervention methods. The advent of mandatory newborn hearing screening, as well as preschool and kindergarten speech/language screening programs are good examples of secondary prevention.

Then, too, old-fashioned tertiary prevention, or rehabilitation, will always be needed. Some children will “fall through the cracks” of even the most aggressive screening program and will turn up with problems in communication that need to be addressed by attempting to reduce the already-present disability. Some will need ongoing support as their disability persists throughout development. But this traditional role of the SLP, regardless of its clear importance and centrality to our mission, is no longer sufficient. To be the kind of professionals we all strive to be, who serve not only our individual clients but their families and communities, we need to expand our conception of what being an SLP means. It means not only picking up the pieces after disabilities strike but also working toward preventing them.

TABLE 3-5 Levels of Prevention as Defined By ASHA

Level	Description	Example
Primary prevention	The elimination or inhibition of the onset and development of a disorder by altering susceptibility or reducing exposure for susceptible persons.	Inoculation to prevent rubella.
Secondary prevention	Early detection and treatment are used to eliminate the disorders or retard its progress, thereby preventing further complications.	Newborn hearing screening to detect hearing loss and provide early amplification or cochlear implantation.
Tertiary prevention	Intervention is used to reduce a disability by attempting to restore effective functioning.	Providing rehabilitation and special educational services to a child with Down syndrome.

TABLE 3-6 Primary Prevention Activities in Various Employment Settings

Setting	Suggested Activity
Preschool or early invention program	Work with health officials to set up a low-cost on-site inoculation clinic. Set up a "Parenting" class to help parents deal with issues of discipline and prevent child abuse. Provide contraceptive and family-planning services to teens who have had one child, to prevent a subsequent pregnancy before the mother finishes school. Display poster, hold short education session to discuss dangers to fetuses of drugs, alcohol, and smoking for mothers who may become or are already pregnant again. Make arrangements with local health-care agencies to refer mothers for free or low-cost prenatal care if they become pregnant again.
Elementary School	Set up a "health education" class, using a curriculum such as "Smooth Sailing into Next Generation" (Plumridge & Hylton, 1987) to educate parents about family planning and preventing birth defects in future children. Work with health officials to set up a low-cost on-site inoculation clinic. Set up a "parenting" class to help parents deal with issues of discipline and prevent child abuse. Make arrangements with local health care agencies to refer mothers for free or low-cost prenatal care if they become pregnant again. Set up assembly programs with local police agencies to talk to students about seat-belt and helmet use. Send home a calendar on which each students is to mark the days on which everyone in the family used a seat belt in the car or on which every child in the family wore a bike helmet. Students who achieve a given number of days of use win a prize or have names posted on a bulletin board. Collaborate with drug and alcohol educational programs by "guest lecturing" to students about the dangers these substance pose. Hold an essay or drawing contest, "How I Will Get My Family to Use Seat Belts and Helmets." Display winning entries in the school newspapers with an interview with winners about how they convinced others to take these precautions.
Middle and high school	Hold an essay or drawing contest on "How I will Get My Family to Use Seat Belts and Helmets." Display winning entries in the school newspapers with an interview with winners about how they convinced others to take these precautions. Set up assembly programs with local police agencies to talk to students about seat-belt and helmet use. Collaborate with drug and alcohol educational programs by "guest lecturing" to students about the dangers these substance pose for unborn children. Work with health teacher to initiate a curriculum module such as "Smooth Sailing into Next Generation" (Plumridge & Hylton, 1987), to educate students about family planning, contraception, avoiding early sexual activity, and preventing birth defects in future children. Work with health teachers to initiate a curriculum module on parenting, discipline, and preventing child abuse. Set up a language stimulation class for teen mothers to help them learn techniques for encouraging language development.
Hospital or clinic	Arrange with obstetrics section for low-cost prenatal care for mothers of children on caseload, if they should become pregnant again. Develop referral network for getting families in touch with parenting classes, family-planning programs. Work with health educator and public relations office to offer classes in language development and preventing birth defects to families in the community. Encourage agency to mount public information campaigns to address drug abuse, child abuse, and seat-belt use.
Private practice	Offer parenting classes as part of your practice; include family planning and prevention of birth defects, using a curriculum such as "Smooth Sailing into the Next Generation" (Plumridge & Hylton, 1987), as well as methods of discipline and language stimulation techniques. Work with local pediatric practices to provide inoculations for clients who are lacking them. Offer to contract with local high schools to work with teen parents on a language-stimulation module within an existing parenting class, or on preventing pregnancy and birth defects in an existing health class. Offer low-cost speech and hearing screenings at community events that focus on children, such as toy "expos," etc. Involve practice in local public education campaigns regarding drug abuse, child abuse, seatbelt and helmet use, and similar issues.

CONCLUSIONS

Planning and evaluating language intervention requires us to make a series of decisions. We need to decide on the overall purpose of the program, the specific long-term and short-term goals, the procedures we will use to achieve these goals, the evidence

available to support the use of these procedures, the context in which the intervention will take place, and how we will demonstrate that we have made a real difference in the client's communication. What we have tried to do in this chapter is give you a broad overview of the range of options we have for making these decisions. We have tried to suggest that as clinicians we do not

need to pick just one approach, orientation, or style of intervention. We do not have to identify ourselves as behaviorists, milieu therapists, or pragmaticists; or as classroom teachers, consultants, or parent trainers. What we can strive for, instead, is access to the fullest possible set of tools for improving communication. We can then choose the right tool for the job of improving the communication skills of each individual client in our charge. We can work, too, toward preventing communication disorders by engaging in activities to promote communicative wellness and community education. We who know the high cost of these disorders, in both fiscal and human terms, should be among those most motivated to work for their prevention.

STUDY GUIDE

- I. The Purpose of Intervention
 - A. What are the three basic purposes of intervention? Give an example of a client for whom each would be used.
 - B. What are three ways that intervention can change language behavior?
- II. Developing Intervention Plans
 - A. Discuss the difference between short- and long-term goals.
 - B. Define and give examples of the *zone of proximal development*.
 - C. What criteria are used to decide which goals identified in the assessment will be targeted in the intervention program?
 - D. Name the three basic approaches to intervention discussed in this chapter. Give an example activity for teaching “is (verb)ing” as it might be done in each approach.
 - E. Why is it suggested that intervention focus on selecting production as a target response rather than comprehension?
 - F. Discuss the role of perceptual salience and pragmatic appropriateness in determining the linguistic stimuli to be used in intervention.
- G. What is meant by the *continuum of naturalness* in intervention? Give examples of three activities and settings at different points along this continuum.
- H. Discuss the considerations involved in determining the modality of language for the client to use.
 - I. Describe and give examples of both extrinsic and intrinsic reinforcement.
 - J. Describe five activities for promoting generalization of plural forms.
 - K. Discuss the uses of computers in language intervention.
 - L. Name and define the four models of contexts for language intervention. Give situations in which each one would be the best choice for teaching use of the conjunctions “because,” “unless,” and “although.”
- M. Discuss the criteria you would use for evaluating a new technique to decide whether it is evidence-based.
- N. Discuss the essential ingredients in successful intervention, and give examples of incorporating each into a therapy program.
- III. Evaluating Intervention Outcomes
 - A. Define *termination criteria*, and discuss the guidelines suggested in the text.
 - B. Describe how to implement a multiple-baseline study of language intervention.
 - C. Why is it important to evaluate the effectiveness of intervention?
 - D. How can functional use of communication be evaluated?
- IV. Prevention of Language Disorders in Children
 - A. Define and discuss levels of prevention identified by ASHA.
 - B. Compare and contrast the meaning of the terms *incidence* and *prevalence*.
 - C. What primary prevention strategies are appropriate for disorders of genetic and chromosomal origin?
 - D. What kinds of primary prevention efforts are appropriate for SLPs?
 - E. What is the role of the SLP in secondary prevention of communicative disorders?

Functional Communication Measures for Child Language

Spoken Language Production

Level 1: Child attempts to communicate, but attempts are not meaningful to familiar or unfamiliar individuals at any time.

Level 2: Child attempts to communicate, but even with consistent maximal cueing, child rarely produces meaningful communication with familiar people in routine situations.

Level 3: With moderate cueing the child usually produces meaningful communication in routine events of daily living with persons familiar to the child. This communication is much simpler than expected for chronological age.

Level 4: With minimal cues, child can communicate in routine events of daily living. When moderate cues are given, child occasionally communicates in familiar and novel settings, using simpler sentences than are appropriate for his chronological age.

Level 5: With minimal cues, child usually communicates in familiar and novel settings, using simple sentences than are appropriate for his chronological age. With maximal cueing, child occasionally uses age-appropriate sentences in familiar settings.

Level 6: Child usually communicates using age-appropriate sentences in most adult-child, peer, and directed group activities but some limitations are still apparent. Minimal cueing is occasionally required from the communication partner.

Level 7: Child ability to participate in adult-child, peer, and directed group activities is not limited by language production. Cueing is rarely required.

Spoken Language Comprehension

Level 1: Child understands a limited number of common object and action labels and simple directions only in highly structured, repetitive daily routines, with consistent maximal cueing.

Level 2: Child understands a limited number of common objects and action labels and simple directions only in highly structured repetitive daily routines.

Level 3: Child understands a limited number of common objects and action labels and simple directions in novel situations.

Level 4: Child understands simple word combinations/sentences. Child usually requires rephrasing and repetition to ensure understanding of brief conversations.

Level 5: Child understands brief conversations. Child usually requires rephrasing and repetition to ensure understanding of the type and length of sentence typically understood by chronological age-matched peers.

Level 6: Child understands communication of the type and length typically understood by chronologically age-matched peers but occasionally requires rephrasing and repetition. Child's ability to participate in adult-child, peer, and group activities is sometimes limited by language comprehension.

Level 7: Child's ability to participate in adult-child, peer, and group activities is not limited by language comprehension. Repetition and rephrasing are rarely required.

Special Consideration for Special Populations

CHAPTER OBJECTIVES

Readers of this chapter will be able to:

1. Describe the similarities and differences between the speech, language, and communication profiles of children with disorders of known genetic origin and more primary developmental language disorders.
2. Discuss language disorders and differences associated with sensory impairments.
3. Describe the ways in which acquired language disorders in children differ from congenital developmental language disorders.
4. Highlight the language and communication impairments associated with psychiatric disorders of complex genetic origin.
5. Explain the role of extreme environmental disadvantage in language and communication impairment.
6. Evaluate the overlap between developmental language disorders and literacy disorders.
7. Consider the particular challenges that arise when assessing language and communication in the non-verbal child.
8. Discuss the relationship between social, cognitive, and emotional factors in language development and disorder.

Our perspective in this book is that it is more important in clinical practice to describe the nature of a child's language disorder than to get to the root cause of the problem. We discussed earlier how the diagnostic category in which a child is placed may not always either explain or predict language and communication behavior. We know there is considerable variability within a single diagnostic category; sometimes the differences between children with the same "diagnosis" are as striking as the similarities. We've also talked about the fact that many children don't fit very neatly into one diagnostic classification. The causal model we outlined in Chapter 1 (see Figure 1-1) gives us a clue as to why this is so: several genetic, environmental, and cognitive risk factors are common across disorders, increasing the chances that children may have symptoms of different disorders at the same time. For example, many children with intellectual disability (ID) have characteristics of autism spectrum disorder (ASD) and many children with ASD have additional intellectual disabilities. Finally, we've said that knowing a child's diagnostic label often doesn't precisely indicate a specific child's assessment or intervention needs. Knowing that a nonverbal child has ASD, for example, does not automatically prescribe the program. Should he or she be given intervention in the speech modality, or should an alternative modality such as

sign language be introduced? This decision is not very different from the decision that must be made in the case of a non-speaking child who has a hearing impairment or a severe motor speech disorder.

Is there any reason then, to use diagnostic labels in clinical practice? Although diagnostic category may not be the primary determiner of clinical decisions in developmental language disorders (DLD), knowledge of different diagnostic groups can be useful in a number of ways. First, a diagnostic label may be necessary to secure access to SLP services and educational support. The SLP alone will not usually be responsible for the diagnosis, but is likely to contribute to multidisciplinary team assessments that gather evidence of a child's speech, language, communication, and literacy needs. In the case of a child with ASD, for example, the SLP may be required to document the social communication difficulties the child displays, which are part of the core symptoms of this condition. To fulfill this role, it is important to know the standard definitions of each disorder. That's one reason we discuss diagnostic criteria in this chapter.

Second, although the etiological classification associated with DLD does not dictate the assessment and intervention strategies appropriate for each child, knowing the classification often provides hints about what areas to look at in the assessment or what areas might receive priority in intervention. For example, if we know that a child has ASD, we can make an informed guess that pragmatic aspects of language will be impaired, among other things. This could suggest that we include a detailed pragmatic evaluation in our assessment plan. In addition to the key aspects of language likely to be compromised in a given disorder, many disorders have associated cognitive or perceptual impairments that will influence the course of language development. Knowing what these are and how they impact children's language can help us devise interventions, or modify the child's environment in a way that minimizes the negative effects of associated deficits. Remember however, that, although characteristics may be typical of a particular diagnostic group, they are by no means inevitable or universal. Not all children with ASD echo language, for example, although echolalia is a typical symptom of this disorder. Diagnostic categories provide signposts for assessment and intervention; these must be followed through with a detailed description of the individual's actual needs and abilities.

Third, the clinical reports and medical histories of clients often contain information about the diagnostic categories. To read these documents intelligently, we need to understand what the labels mean. In this chapter, we will look at some of the major developmental disorders that are often associated with language impairment. We will outline standard definitions of each of these conditions, then talk about the typical cognitive, linguistic, and literacy characteristics of each disorder, and the implications of these learning challenges for clinical practice in speech-language pathology.

Language disorders can be associated with a variety of congenital conditions.

INTELLECTUAL DISABILITY

Meredith had been a placid baby. She sat up late, not until 9 months of age. She didn't walk until she was 25 months old, and hardly talked at all before her third birthday. Her parents expressed some concern to their family doctor, who referred Meredith for an evaluation when she was 3½. Meredith's cognitive skills were found to be even more delayed. Her parents were interviewed about her self-help skills, and they reported that she did not have independent feeding and wasn't yet toilet trained. Her parents said Meredith acted more "like a 2-year-old" than a preschooler. After some observations of Meredith's play and further discussion with her family, Meredith's parents were told that she had global developmental delays and recommended that she be enrolled in a preschool program for children with special educational needs. Her parents were distressed to learn that her problems were serious, but relieved that their concerns were justified and that help was available.

Meredith is just one example of the kind of child who can receive the diagnosis of developmental or intellectual disability and has just one of the several possible types of communicative disorders associated with her diagnosis. In Meredith's case, as in a significant proportion of cases with ID, the cause of disorder is unknown. Diagnosis of ID in these cases is based on behavioral rather than medical characteristics, and the cause of disorder is not necessary for diagnosis or intervention decisions. Let's look first at the standard definition of ID and caveats associated with that diagnosis. We'll then consider some of the typical (but, of course, by no means universal) relationships between language and communication skills and level of nonverbal cognitive ability. Finally, we'll consider developmental language disorders that accompany ID in the context of known genetic etiology. The most important thing to remember is that, even if we know a child's IQ score and the genes that play a causal role in ID, we cannot accurately predict what the

child's language profile will be or how it will change over time. Careful assessment of form, content, use, and literacy development is therefore needed.

Definition and Classification

The American Association on Intellectual and Developmental Disabilities (AAIDD, www.aaidd.org) provides the following definition of intellectual disability (Schalock et al., 2010):

"Intellectual disability is a disability characterized by significant limitations both in intellectual functioning and in adaptive behavior, which covers many everyday social and practical skills. This disability originates before the age of 18."

In addition, the AAIDD (2010) diagnosis requires that:

1. Limitations in present functioning must be considered within the context of community environments typical of the individual's age, peer group, and culture.
2. Valid assessments consider linguistic and cultural differences in the way people communicate, move, and behave.
3. Within an individual, limitations often coexist with strengths.
4. The major purpose of describing limitations is to develop a profile of needed supports.

These conditions help to ensure that, if appropriate, individualized supports are provided over a sustained period, which will improve the person's level of life functioning.

The AAIDD provide definitions of intellectual and adaptive function. Intellectual functioning, or intelligence, refers to general mental capacity, such as learning, reasoning, and problem solving. This may be operationalized on the basis of IQ test scores; generally, an IQ test score of around 70 to 75 indicates a limitation in intellectual functioning. This range of scores translates to a criterion of at least 2 standard deviations below the mean (a standard score of 100). You'll remember from Chapter 2 that fewer than 3% of a normally distributed population will score farther from the mean than -2 SD (see Figure 2-11). You'll note that this is not an absolute score; the inclusion of adaptive skills in the definition leaves open the option of diagnosing an intellectual disability in an individual who has borderline IQ scores and significant limitations in adaptive behavior.

According to the AAIDD, adaptive behavior comprises three skill types: *conceptual skills*—language and literacy; money, time, and number concepts; and self-direction; *social skills*—interpersonal skills, social responsibility, self-esteem, gullibility, naïveté, social problem solving, and the ability to follow rules/obey laws and to avoid being victimized; and *practical skills*—activities of daily living (personal care), occupational skills, healthcare, travel/transportation, schedules/routines, safety, use of money, and use of the telephone. Note that deficits in adaptive behavior must be *relative to the individual's cultural group*. This criterion is necessary because people from diverse cultural backgrounds may have different expectations of individuals at different ages. In mainstream American culture, we expect children to be able to separate from their mothers easily at age 5 for example; other cultures expect much longer-term dependency on mothers. In the past, too many children were classified as having an intellectual disability because their experiences were different from those of middle-class children, which resulted in their scoring low on IQ tests that contained culturally biased items. As we have already discussed, it is also critically important to rule out language differences as a source of "failure to adapt."

Although adaptive behavior is often evaluated subjectively, standardized measures exist for various aspects of adaptive performance. Some examples include: the *Adaptive Behavior Assessment System—2nd edition* (ABAS-2; Harrison & Oakland, 2003), the *Scales of Independent Behavior-Revised* (SIB-R; Bruininks, Woodcock, Weatherman & Hill, 1997), the *Adaptive Behavior Scales-School—2nd edition* (ABS-S-2; Lambert, Nihira & Leland, 1993), and the *Vineland Adaptive Behavior Scales—II* (Sparrow, Cichetti, & Balla, 2005). Ecological inventories and environmental assessments (see Chapter 8) also can be used to assess various aspects of adaptive performance.

The definition of ID also includes the requirement that onset occur before 18 years of age, or during the developmental period. This criterion is used to differentiate ID, which is considered a developmental disorder, from forms of dementia that result in intellectual impairment and deterioration during adulthood. Of course, there can be cases that are difficult to judge. For example, suppose a typically developing child has a serious accident at age 10 that results in brain damage and subsequent IQ scores of more than 2 SD below the normative mean. By the AAIDD definition, this child would be considered to have an intellectual disability (assuming his or her adaptive skills were also compromised) even though the origins of impairment are traumatic rather than developmental. Nevertheless, this child would likely benefit from the types of interventions or supports that other children with ID require. This is an important reminder that clinicians need to determine the child's individual needs rather than focusing too much on diagnostic labels.

For many children, ID occurs in the context of a recognized disorder of known or unknown (complex) genetic origin. However, it is important to remember that this is not always the case. A population study of school-aged children in an urban area of England revealed that 5% to 10% scored below 70 on the WISC, but only 15% of those low scorers were receiving special educational support (Simonoff et al., 2006). Provision of special educational services was more likely to occur if children had overt emotional or behavioral problems in addition to low IQ. Nevertheless, children with low IQ may be struggling academically and it is worthwhile considering the cognitive, linguistic, and literacy abilities of any child not meeting age expectations at school.

Cognitive Characteristics

Early reports of the cognitive profile of individuals with nonspecific ID reported a similar pattern of cognitive development to typically developing children, but a slower developmental trajectory (Owens, 2009). Other researchers have reported a more uneven profile of cognitive development with more pronounced deficits in executive functioning (EF; Willner et al., 2010) and working memory (Henry & Winfield, 2010; Caretti, Belachi, & Cornoldi, 2010) than would be expected given overall level of intellectual ability. Willner et al. noted that, in a cohort of individuals with ID attending day center services, EF skills were not strongly correlated with IQ scores, but that impairments in EF may be more closely associated with impairments in adaptive behavior. Henry and Winfield (2010) considered the relationship between different components of working memory and scholastic attainment in 11- to 12-year-old children with ID. They found that measures of phonological working memory (word and digit repetition) accounted for a large degree of variance in literacy skill, whereas measures of the "central executive" (a listening span task, in which children make true/false judgements about statements while simultaneously remembering the final word of each

statement) were more predictive of numeracy skill. Caretti et al. (2010) indicated that working memory performance in ID was particularly influenced in attentional control and in "updating" information held in temporary store. Cognitive abilities do generally improve throughout childhood and into adulthood, though IQ scores (which take age into account) remain stable throughout development for many individuals (Yang et al., 2010).

Language Characteristics

Delayed language acquisition is often one of the first signs of ID. One question that the clinician is likely to face is whether language skills are in line with nonverbal mental age expectations, or whether language is impaired relative to other cognitive achievements. Both patterns of language acquisition have been observed; Miller and Chapman (1984) estimated that approximately 50% of children with nonspecific ID had language skills commensurate with nonverbal abilities. The remainder have more uneven profiles; 25% had expressive language deficits relative to comprehension skill (which was on par with nonverbal mental age) while the remainder had deficits in both comprehension and expression. This variation may be related to differences in cognitive abilities, for instance the differences in working memory and attention control we discussed earlier (Abbeduto & Boudreau, 2004).

Form

In general, the acquisition of specific grammatical devices follows a typical developmental sequence, albeit at a slower developmental pace. However, once the mean length of utterance (MLU) is above 3, children with ID tend to use shorter, less complex sentences with fewer elaborations and relative clauses than do typical peers at the same MLU level (Abbeduto & Boudreau, 2004).

Content

It has generally been thought that vocabulary is easier for children to learn than syntax; however, recent research suggests this may be artifact of test selection (Chapman, 2006). Specifically, the *Peabody Picture Vocabulary Test (PPVT IV)* (Dunn & Dunn, 2007) exaggerated differences between IV vocabulary and syntax in adolescents with nonspecific ID relative to the vocabulary subtest of the *Test of Auditory Comprehension of Language—3* (Carrow-Woolfolk, 1999). On this measure, age-equivalent scores did not differ significantly from syntactic measures. Chapman (2006) concluded that, while vocabulary size may be an advantage in ID, conceptual knowledge is more in keeping with developmental expectations (see also Norbury, Griffiths, & Nation, 2010, for a similar pattern of results in autism spectrum disorder).

Use

The ability to use language meaningfully in social contexts is an important component of adaptive behavior, yet the pragmatic skills of children with nonspecific ID have attracted relatively little research attention. Pragmatic competence in everyday situations requires the integration of cognitive, linguistic, and social-emotional cues, making it particularly vulnerable in ID. Not surprisingly then, the evidence that exists suggests that pragmatic development often lags behind cognitive development, though it may not be qualitatively different (Abbeduto & Boudreau, 2004; Abbeduto & Hesketh, 1997). Specifically, individuals with ID may be slow to develop intentional communication in the pre-verbal stages of development. Once some language is acquired, children with ID are able to engage in socially meaningful conversations, with adequate turn-taking and topic maintenance skills. However, they may be less able to clarify meaning and request clarification when they

have not understood utterances. In addition, using language forms for different social purposes may also be challenging. Recent research suggests that individuals with ID have considerable difficulties constructing coherent narratives (Murfett, Powell, & Snow, 2008), but are able to make use of gestural supports to enhance understanding, particularly in the context of understanding verbal humour (Degabriele & Walsh, 2010).

Literacy

Like other aspects of language development, literacy is slower to progress for children with ID. However, just as we see in typical development, phonological processing skills predict word and non-word reading in this population (Wise et al., 2010), while word reading and oral language skills predict reading comprehension abilities (Verhoeven & Vermeer, 2006). Differences in literacy achievement are not caused by lack of reading opportunity in the home literacy environment; van der Schuit et al. (2009) demonstrated that parents of children with ID provided similar literacy opportunities as other families, although the children with ID initiated these activities less often. Home literacy experiences were associated with the child's verbal and nonverbal abilities, indicating that parents adapt their level of engagement to the child's linguistic abilities.

Summary

Nonspecific ID is relatively common, with a prevalence of approximately 1%, and can have profound implications for language development and academic success. In general, children with nonspecific ID follow a typical trajectory at a much slower developmental pace. However, at times language and communication skills may be out of step with nonverbal abilities. The acquisition of particular language forms does not guarantee that children will automatically use these forms in socially appropriate ways, which may further interfere with the development of adaptive behaviors. These are key aspects of development to consider, and each individual will require a thorough assessment of language abilities in different environmental contexts, supplemented by detailed discussion with families about successes and challenges in daily communication.

DLD ASSOCIATED WITH DISORDERS OF KNOWN GENETIC ORIGIN

Down Syndrome

Down syndrome (DS) is the most common genetic cause of intellectual disability, occurring in approximately 1 in 700 live births (Canfield et al., 2006). DS is named for John Langdon Down, the nineteenth-century English physician who first published a description of a group of clients with the syndrome. In the majority of cases, DS results from an extra (third) copy of chromosome 21 (which is why it is sometimes referred to as trisomy 21); increasing maternal age significantly increases risk of Down syndrome (see Fidler & Daunhauer, 2011 for a comprehensive review of etiological factors). Down syndrome is characterised by mild to moderate ID, hypotonia (low muscle tone), distinctive facial features such as microgenia (an abnormally small chin), round face, macroglossia (protruding or oversized tongue), epicanthal fold (fold of skin on the eyelid), short stature and shorter limbs, and hyperflexibility of joints (Figure 4-1). DS is also associated with a number of health concerns including a higher risk for congenital heart defects, gastroesophageal reflux disease, recurrent ear infections, obstructive

FIGURE 4-1 Children with Down syndrome have characteristic features. (Reprinted with permission from Zitelli, B.J., and Davis, H.W. [2002]. *Atlas of pediatric physical diagnosis* [ed 4]. St. Louis, MO: Mosby.)

sleep apnea, and thyroid dysfunction. Co-morbid autism is diagnosed in 10% of children with DS, though there is debate concerning the degree to which severe cognitive impairments increase the likelihood of a dual diagnosis. As individuals with DS are now living longer, it has become apparent that adults with DS are at greatly increased risk of experiencing early onset Alzheimer's disease. In DS, the earliest symptoms of Alzheimer's disease are marked changes in behavior, rather than cognitive decline (Nelson et al., 2001).

Cognitive Characteristics

Children with DS experience global developmental delays in fine and gross motor skills. These motor delays are accompanied by mild to moderate intellectual disability, with the majority of IQ scores between 40 and 70 (Hodapp, Evans, & Gray, 1999). Individuals with DS generally have an uneven profile of cognitive development that may impact on language development and language processing. For instance, they have marked deficits on measures of working memory, but these are more pronounced with verbal material relative to visuospatial working memory (Lanfranchi, Jerman, & Vianello, 2010), a pattern that appears to be unique to DS and not other syndromes of ID (Edgin, Pennington, & Mervis, 2010). Executive functions, the cognitive processes integral to adaptive, goal-directed actions, are vulnerable in DS (Kittler, Krinsky-McHale, & Devenny, 2008). These include problems with response inhibition (impulse control), cognitive flexibility, and planning. Limitations in response inhibition have been linked to reduced generation of strategies for delaying gratification, difficulties persisting with learning tasks, and engaging in more off-task behavior (Kopp et al., 1983, Vlachou & Ferrell, 2000). Individuals with DS have greater difficulty than mental-age-matched comparison groups learning new rules and applying them (Lanfranchi et al., 2010). They also take

longer to solve problems and are more likely to abandon efforts at problem solving, reflecting difficulties with planning and persistence (Fidler et al., 2005; Lanfranchi et al., 2010). Clearly, deficits in executive skills can impact academic performance as children with DS struggle to stay on task and monitor and adapt their own behavior to achieve learning goals.

Language Characteristics

The most consistently reported language profile in DS is one in which expressive language is more severely impaired than receptive language abilities (Laws & Bishop, 2003). Here we consider language development and disorder in DS in relation to form, content, use, and literacy.

Form

Speech intelligibility in DS is poor relative to cognitive ability and is particularly pronounced in connected speech (Barnes et al., 2009). Most speech sound errors are developmental in nature (e.g., cluster reduction and final consonant deletion) though some atypical errors are also evident, such as vowel distortions and inconsistent pronunciations (Cleland et al., 2010). Reduced intelligibility may be attributed in part to anomalies of the articulatory structures or complications arising from frequent bouts of middle ear infection (Martin et al., 2009). Apraxia of speech has also been reported in DS (Rupela & Manjula, 2007), suggesting assessment of oral-motor structure and function is warranted.

Like children with primary DLD, children with DS appear to have disproportionate difficulties acquiring and using syntax (Chapman, 2006; Laws & Bishop, 2003). Syntactic comprehension is characterised by slowed growth and even decline in late adolescence (Laws & Gunn, 2004) and is more impaired than overall cognitive ability and vocabulary size (Caselli et al., 2008; Price, Roberts, Vandergrift, & Martin, 2007). Expressive syntax presents even greater challenges and can be an earlier indicator of language difficulties. Children with DS produce shorter and less complex sentences and fewer question/negation forms than typically developing peers matched for nonverbal mental age (Caselli et al., 2008; Price et al., 2008). Similarities and differences have also been noted between the grammatical profiles of individuals with DS and individuals with other DLDs (Ypsilanti & Grouios, 2008). For instance, numerous similarities between DS and more specific language impairments have been noted (Laws & Bishop, 2004) with particular limitations in tense marking (past tense –ed; third person singular –s) (Caselli et al., 2008; Laws & Bishop, 2003). On the other hand, individuals with DS appear to have more pronounced grammatical deficits relative to other groups with ID of known genetic origin. For instance, Price et al. (2008) reported that grammar was more severely impaired in DS than in Fragile X syndrome and that differences persist into adolescence and early adulthood (Finestack & Abbeduto, 2010).

Content

Acquisition of first words in DS is significantly delayed and subsequent growth of expressive vocabulary is slower than expected (Berglund, Eriksson, & Johansson, 2001). Once words are acquired, there is some debate as to whether vocabulary keeps pace with nonverbal cognitive abilities, and whether there are asymmetries in receptive/expressive vocabulary as there are in grammatical development. Some investigators have reported receptive vocabulary scores in line with cognitive expectations (Laws & Bishop, 2003), whereas others have reported that expressive vocabulary is impaired relative to peers matched on nonverbal IQ (Caselli et al., 2008; Price et al., 2007). Differences between studies may be due, in part, to differences in the vocabulary measures used (cf. Chapman,

2006), though differences in participants (hearing status or parental education levels) cannot be ruled out.

There is some evidence that gesture is preferentially used by young children with DS and supports vocabulary comprehension, and may be predictive of later vocabulary development (Zampini & D'Odorico, 2009). Individuals with DS are proficient in using referential cues to learn new words (McDuffie, Sindberg, Hesketh, & Chapman, 2007) but word learning and vocabulary growth may be hampered by limitations in phonological short-term memory (Jarrold, Thorn, & Stephens, 2009).

Use

Pragmatics is generally considered to be an area of strength for individuals with DS, although early joint communicative behaviors such as mutual eye contact, vocalizations, and dyadic interactions with caregivers may be delayed or less coordinated than those observed in typically developing (TD) infants (Berger & Cunningham, 1983; Jasnow et al., 1988). By the age of two, infants with DS catch up, with many children with DS showing more social-interactive behaviors than TD peers (Mundy et al., 1988). Children with DS use the same variety of communicative functions (comment, answer, protest) as language- or nonverbal ability-matched younger children, though they demonstrate fewer requesting behaviors (Beeghly et al., 1990).

Conversational development is also an area of strength, as children with DS demonstrate high levels of contingent responding and topic maintenance (Beeghly et al., 1991; Tager-Flusberg & Andersen, 1991). Narrative skills of children with DS also reflect a good conceptual understanding of the story. When narrating a wordless picture book, children with DS produce more plot lines and thematic elements relative to MLU-matched peers (Miles & Chapman, 2002). This narrative strength may depend in part on the level of support provided. For instance, when asked to narrate stories without picture support, individuals with DS may recall fewer important story elements (Kay-Raining Bird, Chapman, & Schwartz, 2004; Murfett, Powell, & Snow, 2008).

Other aspects of language use may be vulnerable. Roberts et al. (2007) reported that children with DS provided fewer elaborative utterances in conversational turns relative to peers matched for nonverbal ability, instead providing minimally adequate replies. In addition, individuals with DS are less likely to signal non-comprehension of language or request clarifications in referential communication tasks (Abbeduto et al., 2008). Abbeduto et al. reported that the ability to request clarification was associated with vocabulary and syntactic skills, highlighting the strong links between core language skills and use of those skills in social contexts. These pragmatic behaviors may also be associated with executive skill, and particularly the ability to monitor comprehension, though further research is needed in this area.

Literacy

Reading skills of children with DS are extremely variable and little is known about the proportion of children with DS who achieve reading proficiency (Martin et al., 2009). It is clear that, like other aspects of language development, literacy development in DS follows a protracted, though qualitatively similar, developmental course (Cardoso-Martin, Peterson, Olson, & Pennington, 2009). For example, as in the case of typical development, word and non-word reading in DS is intimately related to phonological processing skills (Lemons & Fuchs, 2010; Roch & Jarrold, 2008). Comparison of word reading and comprehension skills suggests that individuals with DS are more likely to have a profile similar to that of “poor comprehenders” in which word reading abilities

outstrip reading comprehension skills (Roch & Levorato, 2009). Poor reading comprehension was associated with levels of oral language comprehension, suggesting that oral language comprehension should form the foundations of educational interventions aimed at improving literacy skill for this population (cf. Clarke et al., 2010).

Implications for Clinical Practice

In summary, children with DS have a protracted rate of language and literacy development. Striking similarities between DS and more specific DLDs have been noted: relative strengths in vocabulary and pragmatic skill in the context of pronounced difficulties in syntax, morphosyntax, and phonological/verbal memory. Literacy is also particularly vulnerable, with increased risk of poor reading comprehension. Special considerations for this population include the need to monitor hearing, because of recurrent ear infections, and the need to give detailed consideration to oral-motor structure and function, and how anomalies in oral-motor development may affect speech production and intelligibility.

Detailed assessment of language attainments is necessary and we cannot assume that level of nonverbal ability will be predictive of language skill. We should also be cautious in assuming that acquisition of a particular skill results in appropriate use of that skill for learning or social exchanges. Observation and analysis of language in less structured contexts is warranted. Finally, children with DS demonstrate strengths in visual-spatial memory, and using gesture and other social cues may support comprehension and learning of new information. Any assessment profile should therefore detail the child's communication strengths as well as his or her needs, as these strengths may be usefully exploited in intervention contexts.

With regard to intervention, the ultimate goal should be to improve functioning in communication, academic, social, and vocational areas (American Speech-Language and Hearing Association [ASHA], 2005a). Decisions about what to prioritize in invention should be made in collaboration with families and clients themselves, and should focus not just on developing skills, but on the functional use of those skills in academic, vocational, and social contexts. With this in mind, Martin et al. (2009) suggest that general priorities for working with DS populations will be to target early communication using milieu communication techniques (see Chapter 3) with families to support development of early vocalizations, gesture, and eye gaze to initiate and respond to "conversational" exchanges (cf. Fey et al., 2006). Martin et al. also advocate targeting speech skills, complex language structures, and early literacy skills. While reading development may be seen as an outcome of early intervention strategies, there is also evidence that using written language in intervention programs may, because of its visual modality, support oral language, speech, and memory development in DS (Roberts et al., 2008; Laws, 2010).

In addition to improving language skills, it is worth remembering that children with DS may need support in attending to relevant information, staying on task, and recognising/signalling when they have not understood something. Providing strategies for these behaviors is critical to academic achievement. Finally, it may be prudent to consider using augmentative or alternative communication to improve the communicative competence of children with DS. Many children with DS use sign language and there is general agreement that the use of sign may support their language acquisition (see Brady, 2008).

Williams Syndrome

Definition and Classification

Williams syndrome (WS) is a complex neurodevelopmental disorder that results from the deletion of approximately 25 genes on one copy of chromosome 7q11.23 (Osborne, 2006). It is a relatively rare disorder with a prevalence rate of 1 in 7,500 live births (Stromme et al., 2002). WS is associated with multiple physical, cognitive, and behavioral features. Physical features include characteristic facial dysmorphology (Figure 4-2), cardiovascular heart disease, growth deficiency, and connective tissue abnormalities. The striking behavioral phenotype is one of overfriendliness, social gregariousness, and marked anxiety (see Mervis & John, 2010, for review).

Cognitive Characteristics

Infants and toddlers with WS experience global developmental delays, and older children and adults with WS generally have mild to moderate ID. Some individuals will have IQs within the low average range, while others will experience more severe impairment (Mervis & John, 2010). Apart from general ID, WS is associated with a unique profile of cognitive strengths and weaknesses. Most notably, children with WS have profound difficulties with visual-spatial construction, with scores on the Spatial Cluster of the *Differential Ability Scales* (Elliot, 2007) some 20 points lower than scores on other intelligence scales (Mervis & John, 2010). These cognitive deficits occur in the context of difficulties with adaptive behavior, particularly in the areas of motor development and independent living (Mervis & Morris, 2007).

Language Characteristics

Traditionally, WS has been put forward as the archetypal evidence for dissociations between cognitive and linguistic skill, with some suggesting "exquisite mastery" of syntax and vocabulary in the context of pronounced nonverbal cognitive deficits (cf. Piatelli-Palmarini, 2001). Recent investigations provide a more nuanced view of the relationship between language and cognition. For a

FIGURE 4-2 Children with Williams syndrome have an upturned nose and small chin. (Reprinted with permission from Zitelli, B.J., and Davis, H.W. [2002]. *Atlas of pediatric physical diagnosis* [ed 4]. St. Louis, MO: Mosby; courtesy R.A. Mathews, MD, Philadelphia.)

start, the onset of first words and phrases is almost always delayed in WS. Once words have appeared, the pattern of linguistic strengths and weaknesses closely mimics those observed in non-verbal cognition. Let's look at this in a little more detail.

Form

Canonical babbling is significantly delayed in infants with WS relative to age-matched infants (Mervis & Becerra, 2007). Onset of babbling is predictive of onset of word production. There are no reports of significant speech sound disorders or reduced intelligibility in older, verbal children with WS.

Initial reports of grammatical development suggested that grammar was "intact" and much better than expected for overall level of nonverbal cognitive ability. Indeed, when compared with ability-matched peers with Down syndrome, the grammatical skills of children with WS are superior (Joffe & Varlokosta, 2007). However, Mervis and John (2010) point out that these findings may reflect the more pronounced grammatical limitations that characterize children with DS rather than demonstrating superior grammatical skills in WS. When compared to younger typically developing children with equivalent cognitive levels or to other participants with ID, grammatical skills are more in line with, or sometimes below, developmental expectations (Mervis & Becerra, 2007). Deficits in grammatical understanding are evident, but these are strongly related to verbal working memory abilities and general levels of cognitive ability (Mervis & John, 2010).

Content

Understanding and production of concrete vocabulary are relative strengths for individuals with WS, resulting in consistently higher scores on measures of vocabulary such as the *PPVT* (Dunn & Dunn, 2007) and the *Expressive Vocabulary Test* (Williams, 2006), relative to other language measures (cf. Brock, 2007). However, as we've seen in our earlier discussions, this profile is not unique to WS and characterizes many DLDs. What is less common across disorders is the profound difficulty with relational or conceptual vocabulary experienced by individuals with WS. This vocabulary is important for marking spatial, temporal, and dimensional concepts as well as for devices such as conjunction and disjunction. Deficits with these terms mimic deficits in spatial abilities (Mervis & John, 2008).

Use

In contrast to children with DS, children with WS have pronounced pragmatic difficulties, despite the superficial air of social skill. The emergence of joint attention is delayed and there is an atypical temporal relationship between gesture and word production. In typical development (as well as in DS), referential gestures such as pointing precede referential word production (Mervis & Becerra, 2007).

Although WS is often conceptualized as the "opposite" of ASD because of the increased interest in social interaction in WS, systematic investigation has highlighted overlaps between the two disorders. For example, although children with WS are more likely to look at faces than children with ASD, their ability to integrate gaze cues for communication purposes is impaired (Lincoln et al., 2007). Even when children do meet criteria for ASD, a significant proportion of children with WS have marked pragmatic difficulties on parent-report measures such as the *Children's Communication Checklist* (Bishop, 2003). Laws & Bishop (2004) reported that 79% of children with WS studied were rated as having pragmatic difficulties. These pragmatic difficulties are evident in conversational behavior, in which individuals with WS are less likely to provide contingent and informative responses than peers with more

specific DLDs (Stojanovik, 2006). In addition, qualitative differences in narrative skill have been reported; relative to other populations with ID, children with WS made considerably more social evaluative statements and fewer cognitive inferences (Reilly et al., 2004). Like other children with ID, children with WS have more difficulty monitoring their own comprehension and signalling when their conversational partners provide ambiguous or inadequate messages (John et al., 2009).

Literacy

The reading skills of children with WS are variable, with some achieving word recognition and non-word reading skills that are broadly in line with their nonverbal abilities whereas other are unable to read at all (see Mervis, 2009, for review). Consistent with reading profiles seen in other populations with ID, reading comprehension scores are generally significantly lower than word reading abilities (Laing et al., 2001).

Implications for Clinical Practice

Mervis and John (2010) suggest that intervention approaches developed for other populations with ID and social impairments can also be used for children with WS. In particular, working with families to develop language and communication is a priority for young children with WS. Language intervention is likely to be necessary throughout the school years; the focus of intervention may change and should emphasize use of language targets in academic and socially meaningful contexts. Social skills training for older children is also advocated; these not only aim to promote socially appropriate communication behaviors, but could help children with WS to be more discerning in approaching others and in reading more subtle social-communication cues. To date, only one study has explored literacy intervention in this population. Mervis (2009) suggests that a systematic phonics based approach in the context of direct reading instruction is preferable to a whole word approach for these children. Oral language instruction aimed at improving reading comprehension is also likely to be important (cf. Clarke et al., 2010) and will need to be complemented by explicit strategies for comprehension monitoring and linking text information to general knowledge.

Fragile X Syndrome

Definition and Classification

Fragile X syndrome (FXS) is a single gene disorder, caused by an expansion of the trinucleotide (CGG), which repeats too often on the fragile X mental retardation gene (FMR1), which is located on the bottom end of the X chromosome (see Hagerman, 2008 for extensive review). Typical individuals have 5 to 44 repetitions on FMR1; premutation carriers of FXS have 55 to 200 repeats, while individuals with the full mutation have in excess of 200 CGG repeats (Schneider, Hagerman, & Hessel, 2009). This expansion leads to eventual silencing of the FMR1 gene, reducing or completely eliminating production of its associated gene protein, FMRP (Oostra & Willemsen, 2003). FMRP is critically important for experience-dependent neural development, particularly for the maturation of synapses and synaptic pruning in the developing brain; as such, there is a direct positive correlation between the amount of FMRP expressed and level of cognitive functioning (Schneider, Hagerman, & Hessel, 2009).

Unlike Down syndrome, which is not passed down from one generation to another, FXS is an inherited disorder, and is the most common inherited form of ID. FXS occurs in approximately 1 in

4000 males and 1 in 8000 females; it is more common in males because males have only one X chromosome. The prevalence of the premutation is much more common, with approximately 1 in 250 females and 1 in 600 to 800 males having the premutation (Beckett, Yu, & Long, 2005). The full mutation is associated with a characteristic, though variable, physical and behavioral phenotype. Boys with FXS do not have clearly dysmorphic features and are often difficult to identify before the age of 3, unlike children with DS, whose physical features are noticeable from birth. With increasing age, however, characteristic physical features emerge (Figure 4-3). These include elongated face, long and prominent ears, highly arched palate, enlarged head, hypotonia, flat feet, hyperextensible finger joints, and large testicles (macroorchidism). FMRP is also associated with the formation of connective tissue; medical difficulties associated with FXS therefore include occasional joint dislocations, recurrent otitis media, strabismus, mitral valve prolapse, and/or dilation at the base of the aorta and gastrointestinal reflux, which is seen in the majority of male infants with FXS (Hagerman & Hagerman, 2002).

Co-morbid conditions are extremely common in FXS and affect language development and disorder. Most striking are the high rates of autism spectrum disorder identified in males with the full FXS mutation; approximately 30% to 50% of boys with FXS meet criteria for a diagnosis of autism spectrum disorder (Harris, 2008). This makes FXS the single largest known genetic cause of ASD, though only 2% to 6% of ASD cases can be attributed to FXS (Reddy, 2005). Although we've mentioned that level of FMRP expression is predictive of cognitive ability, it does not appear to be associated with severity of ASD symptoms (Loesch et al., 2007). It is clearly important to distinguish the cognitive and language characteristics of individuals with FXS who also have ASD

from those who do not. Other co-morbidities include attention-deficit hyperactivity disorder (ADHD), which is reported to affect 44% to 93% of children with FXS meeting diagnostic criteria for ADHD (Sullivan et al., 2006); seizures, which affect approximately 20% of males; and high rates of anxiety, reported in a national parent survey to affect approximately 70% of males and 56% of females (Bailey et al., 2008).

Cognitive Characteristics

ID is the predominant cognitive characteristic; nearly all males have a degree of ID that is similar to that seen in DS. Females tend to have less severe ID; approximately 25% have IQ scores less than 70, though about half have borderline IQ scores (Cornish, 2008). The rate of intellectual growth is reported to be about half that of typically developing children, the gap between individuals with FXS and their peer group increases with time, causing an age-dependent gradual decline in IQ (Hall et al., 2008). In addition to cognitive impairment, a core deficit in executive function has also been proposed, with significant deficits in sequential processing, working memory deficits, cognitive flexibility, planning, selective attention, inhibitory control problems, and fine and gross motor delay (Hooper et al., 2008).

Of course, there are pockets of relative cognitive strength, which include simultaneous processing and long-term memory (see Finestack, Richmond, & Abbeduto, 2009, for review). Intriguingly, a longitudinal investigation of academic achievement in FXS found that nonverbal IQ and FMR protein expression were not associated with academic level or rate of change in academic performance; however, autistic behavior and level of maternal education were significantly related to academic achievement scores (Roberts et al., 2005).

Language Characteristics

Gender differences in language attainment are particularly pronounced in FXS, with girls invariably demonstrating higher levels of linguistic competence relative to males with FXS. It will be absolutely essential for the clinician to establish whether co-morbid ASD is present as this will have significant implications for language development and particularly the social use of language. It is also important to realize that the bulk of research in FXS has been directed at understanding the genetic pathways to behavior; as a result very little is known about environmental influences on language development in FXS, or whether modifying the language-learning environment can positively alter developmental trajectories (Finestack et al., 2009).

Form

In general, the speech sound production of boys with FXS is commensurate with nonverbal mental age expectations. Barnes et al. (2008) reported that, regardless of ASD status, boys with FXS did not differ from their younger typically developing peers on phoneme accuracy or the number of developmental phonological processes, though they were less intelligible in connected speech. While speech articulation is a relative strength, phonological processing is less well developed in FXS, with many children scoring below the 10th percentile on measures of phonological awareness (Buckley & Johnson-Glenberg, 2008) and demonstrating significant impairments in phonological short-term memory (Baker et al., 2011).

Compared to younger typically developing children matched for nonverbal ability, boys with FXS are delayed in both their understanding and production of grammar and morphosyntax

FIGURE 4-3 Boys with fragile X syndrome typically have long, narrow faces and large ears. (Reprinted with permission from Simko, A., Hornstein, L., Soukup, S., and Bagamery, N. [1989]. Fragile X syndrome: Recognition in young children. *Pediatrics* 83, 547-552.)

(see Finestack et al., 2009 for review). Impairments are noted on both standardized measures and analyses of more spontaneous language samples. For example, boys with FXS have shorter MLUs relative to matched comparison groups even when nonverbal mental age and level of maternal education has been taken into account (Roberts et al., 2007). In addition, less complex noun and verb phrases are evident in conversational language, though production of questions/negation may be more in line with nonverbal skills. Where direct comparisons have been made, the expressive and receptive grammatical skills of boys with FXS are somewhat better than boys with DS, and are comparable in individuals with and without co-morbid ASD (Price et al., 2007, 2008).

Content

Investigations of receptive vocabulary knowledge in FXS have yielded mixed results, with some investigators reporting weaker vocabulary scores and others suggesting that vocabulary is commensurate with nonverbal mental age expectations (Finestack et al., 2009). A more consistent finding is that expressive vocabulary, as measured by number of different words used in connected discourse, is impaired and rates of vocabulary growth are slower than those seen for younger typically developing children (Roberts et al., 2002). In general, the presence of co-morbid ASD does not result in more severe vocabulary deficit (Kover & Abbeduto, 2010), though the small number of children with co-morbid diagnoses means we should be cautious in assuming this is always the case.

Studies to date have focused on lexical diversity in discourse; there is a dearth of research evidence about what children with FXS understand about the words they use. We also know very little about the integrity of semantic networks in FXS or about how flexibly children with FXS use their semantic knowledge, for example in understanding figurative expressive or verbal humor.

Use

Pragmatic competencies are perhaps most closely aligned with ASD status in boys with FXS. Qualitatively different language characteristics have been reported including increased use of tangential language, perseverative and repetitive speech, delayed echolalia, and use of stereotyped phrases (Cornish et al., 2004). These qualitative differences disrupt conversational exchanges; relative to developmental expectations, boys with FXS have difficulty maintaining coherent, semantically rich conversational exchanges (Roberts, Martin et al., 2007). For example, boys with FXS are more likely to provide conversational turns that are tangential or unrelated, and provide fewer turns in which they add or request new, on-topic information. These anomalies are particularly pronounced in those who also meet criteria for ASD, but are not limited to this subgroup (Roberts, Martin et al., 2007). This raises interesting questions about the source of these conversational errors; in ASD pragmatic errors are largely attributed to deficits in social-cognitive understanding. Children with FXS also show evidence of poor understanding of other people's minds, as indexed by false belief tasks (Grant, Apperly, & Oliver, 2007). However, these deficits appear to be associated with deficits in working memory and executive control (inhibition) rather than social understanding *per se*. This suggests that conversational anomalies may also reflect problems with inhibition and working memory.

Further support for this assertion comes from studies of narrative production; when narratives are elicited in the context of a wordless picture book, no differences have been found between individuals with FXS and ability-matched comparison

groups (Keller-Bell & Abbeduto, 2007). The only exception was in "evaluative" devices, or the extent to which narrators provide socially engaging information about the story such as mental state verbs, character names, character dialogue, and exaggeration. Although children with FXS did not differ from younger, typically developing peers in the use of evaluative devices, they did produce fewer such devices relative to peers with DS, despite providing longer utterances overall (Keller-Bell & Abbeduto, 2007). This study did not differentiate individuals with FXS and co-morbid ASD; such studies are needed to determine the extent to which use of evaluation is linked to more general social interaction behaviors.

Measures of referential communication also reveal pragmatic weaknesses in FXS. For instance, relative to ability-matched peers, boys with FXS are less able to provide consistent, unambiguous language to describe a target shape to listeners (Abbeduto et al., 2006) and are less likely to indicate that the verbal messages of others are inadequate to meet task demands (Abbeduto et al., 2008). In the latter case, signaling noncomprehension was positively correlated with vocabulary and receptive grammar, and associated with gender; girls with FXS were more likely to signal noncomprehension than male counterparts. Again, these findings appear to indicate a reduced appreciation of listener need and/or deficits in executive skill; within-syndrome comparisons of those with/without co-morbid ASD are needed in order to determine how widespread these pragmatic deficits are.

Literacy

Investigations of literacy development in FXS are lacking. Preliminary evidence suggests that children with FXS read words at a level commensurate with nonverbal age expectations but have more significant difficulties reading non-words (Buckley & Johnson-Glenberg, 2008). Finestack et al. (2009) point out that relative strengths in word reading in FXS may be confounded by large age differences between individuals with FXS and their ability-matched typical peers, which affords the FXS group considerably more print exposure than the typically developing children. At present there are no systematic investigations of percentages of children with FXS who develop functional reading. Given oral language weaknesses and pervasive pragmatic difficulties, reading comprehension is likely to present significant challenges to individuals with FXS.

Implications for Clinical Practice

Children with FXS have complex cognitive and behavioral challenges that impact language development and language processing. However, as we've seen with other disorders of known genetic origin, there is a paucity of evidence regarding the best course of clinical action or how therapeutic and educational practices may influence developmental trajectories. Children with FXS are often referred to SLP services when they are very young (Brady et al., 2006); a top priority for the SLP will be to work closely with families and other professionals to ascertain ASD status and other co-morbid conditions that can negatively impact language development. Cognitive and linguistic strengths should be documented alongside weaknesses as these may be used to support language and communication. Throughout development, interventions to increase linguistic competencies should be embedded in socially meaningful contexts, with the goal of improving social interaction and pragmatic language skills. Literacy development will require attention; early oral language programs should have a positive effect on later reading comprehension. It also likely that there will be a need to work with families to decrease inappropriate communication and challenging behaviors.

DLD ASSOCIATED WITH SENSORY IMPAIRMENTS

Visual Impairment

Children with congenital visual impairments (VI) may experience some early delays in the acquisition of language, but by school age these problems are largely resolved (Mulford, 1988). Children with VI may also learn to read with the help of specially adapted writing systems such as Braille and computer programs that convert text to speech. However, pragmatic skills are vulnerable in children with VI and there is increasing evidence that many social-communication behaviors in VI resemble those seen in sighted children with ASD (Tadic, Pring, & Dale, 2010). This section will therefore focus on the nature of these pragmatic deficits and implications for clinical treatment.

Early differences in language acquisition may be attributable in part to disruptions in early visual experiences, for example triadic joint attention. As a result, toddlers with VI are delayed in their acquisition of first words and phrases (Lahey, 1988). Despite these early delays, previous research has consistently demonstrated that children with VI develop age appropriate vocabularies and MLUs by their third birthday (Andersen, Dunlea, & Kekelis, 1984; Landau & Gleitman, 1985). However, use of language may be disrupted; for example, children with VI and their conversational partners may have difficulty understanding each others' referents (Landau, 1997). Other pragmatic impairments include the extensive, and sometimes inappropriate, use of questions; a paucity of communicative gestures; and extensive use of imitative speech, repetitions, and verbal routines (Norgate, Collis, & Lewis, 1998; Preisler, 1991). Tadic et al. (2010) compared children with VI to sighted peers on measures of "structural" language (as measured by the Clinical Evaluation of Language Fundamentals [CELF]) and parent report of pragmatic impairments. On the whole, the groups did not differ on structural language measures, with the children with VI outscoring their peers on the Recalling Sentences subtest, demonstrating good verbal memory. However, on the *Childhood Communication Checklist—2* (CCC-2), children with VI received consistently poorer scores on the semantics scale, the social interaction scale, and all scales of pragmatic functioning (nonverbal communication, inappropriate initiation, coherence, stereotyped language, and use of context). Scores on the CCC-2 were significantly correlated with a checklist screening for ASD, but were not related to structural language scores.

Given these findings, the role of the SLP will likely involve facilitating early social-communicative exchanges between parents and their children with VI. This may involve helping parents to recognize and explicitly comment on and reinforce nonverbal communication behaviors they themselves emit or observe in their children. It will also be necessary to help families find alternative ways of establishing joint attention and using these opportunities to provide rich linguistic stimulation. Some tried and true methods of facilitating language and social communication in this population include:

- Provide labels and descriptions of the objects the child handles and what he or she can do with these objects
- Ask both open-ended and more directive questions
- Provide more qualitative information not only about the child's actions, but also other things going on in the environment
- Model and encourage the child to engage in pretend play
- Engage in shared book reading activities

Such activities will foster strong links between the child's language and the surrounding environment.

Hearing Impairment

Helen was a very bright toddler. At age 2 she was already saying sentences, chatting away to anyone who would listen. She liked to draw and had great fun playing "family" with her dolls. When she was 2½, she suffered a serious bout of meningitis, resulting in hospitalization. Her hearing was tested during her hospital stay, and she was found to have a severe loss in both ears. She was fitted with hearing aids before she returned home. Her parents were distraught that she had permanent hearing damage as the result of her disease, but they were determined to minimize any adverse effects. They made sure she wore her hearing aids at all times and were careful to speak clearly and directly to her only when she was fully attending to them. When she turned 3, they enrolled her in a preschool program that combined hearing-impaired and mainstream children in an intensive language stimulation program. When their physician saw Helen for a follow-up, she discussed the possibility of a cochlear implant to improve Helen's hearing. Her parents spent a great deal of time carefully considering the risks versus the benefits of this treatment option.

Helen has one kind of hearing impairment that can profoundly affect oral communication. Her story is also a powerful reminder that even today, common childhood illnesses can have devastating consequences. Her case also illustrates the crucial role that families can have in influencing the outcome of disorder. Finally, Helen's experiences show us the tough choices families and clinicians often face in selecting the best intervention strategies for a particular child with a hearing impairment. Let's look at some of these issues in a little more detail.

Hearing impairments may be characterized by both degree and type. The degree of hearing loss is defined by the audiometric classification of Bess and McConnell (1981). Their system is provided in Table 4-1. It is based on the pure tone average, or the average threshold a client displays in pure tone testing at the "speech" frequencies of 500, 1000, and 2000 Hz. Helen's audiogram appears in Figure 4-4.

Of course an audiogram alone tells us very little about a child's language competence. In addition to severity of loss, several other factors may influence language outcome: the age at which the hearing loss occurred or was identified, the cause of hearing loss, when and how hearing amplification devices are used, the presence of

TABLE 4-1 Categories of Hearing Loss

Degree of Hearing Loss	Hearing Range (dB SPL)
Normal	–10–15
Slight	16–25
Mild	26–40
Moderate	41–55
Moderately severe	56–70
Severe	71–90
Profound	91+

FIGURE 4-4 Helen's audiogram.

medical conditions, and the child's communication environment (Cleary, 2009). Thus, individualized assessment of language skills and careful consideration of individual needs are necessary to plan the intervention program.

Three types of hearing loss are usually described: conductive, sensorineural, and mixed. Conductive losses result from interference in the transmission of sound from the auditory canal to the inner ear, while the inner ear itself functions normally (Northern & Downs, 2002). Conductive losses are usually treatable and transient. The most common conductive losses in children are associated with otitis media (OM), the inflammation or infection of the middle ear. Hearing loss in relation to OM is usually fluctuating and intermittent. Sensorineural losses result from damage to the inner ear. They can be congenital or result from injury, infection, ototoxicity, or the degenerative effects of aging. They are not usually directly treatable or reversible, although cochlear implants are used to provide one form of surgical intervention. Mixed losses are caused by problems in both the conductive and sensorineural mechanisms. Below we will consider language and literacy development in children with sensorineural and mixed hearing impairments. Then we will briefly consider the impact of OM and conductive losses on language and literacy development. Finally, we will provide an overview of auditory processing disorder (APD). This disorder does not involve perceptual hearing loss, but is thought to result from atypicalities in neural responses to auditory information (ASHA, 2005a).

Sensori-Neural Hearing Loss

Cognitive Characteristics

Before the mid-twentieth century there was a general consensus that children with congenital hearing losses were intellectually disabled and inferior to their hearing counterparts. In the 1960s,

that view was comprehensively challenged (Vernon, 2005). Today of course we know there is no reason to assume that individuals with hearing impairment (HI) will experience intellectual impairments, indeed many children score within the normal range on appropriate tests of nonverbal reasoning. However, like all developmental populations, there is considerable variability. It is also important to remember that approximately 30% of children with moderate to profound losses have additional medical conditions that may adversely affect cognitive development (Fortnum, Marshall, & Summerfield, 2002). However, testing individuals with HI using appropriate measures can be a challenge. Tests such as the Universal Nonverbal Intelligence Test (UNIT, Bracken & McCullum, 1998) do not involve oral language instructions or responses and so may be ideal for assessing this population.

Language Characteristics

Unlike the other disorders we've covered in this chapter, a major consideration for families of children with profound hearing losses will be what language the child will learn and when he or she will learn it. Historically, this has been a contentious issue. Deaf children born to deaf parents are likely to learn American Sign Language (ASL) (or British Sign Language in the UK) and will have exposure to this language from the earliest opportunity. These parents may not view their child's HI as a disorder at all, but rather see themselves and their child as culturally different. Members of Deaf culture do not see the need for hearing aids or cochlear implants because they have developed a rich culture and fulfilling social world for members of the community, with a fully developed language, set of beliefs, and social mores. As clinicians, we must be sensitive to and respect these cultural views, as we would those of hearing clients from culturally diverse backgrounds.

Three issues require further consideration. First, the majority of deaf children are born to hearing parents who do not know Sign and may not even be immediately aware that their child has a hearing impairment. For these children there is a real possibility that early language and communication opportunities will be disrupted, with consequences for later language proficiency and social-cognitive reasoning (Woolfe et al., 2010). A second issue is that even within Signing communities, there are individual differences in language competence. Until recently we have lacked linguistically and culturally appropriate assessment instruments, but that is changing (visit www.dcal.ucl.ac.uk for an overview) and it is now possible to assess at least some aspects of language using Signed tests normed on Deaf populations (Mason et al., 2010). Finally, improvements in universal screening of hearing of newborn infants mean that hearing impairment is now identified at birth. In 2000, the FDA approved cochlear implantation for children as young as 12 months. These two advances mean that many more SLPs will be working with infants and their families to prepare them for cochlear implants (CI). The implications of early implantation and the outcomes for children with CI will therefore be considered.

Form

Not surprising, the early speech sound inventories and patterns of canonical babbling observed in children with HI are different from those of hearing children (Cleary, 2009). However there is enormous variability that is contingent on use of amplification or CI. Once words are acquired, the sequence of phonemes learned is roughly similar to that of hearing children, though protracted in development. There is also some evidence that, in addition to typical phonological processes, children with HI are more likely to produce voicing errors, extra nasality, and initial syllable omission.

Many children with severe and profound hearing losses will have lower levels of speech intelligibility, but again rates vary depending on aids/implantation, listener experience, and topic content. In one study that directly compared intelligibility ratings of speech in CI, hearing aid (HA), and normal hearing (NH) groups, children with CI had intelligibility scores that were indistinguishable from NH peers and significantly higher than ratings for the HA group (Baudonck, Dhooge, & Van Lierde, 2010).

Spoken language morphology and syntax have long been recognized as particularly challenging for children with HI. In the early stages, rate of MLU growth is slower than that seen in NH children (Geffner 1987). Rates of MLU growth in children with CI also appear to be delayed, but group means mask considerable within-group variation (Szagun, 2001). It appears that age of implantation or level of residual hearing can dramatically influence growth; in this case earlier and more are definitely better. In terms of morphological structure, the use of Signed systems of English can be useful in highlighting the sound, spelling, and morphological conventions of English (Cleary, 2009), many of which are perceptually non-salient. However, as we've seen, outcomes are decidedly mixed and many children fail to acquire the typical range of morphemes used in English.

In general, the picture is one of qualitatively similar but substantially delayed acquisition of grammar. There are some notable differences though and it is suggested that children with HI (including CI users) may rely more on semantic/conceptual cues than purely grammatical markers in developing morphology (Ruder, 2004). For instance, like children with primary DLD, children with HI are able to mark plural *-s* with little difficulty but are more likely to omit third person singular *-s*. In terms of grammatical structure, children with HI are prone to omit sentential elements and are significantly delayed in their acquisition of complex grammatical structures (Friedmann & Szterman, 2006). However, as we've seen already, early audiological intervention, and, in particular, CI use in the early preschool years yields marked improvement in language growth approaching 100% of gains seen in the NH population (Niparko et al., 2010).

Content

Like language forms, language content can vary dramatically depending on the situation. Overall, there is some evidence that vocabulary levels may be delayed in HI, but that early CI use can alter the developmental trajectory such that children achieve typical levels of receptive vocabulary (Hayes, Geers, Treiman, & Moog, 2009). A recent study of deaf children exposed from birth to British Sign Language revealed similar growth curves and patterns of vocabulary development, and indicated that predictors of language growth in Signing HI children are similar to those seen in NH populations, namely maternal education and maternal language input (Woolfe et al., 2010). Much less is known about the detailed semantic knowledge of children with HI and the integrity of their semantic networks.

Children with HI are reportedly less successful on experimental tasks of word learning (see Cleary, 2009). Children with HI make the typical inference that a novel label refers to a novel object rather than a familiar one (Lederberg, Prezbindowski, & Spencer, 2000) but have more difficulty labelling new referents and recalling the label after training (Houston et al., 2005).

Use

There is substantial evidence that learning about mental states requires rich conversational experience with others; as such, deaf children born to deaf parents tend to outperform deaf children born

to hearing parents on measures that tap social-cognitive understanding (Woolfe et al., 2002). What is less clear is whether these inefficiencies in social understanding result in difficulties with social interaction or the social use of language. Falkman and Hjelmquist (2006) reported that non-native signers were less successful than hearing peers on referential communication tasks, but that performance was associated with working memory, rather than social cognition. These studies highlight that, in terms of language use, early exposure to language and communication in socially meaningful contexts is more important than hearing status per se. Pragmatic skills have not been extensively researched and clearly more work is needed to characterize the pragmatic abilities of children with different language and amplification experiences.

Literacy

As with spoken language outcomes, literacy outcomes for children with HI have changed dramatically with the introduction of CI. In the past, it was not uncommon to find children with HI leaving school with little functional literacy and reading age equivalent to a NH 9-year-old (Conrad, 1979). It has also been the case that the gap between HI and NH readers has increased over time; a delay of 1 year at age 8 can become a 4-year delay at age 14 (Harris & Moreno, 2004). There is evidence that CI use can result in near normal levels of reading comprehension (Spencer et al., 2003), though others have reported continued deficits in reading and spelling in adolescents with HI (Harris & Terleksti, 2010). Interestingly, Harris and Terleksti (2010) reported that adolescents using HA were better than peers with CI on measures of literacy attainment, though they were still below age expectations. This could be due to the age at which children received CI (average age of 4) but may also reflect differences in educational placement; HA users were more likely to be placed in specialist educational provision, whereas CI users were more likely to be in mainstream classrooms. Johnson & Goswami (2010) explored literacy outcomes in early-implanted versus late-implanted CI users. The early CI users outperformed the comparison group on all measures of reading. Importantly, measures of oral language significantly predicted reading outcome, as did measures of phonological processing.

Another factor that may contribute to literacy development in this population is early exposure to print. The focus on amplification issues and establishment of oral language skills can sometimes mean that less attention is paid to preliteracy skills. Kretschmer and Kretschmer (2001) reported that children with HI exhibit more

Sign language is often used as a communication modality for children with HI.

emergent literacy behaviors when they are provided with engaging, print-rich environments at home and at school, and when their early attempts at writing in these environments are similar in form and content to NH peers. Clearly, exposing children with HI to books and stories, demonstrating the uses of writing in everyday activities, and providing attractive writing materials and opportunities will be useful in this population, as in others, for fostering literacy development.

Implications for Clinical Practice

There is little doubt that cochlear implants have radically changed the expected outcomes for children with severe and profound hearing impairments. There is also little doubt that earlier CI use is associated with better long term outcomes. For example, Niparko et al. (2010) reported that for each year the history of hearing deficit was shortened, there was a significantly steeper rate of increase in language comprehension and production scores. As we've seen, early implantation also yields better literacy outcomes, though literacy remains a challenging area of development for children with HI (Geers et al., 2008). In addition, there is some evidence that delayed exposure to language can alter neurocognitive mechanisms in ways that affect learning. For instance, Conway et al. (2011) reported that children with HI who were CI users were less adept than NH peers at implicitly learning visual sequences. Performance on this task was correlated with language ability, suggesting a potential limitation on the benefits of later implantation.

The net result is that children with HI will be referred to hearing and SLP services at ever earlier ages. Prior to implantation, many infants will be required to undergo a trial period of hearing aid use. The clinician will need to work closely with the family and the audiologist during this sensitive period. Spencer (2009) outlined key issues facing families and professionals. These include maximizing device compliance, exploring communication philosophies and options (i.e., decisions regarding CI and sign language use) and the need for genetic testing. All of this will be occurring within the first year of life, a challenging and emotional time for any new parent! Working with families and infants will involve helping families to recognize and respond to their child's communication attempts, as well as helping them to recognize how their own behavior facilitates language and communication in their child. Once the CI is in place, the clinician will work with families and other professionals to establish treatment goals focused on improving listening skills and responses to new sounds as well as early speech and language goals to foster in a socially meaningful context. Intervention at this early age should pay off in the longer term, though monitoring of children throughout the school years is recommended, with particular focus on developing literacy skills.

Otitis Media

According to the U.S. Department of Health and Human Services, OM is one of the most common diseases of young children. Three quarters of all children experience at least one episode of OM during the preschool years. Children who experience OM, particularly with effusion, often suffer some degree of conductive hearing loss during the OM episode. It has long been thought that such mild, fluctuating hearing losses, when experienced repeatedly during the sensitive period of language development, can have a lasting and negative impact on language learning. Shriberg & Kwiatkowski (1982b), for example, found that one-third of children enrolled in speech-language interventions had a history of recurrent middle ear disease.

Many have questioned this long held assumption. Results such as those reported by Shriberg & Kwiatkowski (1982b) may be influenced

by ascertainment bias; children who attract clinical attention are more likely to experience multiple developmental concerns, of which OM may be one. Of the entire population of children who experience OM though, it may be that all other things being equal, very few have lasting problems with language development. Population studies are required to determine the true risk of OM on language outcomes. A very large population study of more than 6000 preschool children reported weak and largely non-significant correlations between number or duration of OM episodes and later language scores, with sociodemographic variables proving the best predictors of outcome (Paradise et al., 2003). The same study also used a randomized controlled trial in which children with persistent OM were randomly allocated to receive tympanostomy tubes immediately or after a delay. At follow-up, there were no differences between the two groups in general cognitive outcomes or any measure of speech or language. Importantly, no differences emerged over time; at ages 9 to 11 the two treatment groups performed similarly on an extensive battery of cognitive, language, and literacy measures (Paradise et al., 2007). Even when early delays are detected in clinically referred samples, these early differences appear to wash out over time, with typical language status apparent by school age (Zumach et al., 2010).

Thus, in otherwise healthy children, OM does not confer increased risk for long-term language or literacy impairment. However, it is important to remember that many developmental disorders such as Down syndrome are particularly susceptible to OM, which may exacerbate language-learning difficulties. In these populations, hearing should be monitored closely.

Auditory Processing Disorder

APD is a controversial diagnosis that is not currently part of conventional diagnostic systems (e.g., Diagnostic and Statistical Manual of the American Psychiatric Association, DSM-IV) but is increasingly identified in the US, Australia, and the UK. Increasing interest in the disorder led ASHA to issue a position statement in 1996, which was updated in 2005. According to ASHA (2005a) APD may be defined as "the efficiency and effectiveness by which the central nervous system (CNS) utilizes auditory information." AP includes the auditory mechanisms that underlie the following abilities or skills:

- sound localization and lateralization
- auditory discrimination
- auditory pattern recognition
- temporal aspects of audition, including temporal integration, temporal discrimination (e.g., temporal gap detection), temporal ordering, and temporal masking
- auditory performance in competing acoustic signals (including dichotic listening)
- auditory performance with degraded acoustic signals

Part of the controversy surrounding this disorder appears to stem from the methods of assessment and the degree to which they involve speech stimuli (Dawes & Bishop, 2009). When such tasks are included, it is difficult to ascertain the causal connection: is language impaired because of auditory processing disorder, or is performance on the task compromised because of limitations in linguistic ability? Clearly though, many language-based tasks will require the abilities listed above. ASHA (2005a) clarifies the situation to some extent by stating:

although abilities such as phonological awareness, attention to and memory for auditory information, auditory synthesis, comprehension and interpretation of auditorily presented information, and similar

skills may be reliant on or associated with intact central auditory function, they are considered higher order cognitive-communicative and/or language-related functions and, thus, are not included in the definition of AP. (p. 4)

Dawes and Bishop (2009) also point out that 50% of children meeting criteria for APD also meet criteria for other developmental disorders such as ADHD, which may affect performance on diagnostic tests of APD. This reinforces the need for specific measures that are unconfounded by language and/or attentional demands. This also raises issues about APD as a coherent diagnostic entity, or whether the label reflects the conceptualization of the problem by the professional assessing the child (Bishop & Dawes, 2009). In other words, a child with poor attention and language delay may be diagnosed with APD by an audiologist, DLD by a speech-language pathologist, or ADHD by a clinical psychologist. Dawes and Bishop (2009) conclude that there is no evidence that APD is a coherent diagnostic category, but that there is evidence that many children with a range of developmental diagnoses experience problems with auditory processing. The causes and consequences of these auditory difficulties are a matter of debate and much more research is needed to resolve these issues. In the meantime, improving methods of assessment and consensus on diagnosis is a top priority. Critically, measures should be selected that do not involve speech or language stimuli and so do not confound poor performance with poor attention.

Even when a problem is diagnosed, there remains no clear consensus about how this should be managed. Bamiou et al. (2006) highlights the dearth of studies investigating treatment efficacy for APD. These authors further indicate that current clinical practices do not aim to treat the auditory deficit directly, but rather aim to reduce the impact of auditory processing deficits through environmental modification or signal enhancement, such as the use of auditory trainers in classrooms.

Deaf-Blind

Children with significant deficits in both hearing and vision are considered *deaf-blind* even though some may have useful residual vision and/or hearing. There are two major causes of deaf-blindness. One is Rubella syndrome, a congenital condition that arises when the mother contracts rubella, or German measles, during the first months of pregnancy. Thanks to wide-spread immunization for Rubella, deaf-blindness attributable to this syndrome has been greatly reduced. The second major cause is Usher's syndrome (Shprintzen, 1997), a rare genetic disorder.

Because of the multisensory deprivation that children with deaf-blindness experience, Nelson (1998) recommended using contextualized and dynamic assessment techniques to evaluate skills and identify communicative needs in this population. It is worth remembering, too, that although these children have complex and severe disabilities, they may have normal cognition. When accurate cognitive assessment is not available or feasible, it is best to set aside questions of basic intelligence and work to expand conceptual, social, and communicative skill as far as possible. Some form of augmentative and alternative communication (AAC) is almost always useful in these cases. Communication devices that emulate the receiving and transmitting modes of tactile finger spelling have been shown to be useful with this population and activate neural circuitry involved with language processing (Obretenova et al., 2010). Some examples of AAC interventions that may be used with deaf-blind children are outlined in Box 4-1.

BOX 4-1 AAC Intervention Techniques for Children with Deaf-Blindness

UNAIDED TECHNIQUES

- Signalling: simple body signals such as coordinated rocking with reciprocal cues to start and stop
- Gestures: conventional gestures such as hi, bye-bye, or head nods
- Anticipatory cues: cues used to signal an upcoming action so the child may anticipate events, such as rubbing the child's cheek with a washcloth to signal bath time
- Adapted signs: the child's hand can be shaped to produce signs, and the child can be encouraged to feel the clinician's hand shape to perceive signs. At first, gross approximations can be accepted and then gradually shaped to more conventional signing.
- Finger spelling: finger spelling can be introduced by first manipulating the fingers in playful, interactive games. Eventually, familiar objects and actions within routines can be labelled with finger-spelled words.
- Speech: children with residual hearing may be taught speech, but other modes of communication can co-exist with speech instruction.
- Print/Braille: children with significant residual vision can be introduced to print when level of functioning appears appropriate. Braille may be appropriate for those who can make fine tactile discriminations.

AIDED TECHNIQUES

- Opticon: this device changes print to a tactile representation and may assist higher functioning deaf-blind students who rely on Braille for academic instruction.
- Teletouch: this device allows sighted people to type messages on a standard keyboard, so that each letter is reproduced as Braille.
- Communication boards: pictures of symbols can be labelled with Braille or more concrete tactile cues and used for both receptive and expressive communication.
- Typing and writing: computers and dedicated electronic augmentation devices can be used and coupled with speech synthesis software to allow an individual's message to be written out and spoken.

Finger spelling is one means of communication used with students who are deaf-blind.

DLD ASSOCIATED WITH ACQUIRED NEUROLOGICAL DISORDER

Freddie had been a precocious preschooler. In fact, he was so bright that his parents had him tested to determine whether he could enter school a year early. The results of the assessment, copies of which his parents kept and showed to every clinician who saw Freddie later, indicated an IQ in the superior range and very advanced verbal skills. When Freddie was 7, he experienced a series of seizures for no apparent reason. After Freddie was hospitalized several times, including extensive experimentation with drug treatments in order to determine appropriate dosage, the seizures were partially, but not fully, controlled. His parents began to notice that Freddie's speech was beginning to deteriorate; his sentences got shorter and he couldn't think of the words he wanted to use. His concentration was poor and he became increasingly impulsive, so much so that his parents had to lock cabinets and keep dangerous substances well out of reach. Even when the seizures were fairly well controlled, the language and cognitive problems did not go away. His parents struggled for years to find a way to release the real, bright Freddie they had known before the seizures started. They firmly believed that Freddie was just as clever as he had been, but was locked inside his own body. Indeed, his nonverbal IQ scores were age appropriate, but his expressive language was telegraphic and he had severe comprehension deficits. He had a terrible time at school and, eventually, his parents reluctantly agreed to place him in a special educational setting so that his language and learning needs could be met.

As Freddie's case illustrates, acquired brain damage can have severe and long-lasting effects on language, communication, and academic success. In this section, we'll review three types of acquired neurological insult that can result in a DLD, before considering implications for clinical practice.

Traumatic Brain Injury

Traumatic brain injuries (TBIs) can be focal in nature. When they are, they are usually open-head injuries, such as gunshot wounds, and their impact on language development is similar to that described for other focal lesions (see "Focal Brain Lesions"). Closed-head injuries, such as those resulting from blows or collisions, tend to involve diffuse damage, affecting large areas of the brain and are the more common type of TBI in childhood. Road accidents and falls account for the largest proportion of cases, though child abuse is an important consideration, accounting for approximately 10% to 15% of cases (Blosser & DePompei, 2001). Boys are more likely to experience TBI than girls. Immediately following injury, children with TBI experience a great deal of spontaneous recovery. Recent research suggests that age of injury significantly predicts language and literacy outcome, with younger children showing more rapid initial recovery followed by poorer outcomes overall (Hanten et al., 2009). Poor prognosis is also indicated by the severity of injury, as measured the Glasgow Coma Index at hospital admission (Ewing-Cobbs et al., 2006) and by family factors such as socioeconomic status (Hanten

et al., 2009). There is considerable debate as to whether age at injury predicts outcome, with some researchers suggesting that earlier injury results in poorer prognosis and others arguing that injuries that occur later in development may be more debilitating. Comparisons across studies may be difficult due to differences in population ages and injuries, and the measures used to establish outcome. For example, Hanten et al. (2009) used standardized measures of reading comprehension and expressive language to measure outcome in children experiencing TBI between the ages of 4 and 15 years. On these measures, children injured at earlier ages had poorer overall outcomes. On the other hand, Ewing-Cobbs et al. (2006) studied a smaller, more homogeneous group of children injured between the ages of 4 and 71 months and measured outcome using standardized tests of academic attainment some 5 years later. At this age, using these measures, age of injury did not significantly predict outcome, whereas severity of initial injury did. In terms of adaptive outcomes, severe injury earlier in childhood results in poorer quality of life and community reintegration outcomes (Chevignard, Brooks, & Truelle, 2010).

Cognitive Characteristics

Cognitive outcomes after TBI are variable, but are important predictors of language ability and adaptive behavior. For example, Ewing-Cobbs et al. (2006) reported that 48% of children with TBI had nonverbal IQ scores in the bottom 10th percentile. Reduced cognitive ability may affect speed of information processing and pragmatic skills such as narrative and discourse competence (Chapman et al., 2006). Deficits in executive function also may be evident after TBI, with consequent difficulties with attention, concentration, and impulsivity.

Language Characteristics

Gerring and Carney (1992) detailed the language recovery process in the immediate aftermath of trauma. At first, children tend to be mute and may only follow simple commands. Early language productions often reflect the confused state that the child is in and are often dysarthric or nonfluent. Speech may be slow, and prosody may be affected so that speech sounds monotonic and "flat." Swallowing disorders are also common during this phase of recovery. During this period, two types of language patterns may emerge; the first is "sparse language production" in which the child does not initiate communication and will only answer questions with single words or short phrases. The second is "excess speech production" in which the child talks too much and makes tangential statements that are off-topic, irrelevant, and sometimes inappropriate.

From this point, language function can show rapid improvement, even in severe cases, though full recovery of language function is rare (Ewing-Cobbs et al., 2006). Factors that further contribute to language and literacy difficulties are marked impairments in attention and other aspects of executive control, such as working memory, and broader cognitive deficits. In general, sentence repetition and tactile naming are not impaired in individuals with TBI. However, mild deficits in naming, word fluency, and expressive/receptive grammar are probable (Sullivan & Riccio, 2010).

Use

Pragmatic language skills are particularly vulnerable in TBI. Marked deficits in discourse processing are common and may include problems with turn-taking, topic maintenance, generating verbal responses, and understanding the intentions of others (Ewing-Cobbs & Barnes, 2002). More formal assessment of pragmatic language may also reveal difficulties understanding non-literal language, generating inferences, resolving ambiguous messages, and a heavy

reliance on verbatim memory, rather than interpretation, in narrative tasks (see Sullivan & Riccio, 2010, for review).

Literacy

The extent of literacy impairment may depend crucially on the age of injury and the extent to which the child was already literate prior to injury. As with most other disorders, reading comprehension is more likely to be impaired relative to word reading and decoding skills (Hanten et al., 2009). This is perhaps not surprising given that skilled reading comprehension requires many of the pragmatic language abilities known to be impaired in TBI. Oral language deficits may not be the only factor contributing to literacy outcome, however. While word reading *accuracy* may be at the expected level, many children demonstrate reduced reading *fluency* following TBI. Slowed word recognition in connected text may tax already limited memory capacity, further interfering with reading comprehension (Sullivan & Riccio, 2010).

Implications for Clinical Practice

As Freddie's story demonstrates, often the hardest thing for families and teachers to accept after an acquired brain injury is that, in many ways, they are dealing with a different person than the one they knew before the neurological damage took place. Both the child and the adults may feel confused and frustrated that things that came easily before seem impossible now. The child may seem to be less compliant, to be "lazy" or unmotivated, to be scattered and inattentive, to have a different personality entirely. Freddie's family's response exemplifies this problem. They keep trying to find the "old" Freddie, and think that, if only they could get the right kind of help, they'd "unlock" him. One challenge for clinicians therefore is to work with families to deal with the Freddies as we find them today, enabling them to establish the maximum levels of functional skill and independence.

Assessment Needs

Identifying a child's stage of recovery from brain injury can be important for assessing needs and planning programs. Blosser and DePompei (2001) suggested that there are three stages to the assessment process in this population:

Phase I: the child is recovering medically, usually in an acute-care facility

Phase II: the child is medically stable and ready to begin rehabilitation

Phase III: ongoing assessment is needed in the child's educational and daily living settings

During phase I, assessment will focus on the physical care needs that affect treatment, such as respiratory, swallowing, or motor control problems. This also is a time to collect case history data from the family about premorbid functioning—the child's communication and academic strengths and weaknesses prior to the accident—and to help families understand the child's current condition. In phase II, assessment focuses on determining the child's functional strengths and needs in behavioral, cognitive, and communicative domains. Phase III entails using formal and informal methods, as we discussed in Chapter 2, to establish baseline functions, identify goals for intervention, and evaluate change in the therapy program. Hotz et al. (2009) provide an overview of a criterion referenced assessment that is currently being standardized for use with this population. The Pediatric Test of Brain Injury has ten subscales and is designed to assess neurocognitive, language, and literacy abilities that are relevant to the school curriculum of children and adolescents recovering from brain injury. As the child continues to recover, it will also be important to include assessment

of higher level language functions known to be vulnerable in children with TBI.

During Phase III, an assessment of the child's environment will also be necessary, in order to identify the demands and expectation of the child's daily living situations (Blosser & DePompei, 2001). This assessment can be used to develop a profile of the most important environmental requirements that should serve as the focus for treatment. For example, it may involve helping to sensitize communication partners to the child's needs and eliminating barriers in the environment to successful communication. Apparently good performance on a standardized test may not translate into effective communication in everyday environments because standardized test procedures provide support that helps children compensate for the impairments in executive functions that frequently disrupt performance in less-structured settings. Looking at language competence in both structured and more unpredictable settings will give us a broader picture of the client's abilities (Sullivan & Riccio, 2010).

Finally, clinicians will need to take account of the child's premorbid levels of functioning in developing assessment and treatment plans, something that is unique to this population. Assessment in the rehabilitation setting should include obtaining school records and discussing the child's academic status with teachers and parents. Skills in which the child was very proficient before the injury could provide good targets for retraining, because overlearned skills may be better preserved. However, inconsistent performance is a hallmark of TBI; we can't assume that just because the child was able to do long division before the injury he or she will be able to do simpler arithmetic problems post-injury. Assessment principles and specially designed tools for children with TBI are outlined in [Box 4-2](#).

Intervention Issues

As we've seen with most of the disorders reviewed in this chapter, developing an intervention program with TBI will involve close collaboration with both families and the multidisciplinary team managing the child's care. In TBI, interventions can be divided into two classes: those that seek to retrain or develop cognitive skills, and those that teach compensatory strategies (Semrud-Clikeman, 2010). Application of these approaches is likely to depend on the phase of recovery the child is in. Unlike other disorders, in the early stages of recovery, the setting for intervention is likely to be in a hospital or rehabilitation setting, and the medical needs of the child at this stage will obviously place constraints on the nature of therapy offered. At this time the child is also in a period of spontaneous recovery and the goal of intervention will be to improve levels of residual function maximally. Sessions should be short and aimed at stimulating one modality at a time, with tactile and motor stimulation preceding visual and auditory stimulation. Once a response to stimuli has been established and is more reliable, more functional activities can be introduced. These may involve physical response (nodding or other nonverbal gesture) to questions aimed at orienting to the child to his or her current circumstances (i.e., date, time, place), basic self-care, and simple visual motor activities.

Once the child has moved into Phase II, intervention should emphasize structured tasks. Because of frequent difficulties with attention, concentration, and impulsivity in TBI, the context of these activities should be free of distractions, repetitive, predictable, and intrinsically rewarding. Their goal would be to develop functional and adaptive behaviors, and may include work on language comprehension, simple verbal problem solving, and the use

BOX 4-2 Assessment Strategies for Traumatic Brain Injury Using WHO (2001) Framework

IMPAIRMENTS IN BODY STRUCTURE AND FUNCTION

- Use standardized tests to examine all major areas of cognitive and communicative functioning
 - Intelligence
 - Executive function
 - Judgement and reasoning
 - Problem solving
 - Attention and concentration
 - Memory
 - Perceptual and perceptual motor skill
 - Academic achievement
 - Speech
 - Language form and content
 - Language use (pragmatics)
- Systematically manipulate test variables to identify factors that influence success or failure on standardized tests

ACTIVITIES AND PARTICIPATION

- Use structured assessment/observations of individual performing functional activities
- Obtain informant data, such as interviews and rating scales (e.g., *Vineland Adaptive Behavior Scales—II*, Sparrow, Cichetti and Balla, 2005)
- Identify successful/unsuccessful participation in real-world activities
- Systematically explore factors that influence performance on everyday activities, including possible compensatory strategies

CONTEXTS AND ENVIRONMENTS

- Document the cognitive and communicative demands of everyday environments (e.g., “curriculum based assessments”)
- Evaluate the communication and support abilities of relevant people in the child’s environment
- Systematically manipulate environmental factors, including supports/behaviors of key communication partners, to identify context-specific features that support successful participation

Adapted from Turkstra et al. (2005). Practice guidelines for standardized assessment for persons with Traumatic Brain Injury. *Journal of Medical Speech-Language Pathology*, 13, 2, pp. ix-xxviii. Available at: www.ancds.org/pdf/articles/Turkstra_Standard_classes.pdf

of self-monitoring to detect and self-correct errors or request clarification from others when needed.

In phase III, the child will be returning to home and school and the clinician will need to work more closely with school staff to facilitate the child’s transition back to the learning environment. Here, the clinician may serve in a consulting role, helping the classroom teacher reintegrate the student into the mainstream program, as well as providing collaborative lessons that focus on integrating communication skills within class lessons. For children with more severe DLD following a TBI, the clinician may need to provide an individualized language program, as well as consulting with education staff to ensure generalization of skills learned in therapy sessions to the classroom environment. Semrud-Clikeman (2010) has provided some suggestions for helping students with TBI reintegrate into the school setting, summarized in Box 4-3.

Intervention may focus on developing metacognitive strategies, or retraining clients to use executive control to monitor their own cognitive processes and regulate learning behavior; many strategies for this population are similar to those we will use for children with language-learning disorders. Table 4-2 summarizes some similarities and differences between these two conditions. We’ll talk much more about developing metacognitive and other learning strategies in later chapters; many of the techniques we use to develop these skills with children who have more specific DLDs, children with ASD or ADHD, will be appropriate to use with children who have experienced TBI. In addition, language use is most likely to be disrupted in individuals with TBI and therapies that target pragmatics and social language use may also be appropriate to use with this population. However, it is always important to bear in mind that children with TBI will have particular learning needs that are not always present in other disorders and that these will need to be taken into account when adapting therapy approaches. These may include: more marked memory deficits for recent events, potential for physical impairments (paresis or weakness), cognitive impairment, poor retention of new information, visual deficits, rapidly changing behavior, internal as well as external distractions, adverse effects on learning due to trauma-induced sluggishness or medication, reduced insight into his or her own learning problems, and labile and sometimes unpredictable emotions not always linked to immediate context (Blosser & DePompei, 2002; Semrud-Clikeman, 2010).

Focal Brain Lesions

Lesions that are focal, or localized to a specific area of the brain, are usually caused by cerebrovascular accidents (CVAs) such as strokes, and are relatively rare in children; however, children with congenital heart defects are particularly vulnerable to CVAs and premature babies may suffer focal damage as a result of intracranial bleeding during their first weeks of life outside the womb. A body of work by researchers in San Diego has prospectively followed the developmental trajectories of language and cognition in children with focal lesions, considering outcomes in relation to side and site of lesion and developmental timing of lesion (Bates, 2004; Dick et al., 2004; Reilly et al., 2004; Wulfeck et al., 2004). These studies revealed remarkable language plasticity in the developing brain and suggested altered developmental trajectories. These were characterized by early delays in word comprehension and gesture (though deficits are more likely following right hemisphere lesions than following left hemisphere lesions) and delays in word and sentence production (though these deficits were more pronounced if lesions occurred in left temporal brain regions, as opposed to more frontal areas). These delays were followed by rapid acceleration of language function such that, by school-age, children with focal lesions were largely indistinguishable from typical peers on measures of vocabulary, grammar, tense-marking, and narrative production (Bates, 2004; Reilly et al., 2004; Wulfeck et al., 2004). More recent studies have suggested that, although language performance on standardized tasks may be within normal limits, children with early left hemisphere lesions may have subtle deficits in language processing relative to peers (Raja et al., 2010) and that measures of narrative may be particularly sensitive to subtle language differences (Demir, Levine, & Goldin-Meadow, 2010). With regard to narrative, Demir et al. reported that children with early focal lesions produced shorter stories that were structurally less complex, used less diverse vocabulary, and made fewer

BOX 4-3 Reintegrating Students with Traumatic Brain Injury into the Classroom*

- Plan small group activities to help develop interaction skills
- Clarify verbal and written instructions by reading written instructions out loud and accompanying verbal instructions with written ones. Repeat and paraphrase often, define unknown terms
- Explain core vocabulary and concepts; pre-teach this information in individual sessions
- Pause when giving instructions to allow extra processing time
- Give the student extra time to respond, since processing speed may be slow
- Avoid figurative language, or explain it when used
- Give the student a classroom “buddy” to help him or her keep on top of instructions, assignments, and classroom transition times
- Let the student use assistive devices, such as a computer or iPad
- Help the student “get organized” by having him or her keep a written (or computer based) log of classes, assignments, due dates, etc.; monitor the log regularly
- Set aside time for the student to talk to a trusted adult about feelings and frustrations
- Plan extracurricular activities based on interests before the injury as well as on current abilities
- Avoid direct, confrontational questions in class; ask leading or indirect questions (“tell me about . . .”) to encourage responsiveness
- Decrease distractions in the classroom; if mobility problems are present, carefully arrange classroom furniture to allow freedom of movement
- Modify assignments by reducing the number of questions to be answered, or material to be read; let student record lectures, give test answers verbally to a scribe; go over tests and explain answers
- Augment textbooks with pictures and vocabulary lists, highlight key information; provide a “podcast” with a summary of textbook information; assign review questions and use reciprocal teaching techniques
- Teach compensatory strategies
- Announce and clarify conversational/lesson topics
- Support communication with gesture, pictures, print, etc.
- Require and expect communication, reinforce all communicative attempts; construct opportunities to communicate (e.g., lunch buddies, paired classroom activities)
- Practice higher level reasoning skills in small groups with peers engaged in problem-solving activities
- Encourage memory skills by teaching strategies such as categorizing, association, rehearsing, visualizing, and chunking

*Adapted from Semrud-Clikeman (2010). Pediatric traumatic brain injury: Rehabilitation and transition to home and school, *Applied Neuropsychology*, 17(2), 116-122.

inferences regarding the cognitive states of the story characters. These deficits occurred despite the fact that the children with focal lesions did not differ from the comparison group on standardized measures of grammar and vocabulary. Thus, most children with focal lesions make more or less complete recoveries in terms of speech, language, and communication, though the clinician should be alert to subtle deficits in higher-level language tasks that may interfere with academic achievement.

Seizure Disorders (Landau Kleffner Syndrome)

Some children, like Freddie, go through a period of normal development, then suddenly or gradually lose language skills in association with a seizure disorder. Landau-Kleffner syndrome (LKS), also known as acquired epileptic aphasia, is a rare seizure disorder that causes severe language disorder. Onset is usually between 3 and 6 years of age, though it can occur any time in childhood. It is often misdiagnosed because overt epileptic seizures are uncommon. The typical clinical picture is of a child who loses language skills rapidly after a period of normal development, and comprehension is usually most severely affected. The difficulties in language understanding are variable; some children may be able to understand single words or short phrases but others may no longer understand any spoken language, not even their names. Deafness may be suspected, but ruled out after a hearing test is conducted; the problem is not with hearing, but with making sense of the auditory input. Difficulties with comprehension often occur along with difficulties speaking. In the most severe cases, children may lose

speech altogether and may resort to gesture to convey meaning. Selective mutism may therefore also be considered given the child's history of verbal communication. However, in the case of LKS, there is a genuine loss of language. While the language impairment may be relatively circumscribed with nonverbal cognitive abilities intact, LKS may be associated with behavioral difficulties and stereotypes that resemble autism and may further confuse the clinical picture (Deonna & Roulet-Perez, 2005). Thus, when a child presents with severe comprehension deficits and language regression, referral to a pediatric neurologist is warranted so that a sleep electroencephalogram (EEG) may be carried out in order to demonstrate EEG abnormalities.

All children with LKS have language disorders and will require assessment and support from the speech-language pathologist. Prognosis is more optimistic for children in whom onset occurs after the age of 6, after language has been established. However, outcomes for children with onset in the preschool years are particularly poor and significant language deficits may persist into adulthood. Pharmacological treatments may be effective, and there is some evidence that early diagnosis and prompt medical intervention is important for improved prognosis, but outcome is variable and controlled clinical trials are lacking (Mikati & Shamseddine, 2005). When language has regressed and comprehension deficits persist for more than a few weeks it is essential to provide children with alternative means of communication, such as Sign language, which can be used in conjunction with verbal language (Deonna et al., 2009). Some children with LKS may develop problems with behavior and social interaction that are similar to autism spectrum behaviors (Deonna & Roulet-Perez, 2010). For these children, an emphasis on developing social

TABLE 4-2 Differences Between Language-Learning Disabilities and Acquired Language Disorders

Language-Learning Disability	Acquired Language Disorder
1. Mild memory problems	1. Severe, recent memory problems, with difficulty carrying over new learning
2. Early onset	2. Later onset
3. Central damage can only be assumed from "soft neurological signs"	3. Direct evidence of neurological impairment
4. No pre/post contrast	4. Marked pre/post contrast of abilities, self-perception, and perception of self by others
5. Skills and knowledge show uneven development	5. Some old skills and knowledge remain, but there are inconsistencies of performance
6. Physical problems usually include only mild motor uncoordination	6. Physical disabilities may include paresis (weakness) or spasticity
7. Basic cognitive skills may be intact	7. Basic cognition is commonly disrupted
8. Acquisition of new skills is slow, but what is learned is usually retained	8. What is learned may not be retained; much repetition and practice using compensatory strategies are needed
9. Status changes slowly	9. Status may change rapidly during recovery
10. Visual perceptual problems often unaccompanied by visual impairment	10. Visual problems often include double vision, poor depth perception, inability to adjust from near (book) to far (black-board) vision, partial loss of vision
11. Client is distracted by external events	11. Client is distracted by both external and internal events, with internal events related to the brain damage
12. Normal or high activity level	12. Recovery from coma may include slowness or lethargy
13. Seizure medication, which can cause dulling of cognitive function, used only if frank seizures are present	13. Seizure medication may be used to prevent seizures, even if they have never occurred, and their cognitive dulling effects may influence learning
14. Usually aware of own learning problems	14. Injury may cause lack of awareness of learning problems in some cases
15. Behavior modification strategies are often effective	15. Organic dysfunction and memory losses may decrease the success of behavior modification
16. New learning can often be linked to past learning, although memory problems are present	16. Loss of some long term memory may make linking new learning to old more difficult
17. Emotional reactions connected with present situation	17. Emotions can be labile and unpredictable and may not be linked to immediate situation

Mini-seminar presented at the annual convention of the American Speech-Language-Hearing Association, San Antonio, TX; Blosser, J., and DePompei, R. (2002). *Pediatric traumatic brain injury* (2nd ed.). San Diego, CA: Singular Publishing Group.

communication skills, imaginative play, and emotional understanding of self and others may be high priorities. Developing language and conversational skills in everyday social settings is also recommended.

In LKS, visual processing is still relatively normal and can therefore be used to support oral language. In addition to Sign language, symbol systems may be used for communication, or to provide visual cues to help structure the learning environment (i.e., classroom and therapy timetables). Reading may also be possible, though children acquiring literacy after LKS may benefit more from whole word strategies as opposed to more typical phonics based approaches (GOSH NHS Trust, 2010).

DLD ASSOCIATED WITH PSYCHIATRIC DISORDERS

Language disorders have long been associated with risk for psychiatric disorder; an early population study in Canada indicated that preschool language impairment was a strong predictor of psychiatric outcome in the middle school years, with ADHD and emotional disorders the most common psychiatric diagnoses (Beitchman et al., 1996). Convergent evidence from child psychiatry clinics indicates that approximately one-third of children referred for assessment of socio-emotional disturbances may have previously undiagnosed

language impairments (Cohen, Barwick, Horodezky, Vallance, & Im, 1998). When combined with children whose language impairments had already been identified, some 50% of school-aged children referred to psychiatric clinics have significant language difficulties (see Im-Bolter & Cohen, 2007, for review). Although there is little doubt that rates of co-morbidity are higher than would be expected in the general population, there is much debate surrounding the causal relationships between DLD and psychiatric disorders such as ASD and ADHD. It would seem likely that at least some of the genetic factors that confer risk for language impairment are shared across developmental disorders; a prudent approach would therefore be to assess language functioning in any child referred for psychiatric evaluation, even if behavior is the primary presenting complaint.

Autism Spectrum Disorders

ASD is an umbrella term that encompasses a range of disorders that are characterized by core impairments in social communication and a restricted repertoire of interests and behaviors (APA, 2010). In the past, terms such as Asperger syndrome, pervasive developmental disorder-not otherwise specified, autism, and autistic disorder all came under this umbrella. However, the most recent revision to the Diagnostic and Statistical Manual of the American

Children with ASD have difficulty developing communication skills.

Psychiatric Association (DSM-V; APA, 2010), is recommending abolishing these labels in favor of one diagnostic term: ASD. Changes to the core symptom structure and the introduction of severity criteria, to help families and practitioners make sense of where a particular child sits on this very broad spectrum, are outlined in [Boxes 4-4](#) and [4-5](#).

Leo Kanner (1943) first described 11 case studies of children with this disorder, highlighting profound social disturbances, qualitative differences in language development and language use, and remarkably good memory for details and rote learning (see Donovan & Zucker, 2010 for a fascinating account of the life of Donald T, the first case study: www.theatlantic.com/magazine/archive/2010/10/autismand8217s-first-child/8227).

Kanner suggested a biological basis for the disorder, but also remarked that the most of the mothers of these autistic children had

university educations (unusual at the time) and that the disorder might at least partially result from the care received by these “refrigerator” mothers. It took years of grassroots efforts on the part of devoted parents, and research that demonstrated that parents of children with ASD are no different from parents of other children with disabilities (Anderson & Hoshino, 2005; Volkmar, Carter, Grossman, & Kline, 1997) to dispel this myth. Today we know that ASDs are strongly influenced by complex genetic risk factors that alter neurobiological development (Abrahams & Geschwind, 2010). Parents are important people because they can positively influence the language and communication development of their children, but are in no way responsible for causing the disorder.

Of all the developmental disorders we’ve talked about, ASD is probably the most deeply researched, and the most variable in terms of cognitive profile, language ability, co-morbid diagnoses, and eventual outcomes. This variability makes it extremely difficult to identify proximal causes of disorder, and especially challenging to develop and evaluate treatment approaches for this population. The descriptions that follow will give you a flavor of this heterogeneity and highlight some key cognitive and language characteristics of children with ASD. However, it is important to remember that, for this population, as with many others we’ve talked about so far, differences between children are as striking as the similarities and an assessment or intervention approach that works well with one child may be completely inappropriate for another child with the same ASD diagnosis.

Early Communication

There is increasing interest in identifying the earliest signs of autism in infancy. A research strategy that has really taken off in the last few years is to recruit babies who are at genetic risk of developing ASD, by virtue of having an older sibling with the disorder (Elsabbagh & Johnson, 2010; Tager-Flusberg, 2010). These studies have yielded

BOX 4-4 Diagnostic Criteria for Autism Spectrum Disorders

Rights were not granted to include this box in electronic media.
Please refer to the printed publication.

BOX 4-5 Severity Levels of ASD*

SEVERITY LEVEL FOR ASD	SOCIAL COMMUNICATION	RESTRICTED INTERESTS AND REPETITIVE BEHAVIORS
Level 3 "Requiring very substantial support"	Severe deficits in verbal and nonverbal social communication skills cause severe impairments in functioning; very limited initiation of social interactions and minimal response to social overtures from others.	Preoccupations, fixated rituals, and/or repetitive behaviors markedly interfere with functioning in all spheres. Marked distress when rituals or routines are interrupted; very difficult to redirect from fixated interest or returns to it quickly.
Level 2 "Requiring substantial support"	Marked deficits in verbal and nonverbal social communication skills; social impairments apparent even with supports in place; limited initiation of social interactions and reduced or abnormal response to social overtures from others.	Rituals and repetitive behaviors (RRBs) and/or preoccupations or fixated interests appear frequently enough to be obvious to the casual observer and interfere with functioning in a variety of contexts. Distress or frustration is apparent when RRBs are interrupted; difficult to redirect from fixated interest.
Level 1 "Requiring support"	Without supports in place, deficits in social communication cause noticeable impairments; difficulty initiating social interactions and demonstrates clear examples of atypical or unsuccessful responses to social overtures of others; may appear to have decreased interest in social interactions.	RRBs cause significant interference with functioning in one or more contexts. Resists attempts by others to interrupt RRBs or to be redirected from fixated interest.

*APA (2010) proposed criteria as of 1/26/2011.

some surprising findings; for the most part, within the first year of life infants who later receive a diagnosis of ASD are indistinguishable from low-risk peers in terms of social behavior (Rogers, 2009). Instead, subtle differences in motor development, visual attention, and interest in objects may be the earliest signs of atypical development, though these behaviors may be markers of other developmental disorders as well. However, sometime between the end of the first year and the child's second birthday, differences in social interaction behaviors become more apparent and some children show signs of regression (Ozonoff et al., 2010). These aberrant social behaviors include reduced eye contact, social smiling, social interest, and social imitation, reduced response to their own name and fewer responses to bids for joint attention (see Tager-Flusberg, 2011, for review). This combination of social behaviors often co-occurs with delays in gestural communication and language, though some children appear to develop language typically and then experience regression of those language skills (Pickles et al., 2009). These studies suggest that by the first year, infants at high risk for autism are developing in a way that limits opportunity for language development in social interaction contexts. A failure to develop joint attention may be particularly detrimental to language acquisition (Mundy, Sullivan, & Mastergeorge, 2009).

Cognitive Characteristics

The popular media often depicts individuals with ASD as possessing super abilities in skills such as music, math, or drawing. Unfortunately, individuals with these "splinter skills" form a minority of the ASD population, and, as many parents will tell you, these amazing abilities rarely contribute to better academic or adaptive outcomes. The more typical picture is that many children with ASD also have ID, with 50% to 70% of children with ASD obtaining scores on nonverbal IQ measures of less than 70 (Matson &

Shoemaker, 2009). Increasingly, ASD is diagnosed in children with IQ ranges in the average (28%) or above average range (3%) (Charman et al., 2011). While IQ is a good indicator of prognosis, in that those with lower overall cognitive abilities tend to have less favourable outcomes (Howlin, 2005), two issues should be borne in mind. First, very low IQ often occurs in the context of a co-morbid disorder that may also adversely affect outcome. Second, high IQ scores do not always predict outcome; recent studies have found poor correlations between IQ and academic achievement (Estes et al., 2010) or adaptive behavior (Charman et al., 2011).

Numerous cognitive theories have been put forward in an attempt to explain the core behavioral features of ASD. None have directly attempted to explain variation in language skill, though cognitive deficits in these areas would likely have a negative impact on language development and language processing. As in many other disorders we've seen, executive functions (EF) are very often impaired in children with ASD, though working memory may be an area of strength. Intriguingly, measures of EF do not always neatly map on to the symptom profile we'd expect; for example, problems with cognitive flexibility are clearly an issue for many individuals with ASD, and should be related to restricted interests and rigid behaviors. However, correlations between symptom profiles and standardized measures of EF are disappointingly low (Geurts, 2010). Weak central coherence (Happé & Frith, 2006) has been put forward as an explanation of cognitive differences seen in ASD. For example, success on measures of visual processing that require attention to detail in the context of poor integrative functioning are often seen. Problems integrating information in context could lead to many problems with discourse processing, though other explanations have also been put forward (cf. Norbury, 2005). Finally, deficits in social cognition, or in understanding other minds, are the most well known and

well supported cognitive deficits that distinguish children with ASD from children with other developmental disorders. Problems understanding the intentions of speakers have also been explicitly linked to problems learning new words (Parish-Morris et al., 2007) and understanding non-literal language (Martin & McDonald, 2004).

Recent evidence from twin studies has suggested that there is unlikely to be a single cognitive impairment that can explain the range of strengths and deficits observed in ASD (Happé, Ronald, & Plomin, 2006), though few studies have taken a developmental approach to exploring the relationships between areas of cognitive development, and how they influence one another, over time (Pellicano, 2009). The clinician should therefore be aware of the different cognitive challenges that may be present when making assessment and intervention plans for children with ASD, as these additional impairments may influence task performance.

Language Characteristics

Structural language skills are extremely variable in ASD. The range of abilities across all age groups extends from nonverbal to verbose; it is not unusual to find standardized scores on verbal measures spanning 50-70 points even within the same study (cf. Toichi & Kamio, 2003). Another important finding from recent longitudinal research suggests that a significant percentage of children with minimal language skills in early life develop at least some spoken language skills by the age of nine (Lord, Risi, & Pickles, 2004), with only 9% of children remaining nonverbal in later childhood (Hus, Pickles, Cook, Risi, & Lord, 2007).

The degree of language variability within the autism spectrum has led some to question whether there are distinct subgroups of children with ASD, who may be distinguished by different “neurocognitive phenotypes” (Tager-Flusberg & Joseph, 2003). Remember that a phenotype is the set of observed characteristics that are associated with a particular genetic profile; “neurocognitive” suggests that particular patterns of brain development and cognition may also be associated with a particular genetic profile. Tager-Flusberg et al. (cf. Tager-Flusberg, 2006) have argued there are at least two distinct phenotypes within ASD, an Autism Language Normal (ALN) phenotype, in which language form is unimpaired and typical patterns of neuroanatomical asymmetry are observed, and Autism Language Impaired (ALI), in which language form impairment is seen in association with anomalies in left hemisphere brain structure and function (De Fosse et al., 2004). The degree to which ALI and more specific DLDs overlap at behavioral, cognitive, neurological, and genetic levels is a matter of intense debate (Tomblin, 2011). For our purposes, the underlying source of this variability matters less than our knowing that in addition to the social, cognitive, and behavioral challenges a child with ASD may face, a large percentage of children with ASD (approximately 47%, Loucas et al., 2008) will have additional impairments in phonological processing and grammar that resemble non-autistic children with more specific DLDs.

Form

One consistent finding in the autism literature is that, once some verbal language is acquired, articulation of speech sounds is relatively unimpaired across language phenotypes (Kjelgaard & Tager-Flusberg, 2001; Jarrold et al., 1997). However, performance on more complex tests of phonological processing is less clear-cut. Numerous investigators have reported that a significant proportion of children with ASD perform poorly on measures of nonsense word repetition, which taps phonological short-term memory

(Bishop et al., 2004; Kjelgaard & Tager-Flusberg, 2001; Tager-Flusberg, 2006; Tager-Flusberg & Joseph, 2003; Whitehouse et al., 2008). Other aspects of phonological processing appear to be more universally challenging for individuals with ASD. For example, performance on more meta-linguistic tasks of phonological awareness, such as rhyme awareness, is very poor (Nation et al., 2006). In addition, atypical patterns in processing speech prosody are seen across the range of speakers with ASD from childhood to adulthood (Peppe et al., 2007; Shriberg et al., 2001), though these may be more prominent at the sentence level than at the level of an individual word (Jarvinen-Pasley, Peppe, King-Smith, & Heaton, 2008). Finally, although sound substitutions are rare, distortions of speech sounds and voicing patterns have been noted to affect intelligibility in adult speakers with ASD (Shriberg et al., 2001).

Relative to phonology and lexical knowledge, deficits in morphosyntax and grammar are more pronounced for children with ASD in general (Landa & Goldberg, 2005) and for those with the ALI phenotype in particular. Children with ASD use fewer grammatical morphemes than non-ASD peers to mark verb tense and agreement (Roberts et al., 2004), though errors of commission are rare (Eigsti, Bennetto, & Dadlani, 2007; Roberts et al., 2004). Analyses of spontaneous language samples indicate that many children with ASD produce short and grammatically simple sentences relative to non-ASD peers, despite producing equivalent numbers of utterances (Eigsti et al., 2007). More structured tasks involving sentence repetition also reveal poorer performance for individuals with ALI (Norbury et al., 2009; Riches et al., 2009), highlighting the utility of this task as a marker for language impairment in ASD. Impaired sentence comprehension is particularly striking in ALI (Loucas et al., 2008), though studies exploring comprehension of particular syntactic structures are lacking.

Content

At the broadest level, vocabulary scores are consistently depressed in a large proportion of children with ASD across a number of studies, relative to typically developing peers (Kjelgaard & Tager-Flusberg, 2001; Norbury, 2005; Loucas et al., 2008; Lindgren et al., 2009). On the other hand, for a substantial minority of individuals with ASD, receptive vocabulary is considered to be a “peak of ability” (Mottron, 2004). However, what these children know about the words in their vocabularies may be qualitatively different relative to typical peers. For example, Norbury, Griffiths, and Nation (2010) found that children with ASD, matched to a comparison group on both raw scores and standard scores of the British Picture Vocabulary Scales (BPVS), scored more than 1 SD below the comparison group on a measure of verbal definitions. Other investigators have suggested that, in general, the underlying organization of the semantic system in ASD is atypical and impoverished. For instance, individuals with ASD show reduced priming effects for semantically related words (Kamio et al., 2007) and do not use semantic information to facilitate encoding and recall (Bowler et al., 1997; Tager-Flusberg, 1991). However, the findings of many of these studies are somewhat hampered by large within group variation and have failed to distinguish semantic profiles within ASD that might align with specific neurocognitive phenotypes.

Use

Pragmatic deficits are universal within ASD (Tager-Flusberg, Paul, & Lord, 2005) and may be particularly evident in higher level discourse processing and narrative tasks. Individuals with ASD have significant deficits in conversational skill (Adams et al., 2005; Hale & Tager-Flusberg, 2005; Nadig et al., 2010; Paul et al.,

2009), demonstrating either too many or too few initiations, poor topic maintenance, fewer contingent conversational responses, and non-contextual or socially inappropriate utterances. Such deficits are also evident in narrative tasks with ASD individuals producing higher proportions of contextually irrelevant propositions (Norbury, Gemmell, & Paul, 2011), poor referencing throughout the narrative (Diehl et al., 2006; Losh & Capps, 2003; Norbury & Bishop, 2002), and ignoring the motivations of characters or events (Tager-Flusberg, 1995). Understanding of language in context is regarded as particularly problematic for individuals with ASD as evidenced by poor understanding of figurative and metaphorical language (Happé, 1997; Norbury, 2004, 2005), poor inferencing skills (Jolliffe & Baron-Cohen, 2000; Norbury & Bishop, 2003), and reduced ability to resolve ambiguous language (Happé, 1997; Norbury, 2005). Few studies have explored the extent to which language-based pragmatic deficits align with core language profile; those that do so report that children with ALI are more likely to have difficulties with higher level pragmatic language skills than ALN peers (Hoy et al., 2004; Norbury, 2005).

Literacy

Given the pronounced difficulties with social-interaction and oral language development experienced by many children with ASD, it is perhaps not surprising that much less attention has been paid to the reading abilities of children with this diagnosis. Early reports centered on the surprising abilities of some young children with ASD to read words given limited verbal and cognitive abilities. Such children were given the label “hyperlexia,” and there is continued debate over the definitions of hyperlexia and the extent to which hyperlexic reading profiles are specific to ASD, or may occur in other developmental disorders (Grigorenko, Klin, & Volkmar, 2003; Nation, 1999). More recent investigations have revealed much more varied reading patterns in larger cohorts of children with ASD; for example, Nation et al. (2006) found that approximately 30% of the children with ASD they studied were impaired on both word and non-word reading measures, while most of the children had deficits in reading comprehension. Norbury and Nation (2011) found that, although younger children with ASD and good oral language skills had age-appropriate word reading abilities, standard scores reduced over time such that significant differences between individuals with ASD and their typically developing peers were evident by adolescence. One possible reason is that many of these children had reading comprehension difficulties and so, as they grow older, may not have been able to use written text to learn new words to the extent that their peers could (Cain, Oakhill, & Elbro, 2003).

In most of the disorders we’ve talked about, you’ll have noticed strong links between oral language skills and aspects of reading; those with poor phonological skills tend to have problems with decoding text (i.e., non-word reading and spelling), while those with poor semantics and grammar tend to have greater difficulty with reading comprehension. In ASD, those links are not quite so strong. Norbury and Nation (2011) divided an ASD cohort into different language phenotypes (ALI and ALN); though the ALN children as a group had better literacy skills than the ALI group, there were children in each group who had difficulties with word/non-word reading and children in each group with above average performance. In addition, despite age-appropriate language scores, children in the ALN group were not as skilled as typically developing peers in making inferences and monitoring their reading comprehension. It would seem that, in addition to language, aspects of autistic cognition may also influence literacy development. For

example, most stories require the reader to draw inferences about characters’ mental and emotional states in order to understand why they do the things they do. Skilled readers are also required to maintain this narrative thread over hundreds of pages, integrating information across text and with their own experiences and world knowledge. Finally, skilled readers recognize when a passage does not make sense or cohere with what they’ve been reading, and have strategies for recovering uncertain meaning. All of these are skills most people employ effortlessly when reading and yet are likely to pose significant challenges for readers with ASD.

Implications for Clinical Practice

Special considerations for assessment and intervention with ASD are considered throughout this text. Here, we will only stress that, as with hearing impairment and cochlear implants, there is considerable effort now to identify children with ASD at younger ages, so that appropriate interventions and family support can be put in place. There is some evidence that early intervention works (Sutera et al., 2007), but evidence for interventions in infancy are currently lacking, perhaps in part due to the challenges involved in accurately diagnosing children with ASD at this age and the rapidly changing social and communication profiles of children younger than 3 years (Zwaigenbaum et al., 2009). Wallace and Rogers (2010) reviewed evidence-based practices for intervening with infant populations in other disorders and have highlighted essential components of treatment programs for infants and toddlers that could be applied to intervention programs for infants with ASD. These are (1) parent involvement in intervention, including parent-child interaction therapies that involve coaching parents to alter their own communication and responses to the child in order to maximize language and communication opportunities (cf. Green et al., 2010); (2) individualization to each infant’s developmental profile; (3) focusing on a broad rather than a narrow range of learning targets; and (4) temporal characteristics involving beginning as soon as the risk is detected and providing greater intensity and duration of the intervention. These developments will require clinicians to be alert to the early warning signs of disorder and develop skills in working with and through parents as children are diagnosed at ever earlier ages.

Conditions Associated with ASD

Pragmatic Language Impairment (PLI) or Semantic-Pragmatic Disorder

Rapin and Allen (1983) were the first to describe a communication profile in which children with DLD did not have a primary deficit with language *form*, but substantial impairments in language *content* and *use*; these children were labeled with “semantic pragmatic disorder” (see also Bishop & Rosenbloom, 1987). Bishop (1998) later proposed the term “pragmatic language impairment” (PLI) because semantic and pragmatic deficits did not always co-occur. Children with PLI are those with intermediate symptom profiles that are not severe enough to warrant a diagnosis of autism, but whose language difficulties affect communication, social interaction, and use of language in context. From the beginning, there has been significant clinical and theoretical debate as to whether these children constitute a unique diagnostic entity or whether they have a social-cognitive deficit that is more consistent with a diagnosis of ASD. Part of the difficulty in resolving this debate is that diagnostic criteria for ASDs are constantly evolving, and many would argue are more inclusive than they once were (Bishop, Whitehouse, Watt, & Line, 2008). Interestingly, the new DSM-V criteria would almost certainly preclude a diagnosis of ASD to most children with

PLI, as these children do not generally show evidence of restricted or repetitive patterns of behavior, interests, or activities (Bishop & Norbury, 2002). Nevertheless, children with ASD will have pragmatic language impairments, it is just that other diagnostic groups may also experience pragmatic language difficulties (Martin & McDonald, 2003).

It may be most helpful to think of pragmatic language impairment as a descriptive term rather than a diagnostic category, which can be applied to children with DLD and ASD alike (cf. Rapin & Allen, 1983). Indeed, Norbury et al. (2004) found that children with DLD who were not thought to have significant pragmatic deficits nevertheless achieved lower scores on pragmatic sub-tests of the CCC-2 (Bishop, 2003) than typical peers. However, these low pragmatic scores were entirely in keeping with their low scores on structural language scales; children with PLI profiles who do not have ASD will have problems with conversation, using language context to resolve ambiguity, and difficulties with narrative that are out of keeping with their structural language impairments. Those individuals with ASD who did not have structural language impairment showed disproportionate weaknesses on pragmatic measures. Finally, most children with ASD will have social communication deficits that are far worse than would be predicted given language ability. However, it is important to remember that many children with ASD have additional language difficulties, and that these children also have rigid interests and behaviors that will interfere with pragmatic language development.

Nonverbal Learning Disability

Byron Rourke et al. (Rourke, 1995; Rourke et al., 2002) advanced the idea that there is a distinct clinical syndrome in which children show a profile of skills that is opposite of the one seen in DLD. Children with nonverbal learning disabilities (NLD) have normal verbal IQs, but nonverbal IQs that are significantly below verbal scores. You will probably recognize that this is quite an unusual cognitive profile; of all the disorders we reviewed so far, apart from Williams syndrome, if verbal and nonverbal abilities are discrepant, it is usually verbal abilities that are more impaired. Investigators have reported that children with NLD have particular difficulties with visual-spatial, visual-motor, and fluid reasoning measures compared to children with other developmental disorders (Semrud-Clikeman, Walkowiak, Wilkinson, & Christopher, 2010). Other reported deficits include bilateral tactile-perceptual and coordination deficits, deficits in novel problem solving and concept formation, poor mechanical arithmetic skills in the context of well developed rote verbal capacities, proficient single word reading, and fluent speech. Behavioral descriptions have highlighted deficient social perception and judgment, verbosity, repetitive speech, and problems adapting to novel situations (Rourke & Tsatsanis, 2000).

These descriptions highlight difficulties with pragmatic aspects of language (Volden, 2004) and have invited comparisons with children diagnosed with “high-functioning” autism or Asperger’s syndrome (Klin et al., 1995; Williams et al., 2008). There is an assumption that the pragmatic deficits of both groups stem from deficits in right hemisphere brain functions, but neurobiological evidence for this view in children is lacking. There is considerable controversy about whether NLD is a distinct diagnostic entity, Williams et al. suggest that, for children with obvious social-communication impairments, diagnosis often hinges on the profile of discrepancy seen on a Wechsler IQ test; if VIQ is less than PIQ, children may be more likely to receive an ASD diagnosis, if the opposite pattern is seen, children may receive an NLD diagnosis.

This is clearly not ideal and there are no longitudinal data to assess the stability of this IQ pattern over time. It is also clear that children may well have an NLD profile without having NLD (Williams et al., 2008). When VIQ is greater than PIQ, we need to ensure that children with this profile are properly assessed for pragmatic function, so that they may qualify for SLP services. To this end, measures such as the Children’s Communication Checklist—2 (CCS-2; Bishop, 2003) may be most effective in highlight pragmatic language impairments in children with good structural language skills (Volden & Phillips, 2010).

ADHD

In recent years, the number of children receiving services for ADHD, and the amount of research relating to this disorder has grown exponentially (Bishop, 2010). This is not surprising; ADHD is a debilitating and chronic condition that affects the child’s ability to control attention and behavior in an optimal and adaptive manner (Hulme & Snowling, 2009). Revisions to DSM-V (APA, 2010, see www.dsm5.org) suggest two components to the disorder: inattention and hyperactivity/impulsivity. Children can have predominantly Inattentive or Hyperactive subtypes, or they can have a combined subtype, in which criteria are met in both domains (Box 4-6). The symptoms of ADHD must be present for at least 6 months, with an onset before the age of 12, be present in two or more contexts (i.e., both at home and at school), and significantly interfere with social, academic, or vocational functioning before a diagnosis can be made. According to DSM-IV, the prevalence rate is approximately 3% to 5% of school-aged children with boys outnumbering girls 3:1. When ADHD is primarily of the inattentive type, problems with poor attention and concentration, distractibility, poor organizational skills, and difficulty completing tasks without close supervision occur. Children with the hyperactivity/impulsivity type may be described as fidgety, always on the go, interrupting and talking incessantly, and acting without thinking.

Cognition

The majority of children with ADHD will have nonverbal IQ scores within the normal range, though ADHD has also been observed in children with ID and children with exceptional IQs (above 120; Katusik et al., 2011). Interestingly, Katusik et al. (2011) did not find any differences between children with high, low, and average IQ scores with respect to severity of ADHD symptomatology, rates of stimulant medication, or rates of co-morbid disorder. Children with high IQs were more likely to have highly educated parents, and as a group had significantly higher scores on measures of literacy. It is also important to remember that, across developmental disorders, rates of co-morbidity with ADHD are high and the interactions between ID and ADHD in these populations have not been fully explored.

Despite normal range IQ, there are differences in the cognitive profiles of children with ADHD that may affect language learning and language processing. For a long time, disruptions in the development and deployment of executive functions were thought to be the core cognitive deficit in ADHD (Barkley, 1997). You’ll remember that executive functions (EF) are cognitive processes associated with the frontal lobes of the brain that enable us to remember, plan, organize, and inhibit irrelevant information/responses in order to achieve our goals. However, not all children with ADHD demonstrate impairments on measures of EF (Wilcutt et al., 2005). EF functions that

BOX 4-6 Diagnostic Criteria for ADHD*

1. **Inattention:** Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that directly affects social and academic/occupational activities.
 - a. Often **fails to give close attention to details** or makes careless mistakes in schoolwork, at work, or during other activities
 - b. Often has **difficulty sustaining attention** in tasks or play activities
 - c. Often **does not seem to listen** when spoken to directly
 - d. Frequently **does not follow through** on instructions
 - e. Often has **difficulty organizing tasks** and activities
 - f. Characteristically avoids, seems to dislike, and is **reluctant to engage in tasks that require sustained mental effort**
 - g. Frequently **loses objects** necessary for tasks or activities
 - h. Is often **easily distracted** by extraneous stimuli
 - i. Is often **forgetful** in daily activities, chores, and running errands
2. **Hyperactivity and Impulsivity:** Six (or more) of the following symptoms have persisted for at least 6 months to a degree that is inconsistent with developmental level and that directly affects social and academic/occupational activities.
 - a. Often **fidgets** or taps hands or feet or squirms in seat
 - b. Is often **restless** during activities when others are seated
 - c. Often **runs about** or climbs on furniture and moves excessively in inappropriate situations; in adolescents or adults, may be limited to feeling restless or confined
 - d. Is often **excessively loud** or noisy during play, leisure, or social activities
 - e. Is often **"on the go,"** acting as if "driven by a motor." Is uncomfortable being still for an extended time, as in restaurants, meetings, etc.; seen by others as being restless and difficult to keep up with
 - f. Often **talks excessively**
 - g. Often **blurts out an answer** before a question has been completed; older adolescents or adults may complete people's sentences and "jump the gun" in conversations
 - h. Has **difficulty waiting his or her turn** or waiting in line
 - i. Often **interrupts or intrudes** on others
 - j. Tends to **act without thinking**, such as starting tasks without adequate preparation or avoiding reading or listening to instructions; may speak out without considering consequences or make important decisions on the spur of the moment, such as impulsively buying items, suddenly quitting a job, or breaking up with a friend
 - k. Is often **impatient**, as shown by feeling restless when waiting for others and wanting to move faster than others, wanting people to get to the point, speeding while driving, and cutting into traffic to go faster than others
 - l. Is **uncomfortable doing things slowly and systematically** and often rushes through activities or tasks
 - m. Finds it **difficult to resist temptations or opportunities**, even if it means taking risks

*American Psychiatric Association. (2010). Proposed criteria for ADHD. *Diagnostic and Statistical Manual of Mental Diseases—V*. Washington, DC: Author.

are most likely to be impaired in ADHD include inhibition, working memory, and planning. Cognitive theories of ADHD are being refined and researchers and clinicians are recognizing the role of reward processing and motivation, as well as delay aversion in understanding ADHD behavior. In other words, children with ADHD find it difficult to wait for something desirable, even if the pay off for waiting brings greater reward; if given the choice between \$2 now or \$20 tomorrow, children with ADHD are far more likely than peers to take the money and run (Aase & Sagvolden, 2006)! The ability to defer gratification underlies our ability to sustain attention and work consistently; without this ability it is very difficult to learn to control impulses, and distracting behavior results. These problems may be exacerbated with lower levels of arousal, which may lead to "sluggish" performance and a lack of effort (Sergeant, 2005). In reality, it is likely that the complex behavioral profile that characterizes ADHD can only be explained by multiple cognitive deficits; from our point of view, we need to know how deficits in EF, motivation, and arousal may affect language development, and how these cognitive deficits will influence service delivery.

Language

Although many children with ADHD do not present with any additional language impairments, language profiles are variable and rates of co-morbidity are higher than would be expected in the general population (Im-Bolter & Cohen, 2007), though others have reported that it is only when language impairments and

speech sound disorders occur together that there is an increased rate of co-morbid ADHD (McGrath et al., 2008). The nature of the relationship between DLD and ADHD is a matter of debate. One possibility is that the two disorders may have at least some biological risk factors in common. For example, neural circuits in the frontal lobe of the brain have been implicated in ADHD, and at least partially overlap with neural circuitry involved in language production (Nicolson & Fawcett, 2007). Another possibility is that the cognitive and behavioral deficits associated with ADHD can disrupt language learning and/or language processing. Imagine the toddler who is irritable, disruptive and constantly on the go—opportunities for engaging and interacting with this child in a way that supports language growth may be limited (not to mention the exhausted and frustrated parent may struggle to communicate optimally)! However, poor language skills may lead to behaviors that are reminiscent of ADHD. For instance, if you were asked to sit through a lecture on particle physics, it wouldn't be long before your mind began to wander and you started fidgeting. Regardless of the causal relationship between the two, the clinician needs to be alert to the fact that many, though not all, children referred because of problematic behavior may have additional language impairments. Let's consider what the pattern of impairment is likely to be.

Form

There is no evidence that children with ADHD as a group have disproportionate difficulties with phonology or speech sound production. Redmond et al. (2011) reported that clinical markers of

specific language impairments, such as tense marking, sentence repetition, and narrative, reliably distinguished children with ADHD from those with primary DLDs. However, the ADHD group did not differ from typical peers on overall levels of verbal ability; it is not clear whether those with co-morbid ADHD and language impairment would have distinctive profiles of grammatical impairment, or whether they would be phenotypically similar to children with DLD. Using a similar participant design, Cardy et al. (2010) found that both ADHD and DLD groups had difficulties with rapid temporal processing of auditory stimuli, but that the children with ADHD had greater difficulty on nonverbal tests of processing speed than DLD counterparts.

Content

Studies involving in-depth assessment of the vocabulary and semantic skills of children with ADHD are lacking. In contrast, studies of adults with reported histories of attention difficulties has revealed those with ADHD were less accurate at mapping semantic features and slower to respond to lexical labels than both typical adults and adults with a history of language impairment only (Alt & Gutmann, 2010). These results suggest that it is likely that receptive vocabulary scores will be in the average range, but that children with ADHD may have subtle difficulties rapidly accessing the lexicon, or making connections between words. Such difficulties may be most evident when flexible word knowledge is needed, for example, in understanding humor and non-literal language, making inferences, and understanding metaphor.

Use

The ability to use language in socially appropriate ways is most likely to be a problem for children with ADHD. Using the Children's Communication Checklist (Bishop 1998, 2003), researchers have found that children with ADHD are reported to have significant pragmatic language difficulties, sometimes indistinguishable from peers with ASD (Bishop & Baird, 2000), though unique profiles have also been reported (Geurts et al., 2008). Problems with inappropriate initiation, interruption, difficulty maintaining a topic, and responding with appropriate amounts of information are more likely to be evident in the conversations of children with ADHD relative to comparison groups (Bishop & Baird, 2000; Mikami et al., 2010). Difficulties with pragmatic aspects of language have been found to mediate social skills deficits in this population (Leonard, Milich, & Lorch, 2011).

Literacy

Rates of co-morbidity between ADHD and reading disorders (RD) are extremely high; the prevalence rates for each disorder alone in the general population is approximately 5%, while the rates of co-morbid disorder are 25% to 40% (Wilcutt & Pennington, 2000). Numerous studies have attempted to identify the genetic and cognitive risk factors that are specific to each disorder and those that are potentially shared. Recently, McGrath et al. (2011) reported that processing speed was the only cognitive variable with significant unique relationships to both RD and ADHD dimensions, particularly inattention aspects of ADHD. Notably, naming speed and working memory were not associated with both dimensions. This pattern of findings highlights the multiple cognitive skills that are necessary for skilled fluent reading; limitations in processing speed may result in slow and labored reading of single words in connected text.

As in all other populations, reading comprehension is influenced by both word recognition skills and oral language skills, however aspects of ADHD behavior also seem to predict differences in reading comprehension skills (Cutting et al., 2009). In

particular, deficits in EF can adversely affect how the child approaches the reading task itself, particularly in the child's ability to effectively plan and organize reading tasks (reading headings, linking pictures with text, reading introductions and summary paragraphs, predicting what might happen) as well as monitoring comprehension (realizing when a word or passage doesn't make sense and taking steps to improve comprehension through utilizing surrounding context, use of a dictionary, etc.) (Locasio et al., 2010).

Finally, many studies exploring the relationship between ADHD and RD have focused on the overlapping genetic contributions to disorder, but such studies tell us important things about environmental influences as well (Hart et al., 2010). For instance, the child's disruptive behavior can have implications for the learning environment; sitting quietly with a book is something the child with ADHD may find particularly challenging, reducing opportunities for exposure to text. Remember, too, that level of maternal education has been associated with reading outcomes for children with ADHD (Katusik et al., 2011), suggesting that early and consistent exposure to books and literacy as a pleasurable experience may help to increase motivation to read in these children.

Implications for Clinical Practice

You may have noticed that ADHD diagnosis is on the rise and almost every classroom will include a child with ADHD. Most of these children will be receiving pharmacological interventions; drug treatments of choice include methylphenidate (Ritalin), dextromphetamine (Dexedrine) Adderall, and pemoline (Cylert). There is considerable evidence that drug treatments are successful in reducing the adverse behaviors associated with ADHD, at least in the shorter term (MTA, 2004). Their success over the longer term appears to be influenced by drug compliance; the SLP should therefore be prepared to work closely with the child's family, physician, and school nurse about the medication regime and any changes in prescription or behavior. The effectiveness of behavioral interventions is decidedly more mixed (Young & Amarasinghe, 2010), though most guidelines for best practice advocate treatment protocols that combine medication with behavioral interventions (NICE, 2008). Behavioral treatments will include family therapy and support to deal with challenging behavior and to foster good language and communication experiences, interventions aimed at modifying the environment at home and at school to maximize attention and minimize distraction, and direct behavioral interventions with the child to help him or her internalize rules, develop strategies for planning and organizing work and managing his or her own behavior. Specific strategies for the school-aged child with ADHD are outlined in [Box 4-7](#).

Selective Mutism

The SLP is usually the first professional consulted when a child is not speaking at school. Selective mutism (SM) may be diagnosed in a child who consistently does not speak in certain situations, such as school, where there is an expectation for speech, but does speak normally in other situations, like at home (Steinhausen, Wachter, Laimbock, & Winkler-Metzke, 2006). The text revision of the DSM-IV (DSM-IV-TR) (APA, 2000) further stipulates that SM must persist for more than 1 month (not including the first month of school), and cannot be accounted for by a DLD or by unfamiliarity with the language environment. It is also recommended that bilingual children are not diagnosed with SM unless the mutism persists

BOX 4-7 Classroom Strategies for Children with ADHD**UNIVERSAL LEVEL OF INTERVENTION**

- Model and practice explicit strategies for memorization, test-taking, study, and active reading
- Verbal and written practice focused on reading comprehension instruction
- Monitoring of how to organize notebooks and binders and written work
- Use planners and calendars
- Develop and teach clear school-wide or class-wide expectations
- Teachers use prompts and signals to remind students to follow rules
- Staff practice active supervision, scanning for problem areas or interactions, and interacting frequently with students to reduce problem behaviors

SECONDARY (TARGETED) LEVEL OF INTERVENTION

- Peer tutoring: benefits children with ADHD by providing individual attention, a self-determined pace, and frequent prompting and feedback
- Providing choices: can increase engagement and work completion for children with ADHD
- Note-Taking: teach students to create an outline based on lecture materials, including main idea and supporting details, and to teach the effective use of self-questioning
- Parent Involvement: provide frequent, brief home-school communication focused on progress toward goals and on solving problems before they grow

TERTIARY (INDIVIDUALIZED) LEVEL OF INTERVENTION

- Computer-assisted instruction provides students with ADHD immediate feedback, one-to-one attention, and content presented in an interesting way
- Well-constructed computerized instruction uses color and design to help the student focus on critical information, breaks material down into smaller chunks to promote mastery, provides immediate feedback, and addresses specific instructional objectives
- Functional behavioral assessment to identify behavior(s) of greatest concern and the triggers for those behaviors
- Implement plan to reinforce positive or pro-social behavior and reduce problems
- Encourage self-monitoring by teaching children to observe and record their own behaviors (such as on-task behavior)
- Use a reminder system such as the Motiv-Aider (www.habitchange.com), an electronic pager-type device that sends a silent pulsing signal and does not require verbal teacher reminders
- Provide checklists of important tasks or steps for students to complete tasks

beyond 6 months or is evident in both languages (Toppelberg, Tabors, Coggins, Lum, & Burger, 2005). It is a relatively rare disorder, with prevalence rates of 0.3 to 0.8 per 1000 (DSM-IV-TR, APA, 2000) and, unlike other DLDs, it is much more common in girls, with a gender ratio of 2:1 (McInnes et al., 2004).

SM is generally regarded as an anxiety disorder, rather than a variant of DLD (Steinhausen et al., 2006; Vecchio & Kearney, 2005). However, social anxiety is rarely the only problem and language impairments are frequently present in children with SM; 60% to 75% of children with SM have some form of language impairment (Sharkey & McNicolas, 2010). This strongly suggests that self-consciousness about communicative abilities plays a part in maintaining the disorder. Assessment of language in a child with SM is likely to be challenging, as most children are reticent to speak when they feel they are under the spotlight. Initial investigations may therefore centre on taking a detailed case history from the parents detailing where, when, and with whom the child does speak and obtaining examples of the child's communicative efforts in different contexts for transcription of spontaneous speech (McInnes et al., 2004). Unobtrusive observation of the child playing alone, or with parents and siblings, may also give an indication of the child's language abilities.

The most successful treatments are reportedly those that combine behavioral and pharmacological interventions, though there is limited research on the efficacy of this approach (Cline & Baldwin, 2004; Sharkey & McNicolas, 2010). Behavioral interventions should always be considered with input from a multidisciplinary team (psychologist, psychiatrist, SLP, teacher) in close collaboration with families. Strategies may include language therapy, positive reinforcement for speaking, desensitisation to

anxiety-provoking situations, family therapy, and self-modeling techniques, in which the child listens to him or herself speaking in situations in which he or she is usually mute (these and other therapeutic techniques are outlined in Johnson & Wittgens, 2001). McInnes and Manassis (2005) suggested that intervention should take into account the child's social anxiety and begin by encouraging the child to articulate rote language (numbers, days of the week) or answer simple, factual questions (what color is this?) rather than asking questions that involve self-disclosure (what is your favourite color?). In addition, public speaking should progress in stages, at first involving a parent or one person the child does talk to and increasing confidence with speaking to a familiar person (teacher), then group of familiar people (class-mates) before tackling unfamiliar people (restaurant or shop). Techniques that have been used with this population are summarized in Box 4-8. Longitudinal studies report improvements in the core symptoms of SM over time, though rates of psychiatric disorder, especially social phobia, remain high and prognosis is particularly poor when there is a family history of SM (Steinhausen et al., 2006).

DLD ASSOCIATED WITH EXTREME ENVIRONMENTAL DISADVANTAGE

DLDs that result from maternal substance abuse, such as alcohol, or from parental maltreatment, such as abuse and neglect, are some of the most tragic aspects of our clinical practice because these kinds of disorders could have been prevented. As Joseph's story indicates, these factors often operate in concert to produce a range

BOX 4-8 Strategies for Intervening with Selective Mutism

1. Stimulus fading: audience or setting changes, rather than the child
 - a. Child talks alone with trusted adult (parent) and anxiety is introduced; e.g., clinician stands outside leaving the door ajar so that the child may be heard. Child is encouraged to keep talking.
 - i. Gradually increase proximity to child
 - ii. Avoid direct eye gaze
 - iii. For older children, make a specific, non-threatening speech target such as counting, or days of the week, until comfortable with other person present
2. Shaping: child's behavior starts to change
 - a. Start with nonverbal communication with clinician (or key-worker) in minimal anxiety situation
 - b. Gradually increase child participation
 - i. Increase eye contact
 - ii. Increase voicing and volume
 - iii. Increase number/length of words and messages
 - c. Create communication games to elicit speech from child, for example, barrier games or Simon says
 - d. Positively reinforce all verbal communication
3. Desensitization: child gets used to thought of doing something that he or she would not previously have considered
 - a. Child allows others to hear recording of voice
 - b. Child speaks to friends/family on telephone, before face-to-face meeting
 - c. Child speaks to class teacher in person in whispered voice
 - d. Ensure child is aware of targets and can monitor successes
 - i. Use motivators such as stickers
 - e. When progressing, change only one thing at a time; if child is comfortable speaking with a friend at home, try speaking with teacher at home OR speaking to friend in class, but not speaking to teacher in class

of long-term developmental problems. In this section, we will outline the communication patterns seen in children exposed to these hazards to understand how they might influence clinical decision making. We'll talk about two major types of environmental disadvantage: maternal substance abuse and maltreatment.

Joseph was born to a mother who had been severely alcoholic during her pregnancy. During his stay in the hospital it was noted that he had some dysmorphic facial features, including microcephaly (small head size), micrognathia (small jaw), a thin upper lip with an indistinct philtrum, and a flat midface. He was extremely irritable as an infant. During his preschool years, Joseph's mother continued to drink and she also began using cocaine. She was often absent, leaving Joseph with whatever neighbor would take him, while she earned money by prostitution to buy drugs. Joseph grew slowly in size. He experienced many developmental delays, including late motor milestones, slow language development, and eventually poor reading and spelling. When his mother enrolled herself in a drug treatment program when he was 3, he was assessed and diagnosed with Fetal Alcohol Syndrome (FAS). His IQ was in the low average-borderline range and he was enrolled in an intervention program while his mother completed the drug rehabilitation program. Both made significant progress and, by age 5, Joseph was enrolled in a mainstream classroom. He was very personable and chatty, but still required special educational support. He had difficulty understanding classroom instructions and struggled with reading lessons and arithmetic. In high school, his poor judgement and impulsive behavior often got him in trouble. At 16, he dropped out.

Recent research using brain imaging techniques reveals that environmental disadvantage can have a profound effect on structural and functional brain development, especially in the domains of language and prefrontal executive control (Tomalski & Johnson, 2010). It is important to remember that it is not necessarily the substance itself or the lack of parental warmth and contact that can lead to these changes, but the environmental circumstances that are not conducive to child development. Other factors include poor diet, increased exposure to accidents and other risks, and a lack of stimulating opportunities and experiences. Individuals from deprived backgrounds are also less likely to seek help from professional services, or to comply with clinical or educational recommendations, making this a particularly challenging client group.

Abuse/Neglect

The World Health Organization (WHO) estimates that 40 million children below the age of 15 experience abuse and neglect requiring health and social care. Types of maltreatment may include physical abuse, sexual abuse, emotional abuse (excessive belittling, verbal attack, or overt verbal rejection), and neglect (abandonment, inadequate supervision, failure to provide necessary items such as adequate nutrition or clothing). Children experiencing abuse and neglect are likely to be on clinical case-loads because children with developmental disorders and language impairments are more likely to be abused than typically developing children (Sullivan & Knutson, 2000), and because, as we have seen, abuse and neglect may disrupt development, especially for language and executive control processes (Tomalski & Johnson, 2010).

Specifically, maltreatment interferes with normal social-interaction processes and thus reduces the opportunities for language learning in socially meaningful exchanges. As a result young maltreated children may have reduced rates of vocabulary growth and shorter

MLUs than nonabused peers (Coster, Gersten, Beeghly, & Cicchetti, 1989). Deficits in expressive syntax persist into school age (Eigisti & Cicchetti, 2004) and adolescence (McFayden & Kitson, 1996), though vocabulary scores may improve to near normal levels in the oldest groups. Less has been reported about the social communication skills of children experiencing maltreatment, but such children are reported to have difficulties using language to articulate their feelings and needs as necessary for self-regulation; to convey abstraction, which is necessary for advanced literacy and reading comprehension; and to sustain coherent narrative dialogue, which is key to social exchange (Coster & Cicchetti, 1993). In addition, maltreated children are more likely than peers to engage in challenging behaviors that are likely to elicit further negative reactions from teachers and peers (Westby, 2007).

Fetal Alcohol Spectrum Disorder (FASD)

Maternal substance abuse can affect a child's development in at least two ways:

1. Substances such as alcohol and cocaine can have negative effects during prenatal development. These substances can cross the placental barrier and affect the intrauterine environment. In the case of alcohol, the fetus is unable to metabolize the alcohol as an adult can. Alcohol acts as a teratogenic agent and interferes with chemical processes in fetal cells. Abuse of other drugs, such as cocaine, can increase the probability of a premature birth, which carries its own set of developmental risks.
2. Language and communication development is also influenced by the effects of substance abuse on the caregiving environment. A mother (or father) who is frequently drunk, high on drugs or driven to get drugs by any means necessary is not a person who can devote much energy to childrearing. These parents often have difficulty understanding their children's communication attempts and may not respond appropriately to them, often rejecting or criticizing their efforts (Sparks, 2001).

In fact, Coggins, Timler, & Olswang (2007) refer to this as a "double jeopardy," pointing out that it is often challenging to separate the effects of the substance itself from the chaotic environments that are prevalent in maternal substance abuse. Understanding cognitive and language outcomes in these children requires exploration of both.

FASD is a syndrome of birth anomalies associated with excessive alcohol intake during pregnancy. Originally referred to as Fetal Alcohol Syndrome, the change in diagnostic label reflects the differing degrees of impairment and outcome associated with the disorder. Different diagnostic criteria are employed in different countries, but all include the following four criteria (Institute of Medicine, 1996):

1. Confirmed or unconfirmed maternal alcohol exposure.
2. Facial features—evidence of a characteristic pattern of facial anomalies that includes short palpebral fissures and anomalies in the premaxillary zone (e.g., flat upper lip, flattened philtrum, and flat midface).
3. Growth retardation—at least one of the following:
 - Low birth weight for gestational age
 - Decelerating weight over time not due to nutrition
 - Disproportional low weight to height

4. Central nervous system (CNS) abnormalities—at least one of the following:

- Decreased cranial size at birth
- Structural brain anomalies
- Neurological hard or soft signs (age appropriate)

FASD is a lifelong disorder, and there is a predictable progression of maladaptive behaviors and communication disorders, outlined in Box 4-9. DLDs are universal in this population and may be related to overall cognitive achievements (Cone-Wesson, 2005). In reviewing a large body of research in this area, Kodituwakku (2009) concluded that children with FASD have a generalized deficit in the processing and integration of information, with resulting deficits in nonverbal IQ scores and measures of language processing, relative to their peers. Others have emphasized

BOX 4-9 Characteristics of Fetal Alcohol Spectrum Disorder

INFANCY AND EARLY CHILDHOOD

- Sleep disturbances
- Poor sucking response
- Failure to thrive
- Prone to middle ear disease
- Poor habituation
- Delays in walking and talking
- Delays in toilet training
- Difficulty following directions
- Temper tantrums

SCHOOL YEARS

- Hyperactivity, distractibility
- Poor attention
- Delayed motor, cognitive, and speech development
- Difficulties understanding consequences of actions
- Temper tantrums and conduct problems
- Fine motor difficulties
- Learning and memory problems
- Lack of inhibition
- Interest in social engagement, but poor social skills
- Indiscriminate attachment to adults
- Withdrawal, depression
- Poor judgement, difficulty matching aspirations to ability, failure to learn from past experience
- Good verbal facility, giving appearance of strong verbal skills, but poor language comprehension
- Better performance in reading and writing than in mathematics
- Good performance on concrete tasks, poor abstract reasoning

ADOLESCENCE

- Reach academic ceiling
- Depression, social isolation
- Naive, childlike manner
- Sexual difficulties (inappropriate behavior, easily exploited)
- Poor impulse control
- Difficulty seeing cause-effect relationships
- Memory, learning, attention, activity, and judgment problems persist
- Pragmatic language difficulties
- Truancy and school dropout problems

deficits in social communication, particularly difficulties in producing narratives that have sufficient semantic elaboration and referencing (Coggins et al., 2007; Thorn & Coggins, 2008). Deficits in executive control are also likely to impact on pragmatic language skills.

Clinical Implications

Speech-language clinicians have a number of responsibilities and challenges when working with children experiencing extreme environmental disadvantage. First and foremost, clinicians have a legal duty to report maltreatment and prevent the child coming to harm. This can be tricky in culturally diverse communities where standards of discipline and parent-child interaction may differ from our own. Westby (2007) addresses these issues and stresses that any practice that causes a real and present danger to the child requires immediate action.

A second consideration is that the physical characteristics associated with FASD and the environments children are exposed to increase the risk of middle ear disease (Cone-Wesson, 2005). Thus, careful monitoring of hearing status is advocated. Maltreated children and children with FASD are also very likely to have challenging behaviors and may meet criteria for ADHD. Working as part of a multidisciplinary team will be necessary to reduce undesirable behaviors and encourage language for the purposes of reflection, negotiation, and behavioral control.

Numerous treatment approaches have been proposed; these cover skills such as executive function, language processing, and social communication skills (Jirikowic, Gelo, & Astley, 2010; Paley & O'Connor, 2009; Peardon et al., 2009). The most methodologically robust studies show treatment gains in language, literacy, and social skills. Intervention studies differ considerably in quality, in treatment content, context, and in dosage (i.e., amount of treatment offered). All of these factors are likely to influence outcome and clinicians should take these factors into account when planning intervention services.

THE NONSPEAKING CHILD

Some of the children SLPs treat have limited, if any, spoken language. For these clients, we have two immediate assessment priorities; first, to establish the child's level of comprehension and second, to establish whether any intentional communication is taking place, and if so how and for what purposes. Knowing how much a child understands will help both to structure our own input and to select among language goals in production. Criterion-referenced assessment methods may be useful here. In Chapters 6 and 7, we'll discuss in detail some assessment techniques that can be used to establish nonverbal, intentional communication. Knowing that a child has a desire to communicate can help us distinguish between language problems that arise from impairments to oral-motor structures and functions or sensory impairments from those that are associated with psychiatric conditions such as selective mutism or autism spectrum disorders. Here, knowing what is causing the problem is very important because we will need to tailor our interventions to the particular needs of the child. For many nonspeaking children AAC should be considered, even if only as a temporary bridge to other communication systems, in order to provide the child with a viable communication system of some kind. Let's take a look at some of the issues that arise when assessing and recommending AAC for the nonspeaking child.

Severe Speech-Motor Disorders

Many disorders can affect the orofacial structures or neuromotor functions that serve speech production. Some of these can leave the understanding and formulation of language, as well as general cognitive skill, more or less intact, resulting in more circumscribed speech impairments. Cerebral palsy, certain congenital facial anomalies, and brain injuries specifically affecting neuromotor tracts are some examples. In Chapter 3 we discussed some principles to use in making decisions about augmentative communication for children with severe speech and physical impairment (SSPI). We'll want to apply those principles when choosing an augmentative or alternative system for these clients. Many such disorders also affect feeding and swallowing. These problems require an intervention program beyond the scope of this text, but clinicians should be aware of the need for assessing and planning treatment (perhaps in collaboration with physical and occupational therapists) for these aspects of the disability in children with SSPI.

Sturm and Clendon (2004) discussed some of the reasons why children with SSPI may have trouble learning language. Some have to do with the external barriers they face. They cannot learn through the usual sensorimotor interactions with people and objects because of their physical disabilities. They don't have constant access to their mode of communication as speakers do; if they use a board or device, someone has to get it and set it up for them before they can communicate. Their limited mobility gives them fewer opportunities to interact with other people. They aren't able to develop from babble to speech by playing with sound and using sound as interaction tool; devices and outputs are chosen for them and may not be the best match for their abilities and intentions. In designing language-learning systems for individuals who use AAC systems, we will need to modify our usual approach. Instead of focusing on the next developmental stage of language output, we need to focus more on the child's comprehension skills (Wilkinson & Henning, 2007). Miller and Paul (1995) provided a variety of techniques for comprehension assessment that can be used with this population. It is also important to assess pragmatic and cognitive skills in this population, since these assessments give some idea of the concepts and social interactions the client is using spontaneously. We can then follow the child's developmental profile by targeting words and word combinations that would be expected given the child's cognitive, comprehension, and communicative profile.

One research finding of particular relevance is that a communication device that provides voice output, in other words it "speaks" what the child selects to communicate, is very effective in stimulating speech and language growth (Millar et al., 2006). These voice output communication aids (VOCAs) should, whenever possible, be part of the AAC system for our clients with SSPI. Light et al. (2004) and Rispoli et al. (2010) have reviewed the advantages and disadvantages of various aids and the evidence for their treatment efficacy. Emerging technologies are making these systems much more accessible and less expensive. As just one example, Proloquo2go is a speech generating system that can be used on an iPhone, iPod, or iPad. These devices are much more inclusive and less stigmatizing than traditional AAC devices.

Wilkinson and Henning (2007) discussed a number of different communication roles that the SLP should consider in relation to AAC. First, although AAC devices are often aimed at increasing language output, Wilkinson and Henning remind us that, for some children, these devices will also open doors to language

understanding as well as nonverbal communicative exchanges. Second, they highlight the importance of ensuring that the vocabulary targeted can be used for a range of communicative functions; users of AAC must be able to do more than request, protest, and answer questions, they must also comment, ask questions, express emotions, and build relationships. A third role of AAC is to reduce challenging behaviors by providing an alternative means of rejecting unwanted approaches and requesting help. Finally, AAC can provide a bridge into symbolic reasoning and later language development.

When introducing vocabulary, it will be important to offer not just single nouns, but “chunks” of language that the child can use as speech acts (e.g., “don’t do that,” “lemme see”). This diversity allows AAC users to choose from the range of language-learning styles seen in normal development. When introducing word combinations and sentences, it may be more important to stress the communicative functions of these utterances, rather than focusing strictly on the grammatical forms needed to express ideas. Still, since speech synthesis devices can be programmed with whole sentences, children using these devices might be given ways to produce sentences such as “I drank all my milk.” These sentences might be possible through the device before the point at which irregular past forms would normally be acquired in developmental sequence. Paul (1997b) has suggested that programming the device with some “giant phrases” (e.g., see you later alligator), often used as gestalt forms by young children, can help the child using AAC to develop the analytical skills these forms facilitate in typical speakers. Wilkinson and Henning (2007) also point out that a combination of preprogrammed phrases alongside single words can also speed up message formulation and reduce cognitive demands for the speaker.

Gerber and Kraat (1992) suggested including talk about “then and there” in the intervention program. The focus on an AAC device may bias the intervention toward talk about the “here and now” for a longer period than would be typical in normal development. Interactive book reading may be a particularly naturalistic context in which such talk could take place (Kent-Walsh et al., 2010). It will be important for clinicians to begin to introduce some talk about past time, predictions about future events, discussions of pretend, and so on. Following some of the guidelines given in Chapter 9 for incorporating play contexts in language intervention can be helpful in achieving this goal. Finally, Wilkinson and Henning (2007) highlight the important role that communication partners may play in modelling the use of the AAC device, in much the same way that adults model language for typically developing children. This will require significant others to use the device themselves, which has the added benefits of enabling communication partners to become familiar with the words and messages available to the child, and reduces the stigma of using the device. As children typically learn language partially through the desire to emulate others, it is important that both adults and peers use AAC as a means of interacting with the child. Children using consumer electronic devices like iPads, rather than more unfamiliar dedicated devices, will find peer partners willing to communicate through the device with them, because of its “cool” factor.

Although for many years children with SSPI were given little access to literacy, much has changed in the last 25 years. Considerable research and clinical effort has been devoted to developing literacy skills and to providing a variety of AAC devices with which to transmit their written messages. This change has literally revolutionized the communicative capacity of many children with

AAC systems increase communicative opportunities for children with severe speech production impairments.

SSPI. Written output, which is understandable by most adults and older children in our culture, allows the child with SSPI to express the full range of meanings available in language to the broadest possible audience. Some children with SSPI will continue to perform below developmental expectations on literacy measures despite instruction, but there are methods that can be used to improve access to the written word. Improving basic language development is an important part of this picture, as is the provision of early, intensive exposure to story-book reading (Wood & Hood, 2004), opportunities for carefully scaffolded phonemic awareness, and letter-sound association. Light and colleagues (Light et al., 2008; Light & McNaughton, 2009) have developed an evidence-based literacy intervention program for users of AAC. Some of their recommended techniques for are outlined in Table 4-3 (see also <http://aacliteracy.psu.edu/>).

Childhood Apraxia of Speech

According to ASHA (2007), childhood apraxia of speech (CAS) is “a neurological childhood speech sound disorder in which the precision and consistency of movement underlying speech are impaired in the absence of neuromuscular deficits....The core impairment in planning and/or programming spatiotemporal parameters of movement sequences results in errors in speech sound production and prosody” (p. 1).

Unlike SSPI, the difficulty here is not the result of muscle weakness, paralysis, or obvious neurological impairment. Instead, in CAS there is a problem with motor planning; the child knows

TABLE 4-3 Strategies for Developing Literacy Skills in Children Using AAC

Literacy Skill	Example Target	Example Activity	Example Materials
Sound blending	Child will listen to sounds and blend them together Child will say word out loud, sign it, or select the correct picture or AAC symbol from a group of 4, with 80% accuracy	Clinician produces sounds in isolation, slowly: "mmmooommm" Child indicates target	Selection of four symbols including: Mom Mop Pot Man
Phoneme segmentation	Child will listen to a phoneme presented orally Child will indicate a word that begins with that phoneme by saying it out loud, signing it, or selecting the appropriate picture or AAC symbol from a choice of four with at least 80% accuracy.	Clinician says "m" Child indicates target word beginning with that phoneme	Selection of four symbols including: Mom Up Bat Pot
Letter-sound correspondences	Child will listen to a target sound presented orally Child will select the appropriate letter from a group of letter cards, an alphabet board, or a keyboard with at least 80% accuracy	Clinician says "m" Child indicates target letter representing that phoneme	Computer keyboard with various letters highlighted (depending on number of letter-sound correspondences child knows)
Decoding	When presented with a simple 3-letter word in print, the child will indicate the word by saying it out loud, signing it, or selecting the appropriate picture or AAC symbol with at least 80% accuracy	Child is presented with written word "big" Child must select the matching picture/symbol from choice of four	Selection of four symbols including: Big Pig Bug Bib
Shared book reading	When the instructor reads a sentence in a book out loud, pauses, and points to a regular 3-letter word in print, the child will indicate the word by saying it out loud, signing it, or selecting the appropriate picture or AAC symbol with at least 80% accuracy.	While reading a short book, clinician points to word so child can see Child points to picture/symbol from display of symbols relevant to the story	Commercially available books or personalized books Symbols representing key characters, events, emotions in the story
Sight word recognition	When a word is spoken aloud, the child will select the matching printed word from a choice of four with 80% accuracy	Clinician says word "big" Child points to matching printed word	Four printed words: Big Bib Bug Pig
Reading simple sentences and stories	When presented with simple written sentence, child will (a) read the sentence, sign the sentence, or match picture to sentence and (b) answer "who is it about?" "what happened" questions with 80% accuracy	Child reads sentence: "the boy has a dog" Child selects picture corresponding to "who is it about?"	Four pictures: Boy with dog Girl with dog Boy with cat Girl with bird Can tailor story/pictures to child's interest
Reading comprehension	Targets may include: Summarizing Generating questions Answering questions Semantic/graphic organizers Predict next words/sentences in text Activate prior knowledge	The clinician models or demonstrates the strategy The clinician provides scaffolding support The clinician gradually fades this support The child has repeated opportunities for independent practice The clinician, child, and family make a plan to ensure generalization and continued use of the strategy	Choose books of interest or curriculum related materials Adapt response options to child's skills and abilities These may include communication boards, symbol book, signing, computer keyboard, computer, or other consumer electronic device with speech output

what he or she wants to say, but there is a deficit in the motor planning/coordination of the articulators necessary to say it. Alternative terms for this problem include *developmental verbal apraxia* or *dyspraxia*.

Assessment of volitional movement patterns for the purpose of performing an action (i.e., puckering lips for a kiss, blowing a bubble) has traditionally been a common clinical approach to identifying CAS. However, Shriberg et al. (2003a, b) compared children with suspected CAS to children with speech sound disorders to find out whether the two groups could be differentiated on the basis of behaviors directly related to speech praxis. They concluded that only two linguistic behaviors differentiated the groups: *inconsistent production of stress* in tasks involving the naming of two-syllable words, and the degree of *variation in the timing* of speech. These results led Shriberg et al. to develop automated speech recognition methods for distinguishing speech samples of children with and without CAS (Hosom, Shriberg, & Green, 2004), leading to more accurate diagnoses. Without these automated, instrumental techniques, however, it can be very difficult for a clinician to be definitive about whether a child is experiencing CAS or developmental speech sound disorder.

For these reasons, there are numerous controversies surrounding CAS. Like “developmental dysphasia” CAS was originally defined as an analogue to an adult acquired neurological disorder, apraxia of speech, or a neurologically based difficulty in programming speech movements, thought to take place at a prearticulatory motor planning level. Intensive investigation, however, has not been able to document any consistent neuropathology in children who show this speech pattern, even using the neuroimaging techniques we outlined in Chapter 1. The fact that the behavioral symptomatology identified with CAS overlaps so much with other conditions, such as speech sound disorder and expressive language

delays, contributes to this view and makes differential diagnosis problematic. Shriberg et al. (2011) reported that the population prevalence of CAS is estimated at 0.1%, and that false positive diagnostic rates run at 80% to 90%. In other words, CAS is a rare disorder and children with other kinds of speech problems are very often misdiagnosed as having CAS. One important fact to note is that CAS affects not only speech sounds, but prosody, particularly stress and timing, as well. And since prosody occurs only in connected speech, it does not make sense to make a diagnosis of CAS unless there is enough continuous speech to judge whether prosody is affected. For this reason, our approach is to counsel caution in diagnosing this disorder. For pre-verbal children, it is simply too early to know whether speech has failed to emerge because of CAS, some other motor speech problem, or a more pervasive communication deficit. In these cases, work on developing receptive language, encouraging vocal production and working toward a first productive lexicon (see Chapter 7) is appropriate, regardless of what the diagnosis turns out to be. A diagnosis should be deferred until there is enough connected speech to judge accurately whether criteria for CAS are met. For children who use connected speech but have poor intelligibility, inconsistent speech errors, and prosodic deficits, CAS can be considered as a diagnosis, but only after other conditions, such as hearing impairment, dysarthria, and more common speech delays have been ruled out; and it is important to remember how rare CAS is. For those few children who do meet criteria for CAS, intervention should focus on developing motor patterns that automatize speech production, primarily through repeated practice of words and phrases, rather than isolated sounds. Sample activities for addressing CAS are presented in Box 4-10. Williams and Stephens (2010) provide an alternative program. Still, it is important to remember that at present there is a woeful

BOX 4-10 Intervention Approaches for Children with CAS

MOTOR APPROACHES

- Massed practice: schedule frequent, short sessions; use a small set of stimuli (5 to 7 words or phrases) practiced over and over before moving on to another small set.
- Use block practice schedules early on: practice each utterance or stimulus many times in a row in the early stages of learning, as these facilitate retention.
- Use random practice schedules later: when production is stabilized, use random practice, in which items are interspersed in random order, to facilitate generalization.
- Provide feedback: provide feedback after a small number, but not every, response. Provide the feedback quickly, within less than a second of the production. Fade the amount of feedback as the intervention proceeds, and encourage client self-monitoring.
- Provide slowed-down models: provide extra time for the client to process and program the target movement. As accuracy of movement increases, increase rate of presentation of stimuli gradually.
- Practice, practice, practice: the fundamental tenet of a motor approach is that learning takes place as a result of repeated successful trials that lead to habituation and automatization of processing. Develop strategies for imitation and practice that go beyond basic sit-and-drill to maintain interest and motivation.

PROSODIC APPROACHES

- Practice analyzing words into syllables: have clients clap out the syllables in a word, or have them use large blocks to represent stressed syllables in a word and small blocks to represent unstressed syllables. Be careful not to produce unnatural stress in word productions.
- Identify stressed syllables in words (which part of rhinoceros is the loudest?) and imitate multisyllabic words with appropriate stress. If necessary, use backward chaining to achieve this (e.g., have the child say y, city, tricity, lectricity, electricity).
- Match phrases with meaning according to stress patterns: have clients match BLACK-board to a picture of a chalk-board, and BLACK BOARD to a picture of a painted board, for example.
- Have children identify stressed words in sentences: initially use exaggerated stress, then gradually fade the exaggeration.
- Use “wh-” questions: have children use stress to contrast between answers to “wh-” questions such as: who ate the cheese? The MOUSE ate the cheese. What did the mouse eat? The mouse ate the CHEESE. What did the mouse do? The mouse ATE the cheese.

Aided AAC devices are sometimes used with children with severe CAS.

lack of research evidence for treatment efficacy for this condition (Morgan & Vogel, 2008).

For children with severe CAS, it may be necessary to supplement speech and vocalizations with AAC in order to facilitate communication for some period of time. But it will also be crucial for these children to receive appropriate, focused, intensive speech-language

therapy, following guidelines like those in Box 4-11. Research suggests that speech disorders tend to improve in these children as they reach school age, while language and literacy problems may persist (Lewis et al., 2004). The danger of CAS as a diagnostic category lies in the tendency to lead clinicians to ignore the language needs of these children to focus on speech production or AAC exclusively. Thus, the clinician needs to ensure that adequate assessment of language content and use, as well as literacy is made, even if speech is the most obvious presenting complaint.

The Nonverbal Child with ASD

As we saw earlier, a small but significant proportion of children with ASD fail to acquire any verbal language. It is also the case that in the early school years many children with ASD may have limited expressive language, though this may improve with time and intensive intervention. What causes some children with ASD to be nonverbal is still a matter of debate, but it is likely that reduced motivation to communicate with others contributes to this problem. Our primary goals, therefore, will be to establish intentional and functional communication for a variety of purposes.

As with other disorders, a likely finding for this population will be that some requests and protests are expressed, but joint attention or social interactions are not. When this is the case, we'll want to do two things. First, we'll want to provide some conventional means—gestures, signs, vocalizations, words, or some form of augmentative communication such as a picture board—for expressing the intents the child is already producing. Second, we'll want to provide extensive support for eliciting joint attentional and social interactive behaviors. When these emerge in presymbolic form, we will need to find more conventional means of expression

BOX 4-11 Intervention Approaches for the Child with ASD Who Is Nonverbal

- Establish receptive joint attention.** Use loud, exaggerated cues and intense reinforcement to encourage child to look at what the clinician points out or looks at.
- Establish initiation of joint attention.** Follow the child's lead AS IF the child were attempting to establish shared attention. Look at or touch object child is engaged with. Intrude so child's attention shifts toward adult, then provide exaggerated praise for looking at and sharing with the adult.
- Work with parents to increase synchronous responses to child's behavior/communication attempts.** Use video to help parents identify child's communicative signals and encourage immediate response.
- Focus on language input.** Help parents to adapt their language and communication to the child's developmental level. Encourage parents to talk about the child's current focus of interest.
- Encourage imitation.** Play "copy-cat" games in which reinforcement is provided for vocal or gestural imitation. Start by imitating the child; then reward the child's imitation of the adult.
- Encourage development of social interactive routines.** Use enjoyable routines (e.g., tickling routines, favourite songs, etc.) and require the child to say or do something and look at the adult before continuing with the game.
- Use sounds the child is already producing to encourage first words.** At first, associate the sound the child makes with a meaningful object or outcome. For instance, link "ooh" sound with a train, saying "choo-choo, yes it's a choo-choo." Reinforce and encourage approximations of adult input.
- Replace unconventional communication.** Replace maladaptive behaviors with gestures, vocalizations, or actions. Try to establish communicative function of challenging behaviors.
- Expand range of communicative functions.** Use communication "temptations" to provide opportunities for child initiation in socially meaningful contexts.
- Develop strategies to maintain and repair breakdowns.** Use highly motivating activities to keep the client focused. Create opportunities for repair by delaying responses or feigning misunderstanding.
- Provide environmental supports to enhance social communication.** Use visually cued instruction (PECS, visual schedules and calendars, sign) and modified linguistic input (exaggerated intonation and facial expression, simple, routine, and repetitive language).

for them. Use of AAC maybe helpful, and may lead to small increases spontaneous speech production (Schlosser & Wendt, 2008). Some techniques for working with the child with ASD who is not producing speech are outlined in [Box 4-11](#).

AAC in ASD

The issue of alternative modes of communication is often raised for nonverbal children with ASD. Although these children have no known motoric impediments to speech, advocates of AAC, using a “communication needs” model, recommend providing AAC to any nonspeaking child, regardless of the reason, because everyone needs some way to communicate (Beukeleman & Mirenda, 2005). Signed language is one alternative often used, though evidence for its functional use in children with ASD is limited (Prelock et al., 2011). In current practice, AAC systems for people with ASD often begin with object or picture exchange systems (Bondy & Frost, 1998). Here the child is given an object (such as a spoon to represent a bowl of cereal to eat) or picture that represents the desired goal, and is taught to give it to the clinician (or parent or education personnel) to obtain the goal. One popular example of this approach is the picture exchange communication system (PECS; Bondy & Frost, 1998). Numerous studies have demonstrated positive effects in language and communication development for PECS users, though direct comparison with other AAC methods, or more direct speech elicitation has not been implemented. Importantly, the child’s developmental level may predict the degree to which a child with ASD adapts to the PECS system; those with developmental levels of 16 months or greater are likely to benefit the most from PECS (Pasco & Tohill, 2011). Other forms of AAC, such as VOCAs, have been studied and appear to be helpful, but studies are few and small. Overall, we can say that AAC methods have been shown to be compatible with the development of speech, although benefit beyond that offered by direct speech-language therapy has yet to be established. Since we know that acquisition of meaningful speech by school entry is a powerful predictor of later outcome (Howlin, 2005), it is important to make every effort to elicit speech during the preschool period. Direct speech instruction, or methods focused on verbal imitation and speech production (cf. Koegel et al., 2006) can be combined with AAC as well as other therapy approaches designed to increase joint attention and social interaction behaviors. However, we know very little about the relative efficiency of these approaches and more research is needed to guide clinicians as to what mix of approaches will yield the most direct route to spoken language. For individuals with ASD, it would seem important to include direct attempts to elicit and develop spoken language so that they may have more opportunity to reach their potential (Helt et al., 2008)

CONCLUSION

This chapter has included a very long discussion of a range of developmental disorders that frequently involve impairments to speech, language, communication, and literacy. Is it necessary to know the ins and outs of all these disorders in order to assess and treat them? Yes and no. Yes, it is helpful to know about these disorders and their key features disorder because these will give us hints about assessment and treatment. We also need information about these disorders so that we can interpret the medical records in case histories, and to facilitate professional dialogues with our colleagues who will form the multidisciplinary teams providing care for these children and their families. Knowing more about

the disorder will also help us to prepare for associated difficulties in behavior, perception, or cognition that may adversely affect language development and that will need to be taken into account when planning treatment and educational programs. However, we could answer “No,” in the sense that knowing all of these things will not help us to know about an individual child’s profile of communication strengths and weaknesses. Thus every assessment will need to start with the child and his or her family, and we must ensure that we do not miss anything important that may not fit our stereotypical profile of a child with a given disorder. “No” is also apt in the sense that there is a great deal of overlap in the cognitive and language characteristics associated with different diagnostic groups ([Table 4-4](#)), and that these categories are not mutually exclusive; as we’ve seen co-morbidity is the norm, not the exception, in developmental disorders. Many of the treatment approaches we use will be applicable across different diagnostic categories. So, knowing a child’s diagnosis is only a signpost; we need to work closely with families to discover their primary concerns and priorities, and to conduct a thorough assessment of a broad range of language and related functions, using the guidelines presented in Chapter 2. Then we need to develop intervention goals and methods based on the assessment data, choosing among a repertoire of procedures and contexts that we discussed in Chapter 3. That’s the real work of designing a language program. While it is influenced by the child’s diagnosis, it cannot be fully determined by it.

STUDY GUIDE

- I. Intellectual Disability
 - A. Define Intellectual Disability (ID) and describe the diagnostic criteria discussed by the American Association of Intellectual and Developmental Disabilities.
 - B. Describe the cognitive and linguistic characteristics of children with ID.
 - C. What are “adaptive behaviors” and why are they important to assess when working with individuals with ID?
- II. DLD associated with Disorders of Known Genetic Origin
 - A. Down syndrome
 1. What causes Down syndrome (DS)?
 2. Describe language form, content, and use in DS.
 3. What are the cognitive characteristics of children with DS and how do they influence language development?
 - B. Williams syndrome
 1. Describe the social skills of children with Williams syndrome (WS).
 2. How are language and cognition related in WS?
 3. What aspects of language content are particularly challenging for children with WS? Why?
 - C. Fragile X
 1. How significant are gender differences in the language and cognitive profiles of children with Fragile X?
 2. High rates of co-morbidity are seen with what other developmental disorders?
 3. Describe the language and cognitive characteristics of children with Fragile X. What are the implications for assessment and treatment?
- III. DLD Associated with Sensory Impairments
 - A. Visual impairment
 1. How does blindness affect language development in terms of language form, content, and use?

TABLE 4-4 Cognitive and Language Characteristics across Diagnostic Categories

	Nonverbal Cognition	Executive Functions	Working Memory
Primary DLD	Not usually impaired	Variable	Impaired
Down syndrome	Impaired	Impaired	Impaired
Williams syndrome	Impaired	Impaired	Impaired
Fragile X syndrome (males)	Impaired	Impaired	Impaired
Visual impairment	Not usually impaired	Not usually impaired	Not usually impaired
Hearing impairment	Not usually impaired	Not usually impaired	Not usually impaired
Traumatic brain injury	Variable	Impaired	Impaired
Focal brain lesions	Not usually impaired	Not usually impaired	Variable
Landau Kleffner syndrome	Not usually impaired	?	Impaired
Autism spectrum disorder	Variable	Impaired	Variable
Attention-deficit hyperactivity disorder	Not usually impaired	Impaired	Impaired
Fetal alcohol syndrome	Mildly impaired	Impaired	Impaired
	Language Form	Language Content	Language Use
Primary DLD	Impaired	Relative strength	Relative strength
Down syndrome	Impaired	Relative strength	Relative strength
Williams syndrome	Not usually impaired	Relative strength	Impaired
Fragile X syndrome (males)	Impaired	Impaired	Impaired
Visual impairment	Not usually impaired	Relative strength	Vulnerable
Hearing impairment	Variable	Not usually impaired	Relative strength
Traumatic brain injury	Variable	Relative strength	Vulnerable
Focal brain lesions	Not usually impaired	Relative strength	Relative strength
Landau Kleffner syndrome	Impaired	Impaired	Vulnerable
Autism spectrum disorder	Variable	Relative strength	Impaired
Attention-deficit hyperactivity disorder	Variable	Relative strength	Vulnerable
Fetal alcohol syndrome	Variable	Impaired	Vulnerable
	Delayed Language Onset	Decoding (Non-Word Reading)	Reading Comprehension
Primary DLD	Yes	Vulnerable	Impaired
Down syndrome	Yes	Vulnerable	Impaired
Williams syndrome	Yes	Impaired	Impaired
Fragile X syndrome (males)	Yes	Impaired	Impaired
Visual impairment	Yes	Alternative method	Alternative method
Hearing impairment	No, if deaf parents	Vulnerable	Variable
Traumatic brain injury	No	Vulnerable	Impaired
Focal brain lesions	Yes	?	?
Landau Kleffner syndrome	No	May be strength	May be strength
Autism spectrum disorder	Yes	Variable	Impaired
Attention-deficit hyperactivity disorder	Maybe	Variable	Variable
Fetal alcohol syndrome	Maybe	Vulnerable	?

2. How can clinicians support literacy development in children with visual impairment?

B. Hearing impairment

1. Otitis media

- Discuss the effects of otitis media (OM) on communication development.
- What clinical implications can be drawn from the research on OM and language disorders?
- What other developmental disorders are associated with high rates of OM?

2. Sensori-Neural Hearing Impairment

- Define the types and degrees of hearing loss.
- How have cochlear implants (CI) changed the role of speech-language pathologists?

- Describe the differences in language form, content, use, and literacy for children with sensorineural hearing impairment (HI).

- What are the effects of CI on language and literacy outcomes for children with HI?

C. Auditory processing disorder

- Is auditory processing disorder (APD) a valid diagnostic entity? Explain your answer.
- Discuss the guidelines for assessment of APD.

IV. DLD Associated with Acquired Neurological Disorder

A. Traumatic Brain Injury

- Describe the three phases of recovery from traumatic brain injury (TBI) and the assessment/intervention approaches most appropriate for each phase.

2. Discuss the cognitive impairments associated with TBI, and their implications for learning and language processing.
3. What issues do clinicians need to consider when reintegrating children with TBI into the mainstream classroom?
- B. Focal brain lesions
 1. What is the pattern of language development and disorder in children with early acquired focal brain lesions?
 2. What language skills are most vulnerable in children with focal lesions?
- C. Seizure disorders (Landau Klefner Syndrome)
 1. What are the developmental characteristics of Landau Klefner Syndrome (LKS) that should alert the clinician to consider this diagnosis?
 2. Discuss language form, content, and use in children with LKS.
 3. What alternative methods of communication have been suggested for use in LKS?
- V. DLD Associated with Psychiatric Disorders
 - A. Autism spectrum disorder
 1. What are the key diagnostic features of autism spectrum disorder (ASD)? How do the new severity criteria help clinicians?
 2. Describe the cognitive profiles of children with ASD.
 3. How might problems with social interaction and social understanding affect language development and language processing?
 4. Discuss the literacy skills of children with ASD.
 5. How are language form, content and use related in ASD?
 - B. Attention-deficit hyperactivity disorder
 1. What are the cognitive features of attention-deficit hyperactivity disorder (ADHD)? How might they influence language development?
 2. What additional factors should the clinician consider when developing intervention programs for children with ADHD?
 - C. Selective mutism
 1. What are the diagnostic criteria for children with selective mutism?
 2. Discuss some strategies for working with children who have selective mutism?
- VI. DLD Associated with Environmental Disadvantage
 - A. Maltreatment
 1. Why are children with language disorders at increased risk for maltreatment?
 2. How does maltreatment affect communication development?
 3. What are some of the implications for intervention with children who have been maltreated?
 - B. Fetal alcohol spectrum disorder
 1. Describe the physical and cognitive characteristics of children with fetal alcohol spectrum disorder (FASD).
 2. How does FASD interact with other environmental risks for DLD?
 3. Describe the language profiles of children with FASD. Which aspects of communication are most vulnerable?
- VII. The Nonverbal Child
 - A. Describe different types of augmentative and alternative communication (AAC) systems. What are the pros and cons of each?
 - B. Will the use of AAC help or hinder spoken language development? Explain your answer.
 - C. Describe a literacy program for children using AAC. What special considerations need to be made in developing the program?
 - D. Explain the developmental sequence for social-communicative goals of intervention programs for nonverbal children with ASD.
- VIII. General Questions
 - A. What other professionals might the SLP be working with when assessing and treating children with developmental disorders?
 - B. How can language interventions influence the development of literacy skills in these populations?
 - C. Executive function deficits are reported in a number of developmental disorders. What are they and how might they influence language development and language processing?
 - D. What is the role of parents in developing and implementing intervention? Is it different for different disorders?

Child Language Disorders in a Pluralistic Society

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Describe the distinction between language disorders and language differences.
2. Discuss the role of communication in culture.
3. List a range of assessment procedures for evaluating communication in children with cultural and linguistic differences.
4. Describe intervention issues and strategies for clients with cultural and language differences.
5. Discuss the role of the speech-language pathologist in addressing communicative competence in bilingual and bidialectal clients.

In his book on the Civil War, James McPherson (1988) recounted an episode that occurred during General Lee's surrender to General Grant at the Appomattox Courthouse. General Grant's staff included a Native American of the Seneca tribe, by the name of Ely Parker. General Lee, upon being introduced to Parker, noticed Parker's Native American features and remarked, "Well, it's nice to see a real American here." And Parker replied, "We are all Americans." (p. 849)

Unless you've been stranded on the space shuttle for the past decade, it must be obvious that the cultural composition of American society is changing. Sources of this change include an increase in immigration from Africa, Central and South American countries, the Caribbean Islands, and many parts of Asia and the Pacific Rim, as well as an increase in internal migration of Native Americans away from reservations toward metropolitan areas. A second source of the change is seen in the fact that, although the overall percentage of children in the United States is declining, the proportion of children from nonwhite, non-Western European, non-English-speaking backgrounds is increasing (Children's Defense Fund, 1990; Hobbs & Stoops, 2002; U.S. Census, 2008). This is a result both of higher birth rates in non-European and non-American populations (National Center for Health Statistics, 1985) and of the higher number of females of child-bearing age in these groups, relative to the European and American populations (Hanson, 1998; Hobbs & Stoops, 2002). The result of these trends is that one in every four people in the United States is now of a race other than white. In some states, such as California and Texas, a majority of residents are of a non-European background. By the year 2050, it is predicted that the percentage of individuals from non-European

backgrounds will increase, as the percentage of whites declines to slightly over half of the population (Goldstein & Iglesias, 2006). In some cities, such as Miami, Philadelphia, and Baltimore, "minority" children are a majority in the public schools (Adler, 1993; Brice, 2002). But as Goldstein and Iglesias (2006) point out, there is a misperception that individuals from culturally and linguistically diverse populations exist mainly in large, urban areas. Children from culturally and linguistically diverse populations are well represented across the nation's school systems. In 2006–07, approximately 24% of all public school students attended schools where the combined enrollment of Black, Hispanic, Asian/Pacific Islander, and American Indian/Alaska Native students was at least 75 percent, compared with 16 percent of public school students in 1990–91 (Planty et al., 2009), and 40% of children in U.S. schools were from culturally and linguistically diverse backgrounds. The U.S. Department of Education estimates that 20% of students are learning English as a second language. And, unfortunately, a disproportionate number of these children will be from poor, single-parent (usually single-mother) families and at risk for a variety of disabilities (Battle, 2002b; Brice, 2002; Hanson, 2004; Iglesias, 2001), while only 6.9% of all speech-language pathologists (SLPs) are members of a racial minority, compared to 24.9% of the U.S. population (American Speech-Language and Hearing Association [ASHA], 2009).

And yet, as Ely Parker so aptly observed, we are all Americans. This is the challenge that SLPs face in this century: to appreciate the vibrant possibilities of the diversity that makes up our multifaceted American civilization and to contribute to our clients' ability to participate in it. Appreciation entails understanding, sensitivity, and respect for the many ways people look at the world and use communication, given their differences in culture and experience. Contributing means that we use every tool available to ensure that all clients—regardless of cultural background—get the most informed, most effective assessment of their difficulties and the most efficient, sensitive support in maximizing their potential for successful communication.

The term *culture* refers to the ways of thinking, talking, understanding, and relating to others that are characteristic of groups of people with a shared history. Cultures evolve to serve a purpose: to make groups coherent and to preserve their values and beliefs over time. In general, people come to America because they want a better life for themselves and for their children. Some come to escape repressive or intolerant societies in their homelands. Others want a chance to participate in our prosperity and engage in our pursuit of happiness. However, the opportunity to participate in the economic and political freedom that America affords should not have to entail giving up all that was unique about the cultures from which

each American came. For all of us, the achievement of participation in mainstream American life is a tug-of-war between opposing aspirations—the desire, on one hand, to enjoy the benefits of engagement in the wider society and the need, on the other hand, to maintain our cultural heritages and links to our past and our roots.

As clinicians, we help balance these desires by trying to provide access, through effective communication, to the opportunities of American society without depriving clients of the communication styles and strategies of their home cultures. This approach is often called “bicultural” education. Bicultural education simply means that a person can learn to take part in two (or more) sets of cultural styles and can switch back and forth when appropriate to maximize effectiveness in each. The foundation of bicultural education is understanding and sincere respect on the part of teachers and clinicians for cultures that contrast with those of the mainstream and that influence clients’ communication.

DEFINING LANGUAGE DIFFERENCES

We should focus here for a moment on the distinction between a language difference and a language disorder. A disorder is what we defined in Chapter 1: a significant discrepancy in language skills relative to what would be expected for a client’s age or developmental level. A language difference, on the other hand, is a rule-governed language style that deviates in some way from the standard usage of the mainstream culture. Some children from culturally different backgrounds have language disorders. When they do, the SLP’s job is to provide remediation in a culturally sensitive way. But many children from culturally different backgrounds who are referred for language assessment do not have disorders, only limited exposure and experience with the language of instruction. Some, for example, who are acquiring English along with a home language display a different language acquisition pattern than children who are monolingual (Marian, 2009). Others may have limited exposure and opportunities to use English, so that their English skills are not as advanced as their skills in the home language. Roseberry-McKibbin (2008) discusses this issue in some detail and provides a framework for conceptualizing the needs of children with cultural and linguistic differences (CLD) who have varying levels of language ability

and exposure to English. Table 5-1 provides an adaptation of her scheme.

Children can, of course, be at different stages along the road to being fully competent in English. Kohnert (2008) discussed the distinction between basic interpersonal communication skills (BICS) and cognitive academic language proficiency (CALP). These terms represent the two ends of a continuum of competence with a non-native language. Some English language learners (ELLs) will have limited English proficiency (LEP); they will have a hard time expressing very basic communicative functions in English (although they may do just fine in their home language). Some children will be at the BICS stage of English acquisition; they can use words that are frequent in the language, produce more or less grammatical sentences, and engage in everyday talk about familiar items and events. Cummins et al. (2006) estimates it takes a child 2 to 3 years of exposure to and experience with English to achieve BICS, although Roseberry-McKibbin (2008) reports the time can actually vary widely across children. When they do achieve BICS, children may appear to be fluent speakers of English, and may be thought to be fully bilingual. But Hornberger and Cummins (2008), Kohnert (2008), and Roseberry-McKibbin (2008) remind us that this level of language proficiency is often not enough to succeed in the classroom, especially after the primary grades. BICS gets a child by on the playground. But to be able to read higher level texts with adequate comprehension, produce a range of written discourse, use and understand subject-specific vocabulary, and engage in cognitively demanding communication, BICS is not enough. To achieve CALP, which enables these kinds of higher-level communication skills, takes much longer. Cummins et al. (2006) estimate at least 5 to 7 years and sometimes longer. Because BICS may make a child appear to speak English, yet does not support success in the academic curriculum, children at BICS levels of English skill may appear to have language-learning disorders. We’ll talk later about how to use assessment techniques to determine whether deficits in CALP represent language-learning difficulties or are rather a result of incomplete acquisition as seen in BICS. For now, it is important to know that the BICS/CALP distinction can make distinguishing language disorders from language differences challenging in ELLs. Still, one of the primary jobs of the SLP in dealing with children from CLD backgrounds is to accurately diagnose language disorders and distinguish them from language differences.

TABLE 5-1 Needs of Children with CLD and Varying Combinations of Language Learning Ability and English Exposure

Exposure to English	Language Learning Ability	
	Typical	Language Learning Disability
Adequate	Bilingual Education or Sheltered English instruction or ESL instruction	Bilingual special education or English special education with language input in primary language from educational aides, volunteers, etc.
Limited	Bilingual Education or Sheltered English or ESL and Addition opportunities to use English (tutoring, RTI, social skills group, English speaking “buddy” time	Bilingual special education or English special education with language input in primary language from educational aides, volunteers, etc. and Addition opportunities to use English (tutoring, RTI, social skills group, English speaking “buddy” time

Adapted from Roseberry-McKibbin, C. (2008). *Multicultural students with special needs*. Oceanside, CA: Academic Communication Associates.

Cultural sensitivity is needed when working with families whose backgrounds differ from the clinician's.

When careful assessment, such as the kind described later in this chapter, reveals a difference rather than a disorder, Roseberry-McKibben (2008) suggests “sheltered English instruction.” In sheltered English instruction academic content is taught in English, but the input language is simplified and supports, including visual and graphic organizers, relating to students’ personal experiences, and supplementary culturally familiar materials are used (these supports are likely to help many students in the classroom, not only English language learners!). Kohnert et al. (2005) also discuss strategies for supporting the acquisition of home language of CLD children, as a solid foundation for the development of CALP skills. We’ll talk about developing both BICS and CALP levels of Standard English proficiency in the intervention section of this chapter.

First, though, let’s look at few of the larger cultural groups likely to be encountered in language pathology practice with children. We’ll talk first about some information useful in understanding the communication patterns of children from some of these minority groups. Additional information is available in Roseberry-McKibbin (2008). Then we’ll look at some of the tools we can use to provide the most effective assessment and intervention services to these children.

LARGER MINORITY GROUPS IN AMERICA’S CULTURES

African-American Culture and Communication

As Terrell and Jackson (2002) pointed out, African-Americans, currently almost 13% of the U.S. population (U.S. Census Bureau, 2010), are not all alike. Some are wealthy, some are poor, and some are middle class. Socioeconomic class makes a good deal of difference in the attitudes and experiences of African-Americans, as it does in all Americans. However, one set of cultural experiences is common to many African-Americans: the history of forced abduction from their homelands, of slavery, and the tradition of racism and discrimination that has existed in the United States. Terrell and Terrell (1996) argued that the reaction to this set of experiences has formed many of the elements of contemporary African-American culture, including its music, religion, attitudes, and communication styles. Moreover, these experiences, according to Terrell and Terrell (1996), have led many African-Americans to develop a

sense of cultural mistrust that can affect their performance on evaluations administered by white clinicians. Willis (2004) provides additional information on cultural features that were shaped by these experiences and are shared by families with African-American roots.

The communication style shared by many, though not all African-Americans, is often called African American English, or AAE (Craig & Washington, 2006). AAE is considered a *dialect* of American English. Dialects are regional or cultural variations within a language that are used by a particular group of speakers. It shares many features with Standard American English (SAE; Craig and Washington, 2006). Dialects use a set of rules that are similar in many ways to those of the standard form of the language but differ in the frequency or circumstances of use of certain structures, lexical items, and other elements. All dialects of a language are mutually intelligible—any speaker of the language can understand them—and all are equally complex and legitimate (Burns et al., 2010). But some dialects have a higher status than others. The relative value or status of dialects is not inherent, though. It is said that a *language* can be defined as “a dialect with an army and a navy.” In other words, the choice of which dialect has the role of the “standard” form of the language has more to do with power relations within the society than with anything intrinsic to the linguistic structure of any of the dialects involved.

Speaking a nonstandard dialect does not, in itself, constitute a disorder, but merely a difference in language use (Seymour, 2004). Still, the use of a nonstandard dialect such as AAE can in some situations be a handicap to the user, if speakers of the standard dialect view the nonstandard form as inferior or deviant (Fitts, 2001). Terrell and Terrell (1983), for example, found that when two groups of equally qualified African-American women applied for secretarial jobs advertised in newspapers, applicants who spoke AAE were less likely to be offered jobs. When they were, significantly lower salaries were offered to AAE speakers than to speakers of SAE. Prejudice against speakers of AAE, then, can have important economic implications.

Not all African-Americans use AAE, and many who do are bidialectal. In addition, the degree to which dialectal features are present in the speech of AAE speakers varies (see the Dialect Density Measure by Craig, Washington, & Thompson-Porter, 1998). Some speakers, even as young as preschool age, use AAE, for example, at home and with friends and switch to SAE, or whatever the predominant regional dialect of the mainstream is, when operating in less familiar settings (Connor & Craig, 2006). Use of AAE varies, to some extent, with geographical region (Stockman, 2010). Washington and Craig (1992), for example, found that AAE speakers living in the urban Midwest did not use as many AAE changes in their phonology as did children from the South. The use of AAE changes over a person’s lifetime, as well (Craig & Washington, 2006). Craig, Thompson, Washington, and Potter (2003) and Issacs (1996) found that use of nonstandard dialect decreased through the elementary school grades, with the biggest dip occurring between kindergarten and first grade (Craig & Washington, 2006). AAE use also differs across contexts: Thomson, Craig, and Washington (2004a) found that African-American third graders used less AAE in more literate contexts, such as writing, than in picture description, while Curenton and Justice (2004) found that African-American preschool AAE speakers used literate language forms as often as Caucasian peers in a story-telling task from a wordless picture book. However, some African-Americans live in relatively isolated settings and may have little exposure to Standard English (Willis,

2004; Wolfram, Hazen, & Tamburro, 1997). Despite the great variability in its use (Burns et al., 2010), however, some characteristic differences between AAE and SAE are useful for clinicians to know. These differences are summarized in [Box 5-1](#). For more detailed information on the linguistic structure of AAE, Charity (2008); Craig and Washington (2006); Green (2002); Mufwene, Rickford, Baugh, and Bailey (1998); Rickford (1999); and Roseberry-McKibben (2008) are excellent resources.

Understanding these characteristics can help the clinician to communicate more effectively with African-American clients, to distinguish between a difference and a disorder, and to identify points of interference with achievement in the curriculum. It also is helpful in this enterprise to understand the normal sequence of acquisition in AAE, which is described in Craig and Washington (2002, 2005); Horton-Ikard and Weismer (2005); Jackson and Roberts (2001); and Kamhi, Pollack, and Harris (1996).

As we'll often see in this chapter, supporting dialect speakers in their development of literacy and academic skills does not mean that the home dialect, in this case AAE, is defective in any way or that the AAE speaker has a disorder. It only means that we want to provide access to the language skills needed to succeed in the academic curriculum and to avoid encountering bias in the mainstream culture. Of course, we never want to "extinguish" use of AAE; rather, our goal is to develop bidialectal individuals who can *code switch*, or move back and forth, between AAE and SAE, as appropriate to the situation.

Hispanic-American Culture and Communication

Americans of Hispanic heritage come from a variety of cultures and races. What they share is a background of Spanish-speaking ancestry, although they may not actually speak Spanish themselves. Hispanic-Americans (or *Latinos*) come from Mexico, Cuba, Puerto Rico, Spain, the Caribbean Islands, Central and South American countries, and even Asia or Africa, and account for 16% of the U.S. population (U.S. Census Bureau, 2010). This diverse group speaks many dialects of Spanish; the major five spoken in the United States are Mexican, Central American, Caribbean, Chilean, and Puerto Rican. Some Hispanics are monolingual Spanish speakers; others are bilingual, to one degree or another, in English and Spanish. Brice (2002), Goldstein (2001, 2004), Roseberry-McKibben (2002a), and Zuniga (2004) provide detailed information about many aspects of the Latino culture of these diverse peoples.

Many children of Hispanic heritage come to school with *limited English proficiency (LEP)*; that is, they know a little English but are not fluent communicators in English and have trouble functioning in a monolingual English classroom, at least for a while. These children are often referred to as English Language Learners (ELLs). Again, LEP is not a disorder, nor is it a permanent condition. Most normally developing children, with help and opportunities to interact with peers, eventually master English and become bilingual, able to communicate effectively in two languages.

BOX 5-1 Some Differences between AAE and SAE

PHONOLOGICAL DIFFERENCES

Changes in Medial and Final Consonants

1. Voiced and voiceless *th* replaced (*toof* for *tooth*; *nofin* for *nothing*).
2. /r/ and /l/ deleted (/fo/ for *four*; *potect* for *protect*).
3. Voiced stops; /b/, /d/, and /g/ devoiced with vowel lengthened in consonant-vowel-consonant words (/plk/ with lengthened vowel for *pig*).
4. /m/ and /n/ deleted and replaced by a nasalized vowel (/pĩ/ with nasalized vowel for *pin*).
5. /ŋ/ changed to /n/ in -ing forms.
6. Change in order of consonants in cluster (/æks/ for *ask*).

Changes in Initial Phonemes, Syllables, and Initial Consonant Blends

1. Liquids often dropped from initial consonant blends (/p/ for *pr*; /b/ for *br*, etc.).
2. Certain consonants (particularly /w/ and /d/) omitted in specific words (*was*, *one*, and *don't*); final /r/ deleted.
3. Unstressed initial syllables dropped (*mato* for *tomato*, *cause* for *because*).
4. Word initial interdental fricatives; (*th*) replaced by stops.
5. *Thr* clusters pronounced as *th* (*tho* for *throw*).

Deletion of Final Consonants and Clusters

1. Final consonant is dropped in final clusters such as /nd/, /sk/, /sp/, /ft/, /ld/, /st/, /sd/, /nt/.
2. Variable deletion of certain consonants, including /l/, /b/, /p/, /d/, /t/, /g/, /k/.

SYNTACTIC AND MORPHOLOGICAL DIFFERENCES

Verb Marking

1. Regular past tense marking (-ed) is not obligatory and is sometimes omitted.
2. Irregular past tense is marked on some verbs and not on others (see is not changed to *saw*).
3. Regular and irregular third-person marking is not obligatory.
4. Future tense is often marked by *gonna* rather than *will*. When *will* is contracted, its pronunciation may be reduced. When *will* is required before *be* in SAE, it may be deleted in AAE ("I be home later" instead of "I will be home later"); or *bouta* (He *bouta* fall).
5. Contractible forms of copula and auxiliary *be* verbs are not obligatory ("He here"), though contractible forms are obligatory ("Is he here?").
6. Perfect tense in AAE is expressed by *been* to denote action completed in the distant past ("She *been* gone"); SAE uses adverbs to express this idea ("She *left long ago*").
7. Habitual state of verbs is marked with uninflected *be* in AAE ("She be workin' two jobs"), whereas SAE uses adverbs and inflected forms of *be* ("She's working two jobs now").
8. Double modals are allowed in AAE ("We might could go"), but not in SAE.

BOX 5-1 Some Differences between AAE and SAE—cont'd**Noun Inflections**

1. Plurals are not obligatory when quantifiers are present (*two dollar*).
2. Possessives are not obligatory when word order expresses possession ("Get mother coat"; "It be mother's").

Pronouns and Demonstratives

1. Pronominal apposition (noun followed by pronoun) is used in AAE ("My mother she home").
2. Reflexive pronoun forms are regularized in AAE so that all reflexive forms are produced by adding *-self* to a possessive pronoun (his-*hissself* in AAE, but *himself* in SAE; their-*theirself* in AAE, but *themselves* in SAE).
3. Relative pronouns are not obligatory in most cases, although in SAE only the *that* form is optional (AAE: "He the one made it"; SAE: "He's the one *who* made it"; but SAE: "He's the one [that] you like").
4. *These here* and *them there* combinations used in AAE, but not in SAE.
5. *Them* substituted in AAE for forms used in SAE (*these, those*).

Comparative and Superlative Markers

1. Endings *-er* and *-est* can be added to most adjectives in AAE (*baddest, worser*), unlike in SAE in which only certain forms can take these endings.
2. *More* and *most* can be combined with superlative comparative markers in AAE (*most stupidest*).

Negation

1. Double- and triple-negative markers may be used in AAE ("Nobody didn't never write to me"), but not in SAE ("Nobody ever wrote to me").
2. *Ain't* is used as a negative marker in AAE.

Questions

1. Indirect questions are produced with the same form as direct questions in AAE ("What is it?" "Do you know what is it?").
2. A clause beginning with *if* in SAE is produced with *do* in an indirect question in AAE ("I want to know *do* you want to play ball with us?").

SEMANTIC DIFFERENCES

Many lexical items are used in AAE that are not used in SAE or that come into SAE from their use in AAE. Some examples include *funky* and *rap*. Other words are used to denote meanings in AAE that are not part of their meaning in SAE, although often these meanings migrate into mainstream use as well. Some examples are *hog* (expensive car), *all that* (excellent), and *dude* (man or person).

PRAGMATIC DIFFERENCES

1. Silence is used in AAE when the speaker is in unfamiliar situations, when a speaker means to refute an accusation, or when a question considered intrusive is asked. The silence is often misinterpreted by mainstream listeners as a lack of innocence of an accusation or lack of knowledge, rather than as a communication strategy.
2. Direct eye contact is used in AAE in the speaker's role, but indirect eye contact is considered proper listening behavior. Making direct eye contact with speakers by children and by speakers with lower status is considered disrespectful in AAE. SAE speakers may misinterpret the indirect eye contact as "not listening" or "not making appropriate eye contact."
3. Wit and sarcasm are important elements in AAE language interactions. These often involve ritualized insults and retorts. Skill at parrying in these interactions is highly valued. Such interactions, often perceived as hostile by SAE speakers, may in fact be friendly and playful.
4. Asking personal questions of a new acquaintance about his or her job, family, and similar matters is considered rude and intrusive in AAE, although an SAE speaker may intend such inquiries to be friendly.
5. Conversations are considered private; butting in is seen as rude in AAE, although SAE speakers may intend this behavior to be a helpful addition to the discussion.
6. Interruption is tolerated and access to the conversational floor is given to the most aggressive speaker in AAE, whereas in SAE turn-taking rules attempt to give most participants at least some time to hold the floor, and interruption is considered rude.
7. Dynamic, intense behavior in public conversations in AAE is acceptable, including intense verbal arguing; SAE requires more restraint, less emotion, and less intensity in verbal argument.
8. Narrative style in AAE may differ from mainstream styles in that
 - More gestures are used
 - Judgments and evaluations of characters may be included
 - More associational styles are used, rather than topic-centered styles, which are typical of SAE. AAE narratives flow from comments made in association with the last statement, rather than from a central theme.
9. Touching a child's hair during conversation is considered an insult in AAE, whereas in SAE it is meant as a sign of affection.

Brice (2002); Brice and Brice (2007); Gildersleeve-Neumann, Kester, Davis, and Peña (2008); Haynes and Shulman (1998a); Kayser (2002); Scheffner Hammer, Miccio, and Rodriguez (2004); Tabors, Paez, and Lopez (2002); and Uccelli and Paez (2007) provide a detailed discussion of what is known about normal development of Spanish in children learning it as a first language. This information can be useful to clinicians attempting to differentiate between a language difference and a disorder in a child whose dominant language is Spanish. When looking at the Spanish language development of these children, comparing production to available information on

normal acquisition of Spanish can help to establish the stage of development a child is demonstrating in the first language. We'll talk in more detail later in the assessment section about some methods of looking at level of first language acquisition in children with LEP.

In working with Hispanic children with LEP, some characteristic difficulties or interference points come up between English and Spanish in what we might call Spanish-influenced English (SpIE). These characteristics are summarized in [Box 5-2](#). Hispanic children with LEP who make changes such as those listed in [Box 5-2](#)

BOX 5-2 Characteristics of Spanish-Influenced English

PHONOLOGY

1. Some phonemes of English are not used in Spanish and will typically be changed in SpIE:
 - /θ/ in English is changed to /t/ in SpIE.
 - /ð/ in English is changed to /d/ in SpIE.
 - /z/ in English is changed to /s/ in SpIE.
 - /j/ in English is changed to /tʃ/ in SpIE.
 - /v/ in English is changed to /b/ in SpIE.
 - /dʒ/ in English is changed to /j/ in SpIE.
2. Final consonants are usually devoiced in SpIE.
3. Addition of schwa vowel before /s/ initial consonant clusters in SpIE (*estudy* for *study*, *eschool* for *school*).
4. Spanish has fewer vowels than English. The vowels /I/, /æ/, and /ə/ are absent from Spanish and will be substituted for when they appear in SpIE. /I/ in SAE is usually pronounced as /i/ in SpIE, for example.

SYNTAX AND MORPHOLOGY

Verb Marking

1. Regular past *-ed* is not obligatory in SpIE.
2. Regular third-person-singular marking is not obligatory in SpIE.
3. Copula *will* sometimes be produced as *have* in certain constructions ("I *have* eight years").
4. Future tense can be expressed by "go + to" in SpIE (for example, SpIE: "I go to have lunch." SAE: "I am going to have lunch").

Noun Inflections

1. Possessive markers used in SAE will be substituted by prepositional phrases ("the book *of my sister*"), or, in the case of body parts, by articles ("I cut *the* finger").
2. Plural /s/ marker is not obligatory in SpIE.
3. Articles are often omitted in SpIE ("I go to store").
4. Subject pronouns may be omitted in SpIE when the subject has been given in the previous sentence ("Jose is sick. Got chicken pox").
5. *More* is used as a comparative marker in SpIE instead of the *-er* ending ("He is more short").
6. Articles are optional ("That is big dog").

Negatives

1. *No* may be used in SpIE as a negative marker in place of *not* ("She no go to work today").
2. *No* may be used instead of *don't* in negative imperatives ("No go too fast!").

Questions

1. "Do insertion" is not obligatory in questions in SpIE (SpIE: "You want some?" SAE: "Do you want some?").
2. Intonation is used more frequently in SpIE to mark questions than it is in SAE ("Carmen will be here?").

SEMANTICS

1. Number, color, and letter words often receive less emphasis in parent-child interactions in Hispanic households.
2. Names and labels for objects, donors of objects, and particularly for relatives are emphasized in Hispanic parent-child interactions.

PRAGMATICS

1. Speakers of SpIE tolerate closer personal distance during conversation than speakers of SAE.
2. Direct eye contact is avoided in SpIE; lack of eye contact can signal attentiveness in SpIE, although it can mean just the opposite in SAE.
3. There is a greater incidence of touching between conversational partners.

Data from Brice, A., & Brice, R. (2007). A tale of two languages. *The ASHA Leader*, (September, 2007); Kayser, H. (2002). Bilingual language development and language disorders. In D. E. Battle (Ed.), *Communication disorders in multicultural populations*, (3rd ed., pp. 205-232). Boston: Butterworth-Heinemann; Goldstein, B. (2001). in their use of English would not be considered as having a disorder. To determine whether a Hispanic child with LEP was having inordinate problems in learning English, we would need to look for other types of errors that would not be typical of SpIE. We'll talk in more detail in the assessment section about methods of looking for these atypical kinds of errors.

Native American Culture and Communication

Joe and Malach (2004) reported that at the time of Christopher Columbus, there were at least 1000 Native American tribal entities, each with a distinct language, culture, set of beliefs, and governance structure. Even though many Native Americans have moved away from reservations to more urban areas, more than 1 million people still live on hundreds of reservations located in remote rural areas where medical, educational, and rehabilitative services are not readily available. Even Native Americans in cities share many of the cultural and child-rearing practices of their relatives on reservations (Joe & Malach, 2004; Westby & Vining, 2002). Like the other cultural groups being discussed, the Native American population encompasses great diversity. However, Joe and Malach (2004) and Robinson-Zanartu (1996) have pointed out some of the common themes among communication styles of the many first American peoples.

Native American children from a variety of tribal groups have been found to score higher on motor, social, and self-help skills than their mainstream peers, although they score lower on language areas (Westby, 1986, 2005). These differences are thought to reflect the experience of the Native American children, whose cultures rely much more heavily on visual than on vocal channels of information exchange. Native American children are taught to learn by watching—being quiet, passive observers of cultural practices. Demonstration of skills to Native American children does not usually involve verbal accompaniment nor are children expected to show their knowledge by verbal performance. Instead, they are required to display their physical mastery of a task, such as dancing or weaving, by just doing it. Still, these cultural differences can have educational implications; children from Native American backgrounds are over-represented in special education (NCES, 2005), partly as a result of their tendency to “do” rather than talk.

Basso (1979) reported that Apache children were scolded for “acting like a white man” if they talked too much. Native American children are taught that important questions deserve thoughtful answers and are encouraged to take time to consider a question carefully before answering. The long pauses they use before responding to questions are often misinterpreted as a processing problem or lack of knowledge of the correct answer. Similarly, Joe and Malach (2004) report that it is considered rude in many Native American cultures to ask too direct a question or to make direct eye contact with one in authority. Westby (1986) emphasized that a Native American child's reluctance to speak, to look at the teacher, to ask questions, or a tendency to have long latency of response should not be misinterpreted as a lack of communicative competence. Instead, it should be understood as an appropriate expression of cultural patterns of communication (See Inglebret et al., 2008, for ways to use Native American storytelling traditions to encourage shared storybook reading).

Robinson-Zanartu (1996) noted that many Native American languages do not have words for concepts such as *hearing loss*, *retardation*, or *disability*. Nichols and Keltner (2005) report that

children so labeled by the mainstream culture may be considered as simply part of the traditional community by its members. This can have profound effects on the ways professionals need to communicate with families about assessment and intervention services.

Reid (2000) and Westby and Vining (2002) identified several general differences that are commonly seen between English and Native American languages, and give some examples, primarily based on the Navajo language, as reported by Young (1967). These are summarized in Box 5-3. For more detailed and specific comparisons, clinicians will need to consult native speakers of the languages with which they come in contact, or resources such as Mithun (1999) and Patrick (2002). Again, in analyzing the language skills of a Native American child with LEP and attempting to decide whether a language difference or disorder exists, it will be necessary to determine whether the errors made in the child's use of English are different or more pervasive than those of peers at similar stages of exposure to English. It also will be important to keep pragmatic differences in mind. Being sensitive to these differences will optimize the chances of obtaining information that is truly representative of the child's communicative competence. Inglebret and Harrison (2005) offer general considerations to SLPs for working with Native Americans. Faircloth and Pfeffer (2008) talk about collaborating with tribal communities to provide early intervention services to Native American children.

Arab-American Culture and Communication

Since the 1980s many new immigrants to the U.S. have come from the Arab world of Middle-Eastern countries including Egypt, Iran, Iraq, Syria, Turkey, and Algeria. Ninety-two percent of this population is of the Muslim faith, but the Arab language also provides a bond among peoples of this region (Roseberry-McKibben, 2008). Middle Eastern communication styles include the acceptance of loud speech as normal in conversation, rapid speech, emphasis on eye contact as indicative of truthfulness in men, though less acceptable for women, acceptance of emotionality in conversation, and value placed on silence during communication. Arabic cultures place high esteem on poetry and eloquence, as well as on elaborate displays of respect through the use of titles in greetings (Omar Nydell, 2006). Some articulation and language differences between English and Arabic speakers are listed in Box 5-4. Children from Middle-Eastern background who make these kinds of errors will need additional opportunities to hear and use English, in order to refine their English-language skills.

Asian-American Culture and Communication

Although Asians have been coming to America for more than two centuries, their numbers have increased greatly in the past three decades. Chan and Lee (2004) and Cheng (2001, 2002a) discussed the diversity of peoples included in the “Asian-American” category and provided valuable information on many linguistic, social, religious, educational, and historical characteristics of the major cultural groups subsumed under the “Asian-American” umbrella. They come from China; Japan; Korea; India; Vietnam; Thailand; Cambodia (Kampuchea); Laos; and various Pacific Islands, including Guam, Samoa, and the Philippines. They speak hundreds of different languages—more than 80 languages are spoken in China alone. Asian-Americans come out of both rural and urban backgrounds and

BOX 5-3 Features of Native American Dialects of English**PHONOLOGY**

1. Native American dialects retain the phonemic patterns, phonological rules, and stress patterns of the tribal language. For example, the Navajo language does not use consonant clusters in syllable final position. Navajo dialects of English simplify these clusters.
2. Native American dialects retain intonation patterns of the tribal language. For example, Navajo uses particles rather than intonational contours to express questions, exclamations, and other forms. Navajo dialects of English may not include intonational changes to mark emotional overtones in speech.

SYNTAX AND MORPHOLOGY

1. Native American dialects carry over syntactic forms from the tribal language. For example, in Navajo, possession is expressed by personal pronouns prefixed to the possessed noun (*man his-boots*). Navajo dialects may include these rather than standard ('s) possessive markers.
2. Native American dialects carry over morphological rules from the tribal language. For example, in Navajo, opposites are not expressed morphologically, but rather with a standard negating or opposite marker:
Navajo dialect: agree-not agree; SAE: agree-disagree
Navajo dialect: tie-not tie; SAE: tie-untie
3. Constructions found in other nonstandard forms of English also can be found in Native American dialects (e.g. *ain't*, uninflected forms of *be*.)
4. Specialized meanings of negative markers may be used; e.g., "The man does not do anything like this" (implies women may do it) and "The man does not do nothing like this" (implies he does something else).

PRAGMATICS

1. Cultural norms dictate who may be addressed by whom and what is appropriate to discuss at what season of the year.
2. Silence is more than absence of speech. It is a rule-governed practice used to express respect, thoughtfulness, that the question is worthy of serious consideration, or that the situation is unfamiliar.
3. It is rude to tell someone something he or she already knows. For example, if a teacher asks a question to which the answer is obvious, she must already know the answer (e.g., the teacher holds up a picture of a dog and says, "What is this?"), and therefore the child may not answer.
4. Greetings are not always used when entering or leaving, out of a desire not to intrude or interrupt.
5. Tempo of speech is slower and more fluid than in SAE.
6. Native Americans show a preference for "hearing out" a whole story or discourse before any questions or discussion takes place.
7. It is rude to correct or interrupt a peer.
8. Narratives are discursive, circling around a central point, rather than proceeding directly to it.

Adapted from Reid, D.K. (2000). Ebonics and Hispanic, Asian and Native American dialects of English. In K. Fahey & D.K. Reid (Eds.) *Language development, differences, and disorders* (pp. 219-246). Austin, TX: Pro-Ed; Young, R. (1967). *English as a second language for Navajos: An overview of certain cultural and linguistic factors*. Washington, DC: Navajo Area Office, Division of Education, Bureau of Indian Affairs; Westby, C. & Vining, C. (2002). Living in harmony: Providing services to native American children and families. In D.E. Battle (Ed.), *Communication disorders in multicultural populations*, 3rd ed. (pp. 135-178). Boston: Butterworth-Heinemann.

adhere to a variety of religions, including Buddhism, Christianity, Confucianism, Hinduism, Islam, Shinto, Taoism, and various local animistic belief systems. Like many cultures, those from Asia have specific cultural practices and beliefs relating to child development and language learning that need to be addressed when working with these families (Johnston & Wong, 2002). Clinicians who find children from these groups on their caseload will benefit from reviewing Chan's, Cheng's, and Johnston and Wong's detailed descriptions.

Like the Native American languages discussed earlier, the Asian languages that can influence the speech of Asian-Americans are so many and diverse that it would be impossible to outline all the points of interference. Cheng (2001), Goldstein (2000), Owens (2005), and Reid (2000) provided some characteristics that Asian language speakers in America have in common. These are outlined in Box 5-5. Cheng (2002b) provides specific guidelines for assessing Asian-language speakers. Again, though, a clinician working with an Asian-American ELL child will need to get more specific information about the child's first language to determine the extent to which a child's communication problem represents a language

difference or a disorder in need of intervention. Hwa-Froelich, Hodson, and Edward (2002), for example, discuss this issue for Vietnamese; Jia and Fuse (2007) discuss it for Mandarin.

High- and Low-Context Communication

As we've seen from this brief review of some of the communicative characteristics of several of the larger minority groups in America today, there is nearly as much diversity within each group as there is between each and the mainstream. Knowing a little about communicative characteristics typical of particular minorities can be useful in sensitizing ourselves to differences we might expect, so long as we are careful not to stereotype anyone on the basis of cultural background. In addition to the commonalities that exist within each cultural group, some general tendencies in communicative style are common across traditional cultures. Awareness of the possibility of these differences, too, can help us to be cognizant of the cultural factors that operate when we assess and remediate communication skills in children whose cultural backgrounds and perspectives diverge from our own.

BOX 5-4 Language and Articulation Differences between English and Arabic

COMMON CHANGES	RESULTING ERRORS IN ENGLISH
Articulation	
/n/ for /ŋ/ substitution	/sɑn/ for <i>song</i>
/ʃ/ for /tʃ/	<i>shoe/chew</i>
/w/ for /v/	/wæn/ for <i>van</i>
/f/ for /v/	/dʌf/ for <i>dove</i>
/t/ or /s/ for /θ/	/mæt/ for <i>math</i> ; /sɔt/ for <i>thought</i>
/z/ for /ð/	/ʌz-ɪ/ for <i>other</i>
Epenthesis in triple consonant clusters	/waɪldʌli/ for <i>wildly</i>
Language	
Omission of possessive markers	That John hat; The name boy is . . .
Omission of plural morphemes	She has four dog.
Omission of prepositions	Put your socks.
Omission of <i>be</i> verbs	She my teacher.
Inversion of noun phrases	He go to the station gas.

Adapted from Omar Nydell, M. (2006). *Understanding Arabs: A guide for modern times* (4th ed.). Yarmouth, ME: Intercultural Press; Roseberry-McKibbin, C. (2008). *Multicultural students with special language needs*. Oceanside, CA: Academic Communication Associates.

SLPs will often have clients from cultural backgrounds different from their own.

Lynch (2004a) and Westby and Rouse (1985) discussed these general tendencies under the rubric of high-context versus low-context cultures, as defined by the anthropologist Hall (1983). Hall suggested that there is a continuum of contextualization of communication along which cultures can vary. Mainstream North American culture, particularly the culture of the classroom, tends toward the lowest end of this continuum, with communication being highly *decontextualized*. Many traditional cultures, however, locate their communication at the higher end of the contextualization continuum.

Table 5-2 presents some of the contrasts between high- and low-context communicative styles. Understanding these differences in communicative styles can help to head off problems with clients who come from relatively high-context cultures. We might, for example, talk about the objectives and procedures for the immediate present, perhaps one session at a time, in our discussions with these families and focus less on planning intervention strategies and goals for the longer-term future.

Westby and Rouse (1985) pointed out that children from more traditional, high-context cultures may have particular difficulty adjusting to the demands of low-context communicative situations, particularly those of the classroom. They suggested that SLPs, in a consulting role, can encourage teachers to incorporate some higher-context activities in programs designed for such children. These might include substituting a more high-context activity for the usual “sharing time” monologue required in typical classrooms. Instead of being asked to relate an experience without contextual support, children can be asked to respond as a group to a question about personal experiences, such as, “What happens when you have a guest in your home?” Rather than singling out a child, teachers can invite children to make a contribution when they have one and use the support provided by others’ contributions as a scaffold. Westby and Rouse (1985) also suggested supplying parents with a few low-context activities that they can do with the child at home. One idea might be to send home books at the child’s level for the parents to read to their children (or if they are unable to read English, to talk about the pictures with their children). Parents can be given a list of specific questions to ask the children about the books, such as, “What is the story about?” “How did the character feel?” and “Why did she do that?” Increasing the contextualization of some activities at school while providing some experience with decontextualized talk at home can help to ease the transition for children from more traditional cultures, especially children with language and learning difficulties.

Narratives

Another place in which high- and low-context cultural styles affect communication is the area of narrative development. Narratives differ from conversation in that they are monologues that are tied into cohesive units by linguistic markers and thematic unity. Like conversation, narratives are important communicative structures used by all cultures to accomplish specific communicative purposes. High- and low-context cultures differ in narrative style, though. They contrast in the degree to which the various narrative genres are used, in the way in which narratives are organized, and the extent to which children are expected to produce each genre. Goldstein (2000) and Heath (1986) described four basic narrative genres: recasts/recounts, event casts, accounts, and stories. Descriptions of each type are summarized in Box 5-6.

These genres are used for different purposes and to different degrees in high- and low-context cultures. High-context, traditional cultures expect children to use *recast/recounts* to retell events with extensive verbal imitation, role-playing, and use of present tense. Low-context cultures, such as those of the classroom, use them to summarize succinctly, using past tense. *Event casts* are used frequently in low-context cultures to explain activities or series of events that are being planned or will take place in the future. They are very prone to metalinguistic or metacognitive commentaries, in which the speaker talks about the language being used or thinks out loud about how best to convey the ideas. These types of narratives are used often in classroom communication but

BOX 5-5 Features of Asian Dialects of English**PHONOLOGY**

1. Most Asian languages have open (consonant-vowel) rather than closed (consonant-vowel-consonant) syllables. Many Asian dialects of English omit final consonants.
2. In many Asian languages, /r/ and /l/ occur in the same phonemic category and will be confused in Asia dialects of English.
3. Consonant blends are common in English but rare in many Asian languages. Some Asian-Americans may simplify them.
4. Many Asian languages are monosyllabic. Asian dialects of English may involve truncated or telegraphic-sounding forms, and stress may be misplaced.
5. Many Asian languages are tonal; prosodic changes carry semantic information rather than defining sentence types or conveying communicative intent, as they do in English. These intonational patterns may be difficult for Asian-Americans to learn, and they may be misinterpreted.

SYNTAX AND MORPHOLOGY**Verb Marking**

1. *Be* verbs may be omitted or improperly inflected ("I going" "I is going").
2. Auxiliary *do* may be omitted or uninflected ("He not going." "He do not go").
3. Past *-ed* may be omitted ("He want ice cream yesterday"), overgeneralized ("He eated the cake"), or doubly marked ("She didn't saw me").
4. Past participle may be unmarked ("I have eat") or overgeneralized ("He has wented"), *have* auxiliary may be omitted ("He been there").
5. Noun-verb agreement may be error ("He have"; "You goes").

Nouns and Pronouns

1. Plurals may be omitted with quantifiers (*two shoe*) or overgeneralized (*the sheeps*).
2. Subject-object confusion ("Him here").
3. Errors of possessive marking (*him book*).
4. Errors on demonstrative pronouns (*those horse*).
5. Errors on comparatives (*gooder, more gooder*).
6. Gender is not marked ("He and his husband go").

Negatives

1. Double marking ("I didn't hear nothing").
2. Simplified marker ("He no want").

Questions

1. No reversal of auxiliary verb ("you are going?").
2. Auxiliary omitted ("You like football?").

Other

1. Omission or misuse of prepositions ("She is at room." "We go car").
2. Omission of conjunctions ("You I leave now").
3. Omission or overinclusion of articles ("I got to store." "You go to the home").
4. Word-order errors including adjectives following nouns (*Shoe new*), possessive following nouns (*hat mine*), subject-verb-object order. ("He gave out them").

SEMANTICS

1. Literal translations from native language (*open-light=turn on light*).
2. Difficulties with idioms and colloquialisms.

PRAGMATICS

1. Giggling may be used to indicate shyness rather than humor.
2. Praise is responded to with embarrassment; praise is not usually give outside the family.
3. Feelings are not openly expressed; Asians may retain composed facial expression even when agitated. Reprimands may be responded to by lowering the eyes and maintaining silence.
4. Kinship terms may be used to address elders as sign to respect, even when they are actually related.
5. Professionals have high status and command respect. They are regarded as authorities.
6. Social status is important and must be established early in an interaction. Formal introductions by a third party are preferred to self-introductions, particularly for introduction of high-status professional (such as SLPs).
7. Social status is established on the basis of age, marital status, and employment. Questions on these facts are deemed appropriate to ask directly of new acquaintances to establish proper social order among conversationalists.
8. Children are expected to be seen and not heard; children are not expected to talk during meals. In schools, children are discouraged from interrupting teachers and may appear passive to Western adults.
9. Direct eye contact is avoided.
10. Repeated head nodding is used.
11. It is rude to say "no." It is hard for Asians to disagree directly, especially with a high-status professional.

TABLE 5-2 Contrasts between High- and Low-Context Communicative Styles

Low-Context Styles Used in Mainstream Culture	High-Context Styles Used In Traditional Cultures
Most information is transmitted verbally.	Most information is the physical context or is in shared knowledge among participants.
Learning takes place through words.	Routines and behaviors are taught through observation.
Society undergoes rapid change; there is great opportunity but life is less predictable. Planning of the future and delaying gratification for future rewards are encouraged.	Change is slow, life is predictable. As a result, little planning is needed. Talk about the future may be discouraged.
The role of the individual is to achieve and excel.	The role of the individual is as a member of the cultural group; most activities are controlled by the group rather than by an individual; individuals should not stand out from peers.
Monochronic concept of time: Single events happen one at a time. Planning and scheduling are critical.	Polychronic concept of time: time is flexible; timelines and schedules may not exist. What matters is the completion of transactions, not time.
Actions are tightly scheduled. What matters is sticking to the timetable.

BOX 5-6 Narrative Genre Descriptions

Recast/Recount—Retells events and experiences from the past, with sequential chronology and consistent point of view. Example: summarizing a section of a textbook.

Event cast—Verbal replies or explications of activities or procedures that are currently being done or are planned. Example: telling how to bake a pie, explaining what will happen on a field trip.

Account—Shares an experience. Example: telling about your vacation.

Story—Fictional account of people (or animals or inanimate objects that take on human characteristics) who must overcome some problem that has social or moral significance to the culture. Example: *The Three Little Pigs*.

Adapted from Goldstein, B. (2000). *Cultural and linguistic diversity resource guide for speech-language pathology*. San Diego: Singular Publishing Group; Heath, S. (1986). Taking a cross-cultural look at narratives. *Topics in Languages Disorders*, 7(1), 84-94; Kayser, H. (2002.) Bilingual language development and language disorders, in D.E. Battle (Ed.), *Communication disorders in multicultural populations* (3rd ed.) (pp. 114-157). Boston. Butterworth-Heinemann.

are rarely expected of children in high-context, traditional cultures. *Accounts* are used in both high- and low-context cultures to share experiences. Low-context cultures require that they have a predictable progression of events so that the listener can anticipate what is coming. In low-context situations in which these narratives are used, such as the show-and-tell situation in school, accounts are judged by not only their truth value but also by their degree of organization. In high-context cultures, less stress is on organization. *Stories* are used by both high- and low-context cultures, but they differ across cultures in terms of their internal organization and focus. Although most cultures expect children to listen to stories, cultures differ in the degree to which children are expected to tell stories. In some traditional high-context cultures, only elders or others with high status are expected to be storytellers.

Goldstein (2000) and Hester (1996) discussed the different structures that stories can have in high- and low-context cultures. Low-context cultures tend to have a storytelling style that Gee

(1985), Michaels and Collins (1984), and Tannen (1982) referred to as “topic-centered.” These stories have a linear progression that follows the story-grammar model (Stein & Glenn, 1979), in which an initiating event or problem motivates a character to develop a plan and carry out an attempt to solve the problem. The problem is resolved one way or another, and some form of external evaluation of the resolution (“and they lived happily ever after”) takes place. (Story grammars are discussed in more detail in Chapters 10 to 14.) High-context cultures tend to use a more topic-associated style of narrative organization. This style is more anecdotal than linear. Westby and Vining (2002) reported that topic-associated stories consist of segments in which the overall theme may be implicit but never stated. Focus of person, place, and time often shifts and relationships must be inferred by the listener. These stories are longer than topic-centered narratives and may appear to the naive listener to have no beginning, middle, end, or central point. Westby (1989a) cited Kaplan’s (1966) diagrammatic representation of the different forms that topic-associated narrative can take. These appear in Figure 5-1. However, Goldstein (2000) pointed out that this difference in structure may be more related to task demands than to underlying narrative ability. In fact, Fiestas and Peña (2004) found that bilingual children did include elements of story grammar in their stories in both English and Spanish, although there were differences in the particular elements included in each language.

Skill in producing and understanding topic-centered narratives has been shown to be closely related to literacy development and to success in school (Bishop & Edmundson, 1987; Boudreau, 2006; Boudreau & Hedberg, 1999). Children from high-context cultures with little experience of this narrative style may encounter difficulties in the many academic tasks that require processing and producing these narratives. As Westby (2005) pointed out, topic-centered narratives form a bridge between high-context, oral language styles and the low-context, literate language style of the classroom for mainstream as well as for culturally different children. Moreover, Fiestas and Peña (2004) argue that narrative production requires children to manage cognitive load in planning extended discourse, and thus is a good way to assess higher-level cognitive-linguistic skills. They report data indicating that narrative is a valid and relevant task for assessing higher-level language

FIGURE 5-1 Narrative structures across cultures. (Adapted from Westby, C. [November, 1989]. Cultural variations in storytelling. Paper presented at the National Convention of the American Speech-Language-Hearing Association. St. Louis, MO; and Kaplan, R. [1966]. Cultural thought patterns in intercultural education. *Language Learning*, 16, 1-2.)

skills in bilingual children. When assessing narrative development in clients, it is important to be aware of the possible problems children from traditional cultures can have with topic-centered narratives. Rojas and Iglesias (2006, 2009) provide guidance on eliciting and scoring narrative samples from Spanish-speaking children, for example. For all children with CLD we want to be careful not to imply that the topic-associated narrative styles with which the client is familiar are wrong. Rather, we will want to encourage students to learn an additional style to be used when telling stories in the classroom or mainstream setting.

Working with Families from Culturally Different Backgrounds

As we'll see when we talk in the following chapters about working with young children, the best practice in child language disorders is *family-centered*. This practice involves helping families to identify concerns, priorities, and resources for their child and including them as integral members of the intervention team (Donahue-Kilburg, 1993; Hidecker et al., 2009; Pedersen & Vining, 2009). Family-centered practice with families whose cultural background differs from our own operates on exactly the same principles. We must respect the concerns and priorities of families whose experiences and values diverge from ours, just as we do those of families whose beliefs are more familiar to us. As both Hwa-Foerlich and Westby (2003) and Peña and Fiestas (2009) pointed out, differences in beliefs and values about learning, parenting, and disabilities can lead to confusion and misunderstanding. Therefore, we need to be aware of how our own assumptions and expectations affect our interactions with CLD families (Kohnert, 2008). Goldstein and Iglesias (2006) and Roseberry-McKibben (2008) suggested the strategies for culturally sensitive family-centered practice that are summarized in Box 5-7. In addition, Cheng, Battle, Murdoch, and Martin (2001); Coleman and McCabe-Smith (2000); Goldstein (2000); Johnston and Wong (2002); Lynch (2004b); and McNeilly and Coleman (2000) discuss issues related to developing cultural competence for working with families of CLD children. Clinicians would benefit from reading and studying these texts to develop culturally sensitive practices.

We'll talk in more detail about family-centered practice in the next few chapters. The important point to remember here is that the principles and communication strategies we'll discuss apply to families that come from diverse cultures as well as to families in the mainstream.

BOX 5-7 Strategies for Developing Culturally Sensitive Family-Centered Practice

- Be sure family members (and in many CLD families, family members other than parents will be involved) understand the purpose of each assessment or intervention session.
- Attempt to involve family members in making decisions about assessment methods and interpretation, intervention targets and procedures, etc.
- Match assessment and intervention goals to family priorities.
- Allow ample time for questions after each session, and be prepared to answer the same question different ways for different family members, if necessary.
- Research the language and culture of each client (using sources like those cited in this chapter) to make use of culturally appropriate practices.
- Team up with people from the cultural community who can act as both language and cultural interpreters.
- Read about the family's culture.
- Visit student homes.
- Consider family value systems when setting goals; for example, independence is highly valued in our culture, even for young children. Families from more traditional cultures may not think young children need to be independent and may reject intervention that aims to increase independence, such as using a remote switch for a young physically handicapped child to turn on the TV himself.
- Invite students to share aspects of their culture with other students.
- Learn some basic communication (simple phrases, common words) in the student's home language.
- Learn to pronounce students' and family members' names as they are pronounced in the home language, not as they are "Americanized."

Based on Goldstein, B., and Iglesias, A. (2006). Issues of cultural and linguistic diversity. In R. Paul and P. Cascella (Eds.), *Introduction to clinical methods in communication disorders* (2nd ed., pp. 261-280). Baltimore: Paul H. Brookes; Roseberry-McKibbin, C. (2008). *Multicultural students with special language needs*. Oceanside, CA: Academic Communication Associates.

ASSESSING CULTURALLY AND LINGUISTICALLY DIFFERENT CHILDREN

Language Disorder or Language Difference?

The first problem in assessing a culturally or linguistically different child is determining whether a real disorder exists or whether there is merely the perception (usually on the part of teachers or other

professionals) of a disorder that is based on a language difference. Laing and Kamhi (2003) point out that over- (and under-) diagnosis of language and literacy problems are common in CLD children. ASHA's *Issues Brief on CLD Students* (2006; Appendix 5-1) reports the incidence of communication disorders in CLD populations should be no higher than in English-only populations (around 10%) and the Individuals with Disabilities Education Act (IDEA) makes provisions for ensuring that over-identification of minority populations is not occurring in the schools. Part of the reason for over-identification is an over-reliance on standardized tests that are often plagued by biases that reduce their validity for assessing these children fairly. Qi (2006) pointed out that children from CLD backgrounds often score lower on standardized tests because they are unfamiliar with test-taking situations or lack experience with the concepts and knowledge contained in the standardized tests.

Taylor (1986) suggested that a language disorder should be diagnosed in a CLD child only when the child's language skills deviate significantly from the norms and expectations of the child's home community. Wilson, Wilson, and Coleman (2000) outlined the criteria for identifying language disorders in CLD clients. A language disorder is likely to exist if the client's communication:

- Is considered defective by the individual's cultural community
- Operates outside the norms of acceptability for that community
- Calls attention to itself or interferes with communication within that community
- Results in difficulties in adjustment for the client

So the initial step in the assessment process for any CLD child is to determine whether language is disordered or simply different. We need to find out whether a problem is perceived because of a difference in cultural expectations for communication or because the child has a genuine disability, even in the home culture. Let's take an example to see how over-identification can happen.

Harry was a Native American child recently arrived from the reservation to an urban Head Start program. He seemed to the teachers to be inordinately quiet. When asked a question, he took an exceedingly long time to answer, causing the teachers to question his comprehension skills. He had a great deal of difficulty presenting information during sharing time and did not seem to process teachers' verbal directions. He was referred for speech and language assessment. Ms. Lopez, the SLP, observed his classroom behavior and saw the same problems that the teachers had indicated.

Before deciding Harry had a disorder, however, she interviewed Harry's parents. She found that they spoke both English and Navajo in the home. Both were fluent in English and had jobs in which they conversed with English speakers regularly. They believed that Harry was proficient in English; he watched English-language TV and played with English-speaking children after school and seemed to get along with them alright. They didn't really understand why he should be having so much trouble in school.

Ms. Lopez decided to collect a language sample from Harry during a play period with a peer. She analyzed the sample and found that Harry's use of syntax and semantics was generally age-appropriate. Receptive language testing, using a standardized picture-pointing test, showed that Harry's receptive vocabulary score was somewhat below the normal range. Ms. Lopez asked

the parents about the items Harry failed to identify on the test, and they explained that he was unlikely to have encountered those words in their home or on the reservation. Ms. Lopez assessed Harry's comprehension of classroom directions with some criterion-referenced measures. She found that Harry could follow most directions, but was very slow and careful about doing so. When she asked his parents why this might be the case, they explained that he had been taught at home to think carefully before acting. They commented that Harry had once said that the teachers seemed to want him to act like a "show off" in school.

Ms. Lopez concluded that there was a mismatch between the teachers' expectations and Harry's communication style. While Harry would need some help in developing some of the vocabulary items with which he'd had no previous experience, consulting with teachers about some concepts to emphasize in the course of their regular program could do this. Ms. Lopez also shared her nonstandardized assessment results with the teachers and talked with them about Harry's need to consider before answering and his unwillingness to stand out from the group in sharing time. She suggested some ways they could modify their interactions with Harry that could bring their communicative expectations more in line with his. She also suggested that they talk with him about some of the different ways people can be expected to act at school and at home, so that some of the school rules might seem less foreign to him.

In Harry's case, the assessment suggests a difference rather than a disorder of communication. The remedy for this situation is two-pronged. Some work must be done to help Harry adjust to the communicative demands of the classroom. This work, however, should be culturally sensitive; care should be taken not to invalidate the styles of communicating that are appropriate at home. The second prong consists of making some adjustments in the classroom's communication requirements. This would include consultation with teachers to make them aware of Harry's communication style, assuring them that it is a difference rather than a disorder and that Harry has the potential to communicate effectively. It also would involve finding ways to accommodate his communication in the classroom setting.

Recently, at least one assessment method has been developed to address this issue directly in children who speak AAE. *The Diagnostic Evaluation of Language Variation* (DELV) (Seymour, Roeper, & deVilliers, 2005) was developed as a valid and reliable assessment that allows the clinician to identify AAE speakers with language impairments regardless of the dialect of the child. The DELV is available in both screening and full diagnostic forms, and also provides items that identify speech delays in AAE speakers. Based on extensive research of both typical and delayed development in AAE (Bland-Stewart & Pearson, 2006; Pearson, 2004), the DELV provides clinicians with at least one psychometrically sound tool for diagnosing language disorders in AAE speakers. Thomas-Tate et al (2006) also report data suggesting the *Expressive Vocabulary Test* (Williams, 2006) is another valid assessment for AAE speakers, although Champion (2010) and Washington and Craig (1999) question whether its companion measure, the *Peabody Picture Vocabulary Test* (Dunn & Dunn, 2007) is equally valid. We'll talk in the following sections about some additional issues in using standardized tests to help determine whether a

language difference or disorder is present in clients from various CLD backgrounds.

Another approach is suggested by Laing and Kamhi (2003). They report on the use of processing-dependent tasks, which require minimal use of prior knowledge or experience. Examples of processing-dependent tasks include various memory tasks, such as digit span (repeating a series of numbers in random order), working memory (children hear a sentence, are asked to tell whether it is true, and then recall the last word in the sentence), and non-word repetition (repeating nonsense words varying in length from two to four syllables that have no resemblance to familiar English words). These tasks are thought to be less biased because they do not depend on knowledge of culturally determined information, such as vocabulary (which children learn from hearing their parents talk). Instead they tap directly the processes that go into learning language. Laing and Kamhi (2003), Hwa-Froelich and Matsuo (2005), and Weismer et al. (2000) reported that, when children perform poorly on processing-dependent measures, there is a high likelihood that they will have some type of language-learning difficulty. The use of processing-dependent measures with CLD populations makes sense because they are not biased regarding life experience, socialization practices, or literacy knowledge, and they are quick and easy to administer. Moreover, many non-word repetition and working memory measures are included in currently existing standardized measures, including the *Comprehensive Test of Phonological Processing*, or in clinical literature, such as the *Non-word Repetition Test* (Campbell, Dollaghan, Needleman, & Janosky, 1997), as just two examples.

A third approach to this question is the use of dynamic assessment procedures. We talked about dynamic assessment in Chapter 2. From there, you will remember that one approach to dynamic assessment is to test, teach, and then retest. This method of dynamic assessment has been shown to differentiate stronger and weaker language learners in Puerto Rican, African-American, and Native American preschool and kindergarten children (Laing & Kamhi, 2003; Ukrainetz, Harpell, Walsh, & Coyle, 2000). Another method of dynamic assessment was examined by Peña, Iglesias, and Lidz (2001). They used Mediated Learning Experiences (MLE), designed to teach children principles or strategies for learning a task, to determine whether these supports would distinguish language difference from language disorder in preschool African-Americans and Latino American children with low levels of language performance. All children received pretest standard language measures. Children were then taught new vocabulary items; some received MLEs organized around theme-based play and book-sharing activities, others received no mediation. All were post-tested on the same tests. Findings revealed that changes in the post-test scores on knowledge of the new vocabulary were associated more closely with the presence of mediation than with pretest standard scores. Miller, Gilliam, and Peña (2001) reported similar findings for a dynamic narrative assessment task.

Dynamic assessment also allows us to learn, for those children who do not improve in quantitative test scores after an intervention, whether their responses are qualitatively improved; for example, whether they provide longer responses, or responses closer to the target than they did before. These changes, too, are indicative of a benefit from the intervention and can be used to help distinguish a language difference from a disorder. Gutierrez-Clellen and Peña (2001) provide information on various dynamic assessment techniques, which are summarized in Table 5-3. ASHA's multimedia tutorial on the use of dynamic assessments with CLD students

is another useful resource that can be found at www.asha.org/practice/multicultural/issues/Dynamic-Assessment.htm.

Finally, Lewis et al. (2010) propose an approach that they call "Assessment 360" for ELLs. They recommend a comprehensive approach that takes advantage of a range of assessment methods. This approach is summarized in Table 5-4. Craig and Washington (2006) also propose a model of assessment specifically adapted for AAE speakers.

Establishing Language Dominance

As a first step toward determining whether there is a language difference or disorder, we need to identify the child's dominant language. That is, we need to determine whether the child's primary language is English or some other language. The reason that establishing language dominance is important concerns our responsibility to do least-biased assessment. The Individuals with Disabilities Education Act (Part B)—the federal law that guarantees a free, appropriate public education in the least restrictive setting to every child regardless of handicapping condition—requires that testing be provided in the language or other mode of communication in which a child is most proficient. If we test an ELL child in English, of course, all we will find out is that he or she has limited English skills. We won't know whether the child really has a language disorder or simply hasn't yet had the opportunity to develop fluency in English. IDEA regulations issued in 2006 emphasize that evaluation of CLD students does not necessarily need to include standardized testing, but must take place "in the form most likely to yield accurate information on what the child knows and can do academically, developmentally, and functionally." While this does not necessarily mean that assessment *must* be administered in the home language, it does mean that we need know whether the home language or English is the child's stronger communication modality in order to decide which will yield the most valid information.

Kayser (1995) provided some suggestions for establishing language dominance in CLD children. Observation is one method. Here the clinician would observe the child in the classroom and in less formal settings, such as the lunchroom or playground, and chart communicative behaviors in each. Heavy reliance on gestures in situations requiring English or a preponderance of the home language in informal situations would suggest that English is not dominant for this child. A second method is the use of structured questionnaires to assess language dominance. Some examples include the *Assessment Instrument for Multicultural Clients* (Adler, 1991), the *Basic Inventory of Natural Language* (Herbert, 1977), the *Bilingual Language Proficiency Questionnaire* (Mattes & Santiago, 1985), the *Bilingual Syntax Measure* (Burt, Dulay, & Hernandez-Chavez, 1975), the *Home Bilingual Usage Estimate* (ASHA, 1982a), the *Oral Language Evaluation* (Silvaroli & Maynes, 1975), the *PAL Oral Language Dominance Measure* (Apodaca, 1987), and the *Teacher Language Observation Report* (ASHA, 1982b).

If English is found to be the dominant language, testing in English can proceed. With a CLD child, however, testing in English requires sensitivity to pragmatic, experiential, and dialectal differences that must be evaluated before deciding whether a disorder is present. As we saw in Harry's case, a child can be English-dominant and still have a culturally different communication style. As discussed in Chapter 2, standardized tests do not provide all the information we need to answer these questions in a CLD child, just as they do not for any other child. Particularly for the CLD child, however, standardized measures should be

TABLE 5-3 Dynamic Methods for the Assessment of CLD Children

Method	Description	Purpose	Example
Test the limits	Traditional test procedures are modified by providing feedback about the correctness of the answer, why it was correct or incorrect, and an explanation of the principle in the task; or by asking the child to describe the test question and tell why they gave the answer they did.	To get a more accurate assessment of the child's knowledge of items on the test; modified responses cannot be included in standard scoring, but supply deeper information about the child's knowledge.	When child is incorrect on expressive vocabulary test, point to the stimulus and say, "Yes, we do eat that. Do you know a special name for this thing?"
Interview on responses	Generate questions to help children understand how they are thinking about test problems and help them become aware of targets skills.	To understand how the task appears from the child's point of view.	When child is incorrect on expressive vocabulary test, ask questions such as, "How did you know that?" or "What would happen if you wanted one of these from the store? What would you say?"
Graduated prompting	Identify Zone of Proximal Development (ZPD) by providing a hierarchy of prompts to vary the level of contextual support.	Child responses to the prompts are used to make predictions about response to intervention. Number of prompts needed to elicit targets can predict gains after intervention.	To predict readiness for productions of 2-words utterances, provide a hierarchy of prompts for single words; such as: modeling (It's a baby), modeling with elicitation (It's a baby; what is it?), and modeling with obstacle (withhold object until child says word). Fewer cues needed for word production predicts readiness for multiword speech.
Test-teach-retest	Identify deficient or emerging skill; provide intervention by teaching principles of the task; post-test to find out how modifiable the child's performance is.	To equalize students' experiences that can affect test performance.	If a child performs poorly on a language test, provide instruction on items similar to those in the test by giving verbal explanation, models, examples, and prompts. Post-test on an alternate form.
Measure modifiability	Likert scales developed by the clinician used to rate the child at the beginning and end the intervention phase of dynamic assessment.	To document change in child behaviors not measured by pre- or post-tests.	Amount of support provided. 1 2 3 Maximal Minimal Child responsiveness to tasks: 1 2 3 Maximal Minimal

Adapted from Gutierrez-Clellen, V., & Peña, E. (2001). Dynamic assessment of diverse children: A tutorial. *Language, Speech, and Hearing Services in School*, 32, 212-224.

supplemented with criterion-referenced and other nonstandardized information to obtain a full picture of the child's communication skills.

If English is not the CLD child's dominant language, Kayser (1995) suggested testing further in both English and the dominant language. Naturally, scores in English will be lower than those in the dominant language, but comparing performance in the two gives the clinician an idea of whether the child is progressing adequately for age in the home language and where gaps in English proficiency are found. Owens (2009) suggested testing in the dominant language first, then following up with testing in English. As Appendix 5-2 shows, there are a variety of tests available in a range of languages for children with CLD. If the clinician has a child who is dominant in one of these languages on the caseload, testing may be carried out by a trained native speaking paraprofessional or speech assistant who can report results to the SLP for interpretation.

Is there always a dominant language or dialect? Davison (2009) discussed the typologies of bilingualism. She pointed out that speakers can have varying degrees of competence across each language and varying durations of exposure to each. Her system for classifying this variety in individuals learning two languages appears in Table 5-5. As it shows, it is not always the case that one language dominates over another.

Obtaining Interview Data

Just as we need to gather data on hearing, speech-motor, and non-verbal skills for every client suspected of a language disorder, we need to gather these data on children with CLD, obtaining information about a child's medical, language, feeding, and developmental and language history regarding both the child and other family members (Pruitt et al., 2010); interviewing parents about current skills in communication and related areas; and finding out about

TABLE 5-4 A Model for Comprehensive Assessment of English Language Learners

Type of Assessment	Information Provided	Source
Developmental history	History of language acquisition Age of first word, word combination Like/unlike siblings Like other children in the community Medical history that could affect speech and language development Hospitalizations Ear infections PE tubes Feeding problems	Parents
School history	History of schooling U.S./non-U.S. academic settings Stable or interrupted Instruction in English or home language History of supports for 2nd language acquisition Supportive/non-supportive environment Academic progress similar/not similar to ELL peers	Parents, teachers, school records
Language use history	Use of primary and secondary language at home with parents, siblings, extended family, and friends Language preferences in different settings or for different activities	Parents, student
Dynamic assessment	Ability of child to learn new tasks in structured teaching environment Assists in differentiating a child who has not had the opportunity to learn a language skill from one who has difficulty learning new skills	Test, teach, test procedure with student
Language sampling	Child's connected speech in less structured, social/interactive tasks, including: Mean length of utterance Narrative structure Pragmatic language skills	Story telling or retelling Conversation
Behavioral observation	Connected speech in social (low structure) vs. academic settings (high structure) to compare BICS vs. CALP Pragmatic language patterns Language preferences	Classroom conversations and cooperative learning with peers
Norm referenced assessment	Quantitative comparison of the child's language skills to typically developing peers	Individually administered tests

Adapted from Lewis, N., Castilleja, N., Moore, B. J., & Rodriguez, B. (2010). Assessment 360: A panoramic framework for assessing English language learners. *Perspectives on Communication Disorders and Sciences in Culturally and Linguistically Diverse Populations*, 17(2), 37-56.

family concerns and priorities are important parts of the assessment for each child we see. For the CLD child, however, these tasks become more complicated, because the SLP and the client's parents may not speak the same language. One solution to this problem is to employ interpreters.

Bilingual individuals can often interpret between clinicians and parents, giving the clinician access to crucial information about clients. Not everyone who is bilingual can be an interpreter, though. Interpreting for clinical purposes requires special skills. Kayser (1991) suggested that interpreters need to have at least a high school education, an ability to relate to people with disabilities, and strong linguistic and literacy skills in both languages. They should be able to say things in different ways and retain chunks of information while interpreting. Lynch and Hanson (2004b) point out that the interpreter needs to be able not only to translate from one language to another, but also to interpret cultural cues and convey the nonverbal aspects of the message as well as its words. Interpreters also need to have good command of medical and educational vocabulary and be able to rephrase

terms for parents. They must be trained to maintain confidentiality and neutrality. Langdon (2002) advocates following a three-step process that includes briefing, interaction, and debriefing (BID) in preparing interpreters for a session. This process is summarized in Box 5-8. Derr (2003) emphasized that, for these reasons, it is usually better for the interpreter not to be a member of the client's family or close personal friend. The American Speech-Language and Hearing Association (ASHA, 1988) recommended using professional interpreters from language banks, bilingual professional staff from other disciplines, or bilingual teachers' aides or paraprofessionals as interpreters. ASHA guidelines for working with interpreters can be found at: www.asha.org/practice/multicultural/issues/interpret.htm. Langdon (2002) and Langdon and Chen (2002) also provided detailed guidance for SLPs on working with interpreters.

Interpreters function essentially as paraprofessionals under the direction of the SLP, with the clinician maintaining responsibility for decisions in assessment and intervention. It is important, however, that they understand the rationale and procedures being used

TABLE 5-5 Davison's (2009) Typology of Bilingualism

Type	Description	Example
Additive	A second language is learned without any adverse effect on the first language.	A child comes to the New York from Puerto Rico at age 4; her first language is Spanish. She goes to preschool and acquires English, but continues to speak Spanish at home, to read books in Spanish her parents provide, and to visit grandparents in Puerto Rico each summer, where she attends summer enrichment programs in Spanish.
Subtractive	A second language is acquired, but the first declines.	A child of American parents who have been living in France since his birth moves back to the U.S. at age 6. The child goes to school and learns to read in English. French is no longer used at home regularly, and no French reading material is available. In high school the child takes French, but has only a moderate advantage over other students.
Dominant	An individual speaks two languages, but has a higher degree of proficiency in one language than the other.	An adult takes a job in northern Mexico, but lives in Texas. He has studied Spanish in school, and takes additional classes. He learns to converse with his co-workers in Spanish, and to understand what is needed for the job, but he continues to speak English outside of work. He has difficulty with conversation in Spanish about non-work related topics and does not read in Spanish.
Balanced	An individual has equivalent competence in two languages.	A child comes to the U.S. with her family from Sudan at age 3. She is fluent in Arabic. She attends preschool and school in English, but attends a community after-school program through high school, where she learns to read, studies religious texts, and continues to converse in Arabic.
Simultaneous	A child is exposed to two languages from birth.	A child is born to a Russian speaking mother and English speaking father. Mother speaks to the child in Russian, father in English. The child is home with mother until the age of three when he enters preschool. Mother continues to speak Russian to him.
Sequential	A child is exposed to one language from birth; second language acquisition occurs later in child development.	A child is born in China and is exposed to Mandarin from birth. When she is five, her parents move to San Francisco. She enters school and begins learning English.

BOX 5-8 Langdon's (2002) BID Process for Working with Interpreters

Briefing: Clinician and interpreter review client's background information and outline the purpose of the session.

Interaction: Each team member addresses the client or family when speaking, even when through the interpreter ("Are you . . ." rather than, "Ask Ms. X if she . . ."). The clinician must always be present with the interpreter, to monitor task presentation and client/family reactions.

Debriefing: Clinician and interpreter review the session and develop a follow-up plan. Clinician should give interpreter feedback on performance and seek interpreter's impressions of client/family responses.

in the interview and that time is spent with them before the parent conference discussing the information the clinician hopes to obtain. They can be asked to review the clinician's questions for cultural appropriateness and to help find alternative ways to get information that families may be uncomfortable giving. Bernstein (1989) suggested that one way to evaluate whether an interpreter has been trained adequately is to borrow a technique from anthropology. Here two interpreters are used. One translates the clinician's questions into the second language and the other translates the responses into English. In this way the clinician can assess whether the interpreter will correctly convey the sense of the interview to the family.

Westby (1986) suggested that a good interview question to begin with in obtaining history information on CLD clients is, "Is this child like your other children or different in some way?" Interpreters translating parents' answer to such a question should understand and have discussed with the clinician the kinds of differences that will contribute to a decision about a language disorder, so that these can be reliably conveyed to the clinician. ASHA Multicultural Affairs offers a handout on cultural norms that may be useful. It can be found at www.asha.org/uploadedFiles/practice/multicultural/issues/ELL_CulturalNorms.pdf#search=%22cultural%22.

Using Standardized Tests with CLD Children

When assessing CLD children's communication in the dominant language and in English, we have basically the same methods available as discussed in Chapter 2: standardized tests, developmental scales, criterion-referenced procedures, dynamic assessment, and behavioral observation. As we saw in Chapter 2, the primary purpose of standardized tests is to find out whether a child is significantly different from other children in the area assessed by the test. However, there are dangers in using tests standardized for monolingual English speakers with CLD children (Cesar & Kohler, 2007; Paradis, 2005). In recent years, a variety of standardized tests have been developed in languages other than English for just this purpose. Spanish language tests are the most common, although some tests have been normed in other languages, as well, and some standardized tests have been re-normed or provide alternative scoring rubrics for AAE speakers (Cria & Washington, 2006). Langdon

and Wiig (2009) also discuss tests designed to assess both a first and a second language. Appendix 5-2 presents a sample of standardized tests that can be used to assess CLD children. These tests also can be given along with standardized tests that assess English versions of similar areas. Results can then be compared not only to help determine whether the child is progressing normally in the home language (L_1) but also to identify areas of English (L_2) that are less developed than the dominant language. However, as we would when using any standardized test, we need to be cautious about understanding the properties, strengths, and weaknesses of these measures. Restrepo and Silverman (2001), for example, reviewed the psychometric properties of the *Spanish Preschool Language Scale—3*, a widely used instrument. They found that there were problems in the test's norming sample, reliability, and validity data. Similarly, Restrepo et al. (2006) and Thomas-Tate et al. (2006) both reported that for AAE speakers, the *Expressive Vocabulary Test* (Williams, 2006) appears to be a valid assessment, although its companion measure, the *Peabody Picture Vocabulary Test* (Dunn & Dunn, 2007) had a greater tendency toward false positive identification. These findings suggest that we need to carefully review the manuals for any test we select for use with our clients, and attempt to find those that meet high psychometric standards for inclusive norming samples, validity, and accuracy (Stockman, 2010).

Brice (2002), Goldstein (2000), Kayser (1995), Langdon and Wiig (2009), Roseberry-McKibben (2002a), and Wyatt (2002) have made suggestions for modifying standardized tests to gain information about language proficiency in CLD children. They suggest that adapting tests should be a group effort, since a monolingual SLP

making the modifications in isolation might not make adaptations that are optimal for speakers of a different language. The SLP can enlist bilingual ESL teachers, psychologists, special educators, and community members to make the modifications. Suggestions for adaptations of tests are given in Box 5-9. Adler (1993) and van Keulen, Weddington, and DeBose (1998) also presented some modifications of standardized tests that can be applied when testing speakers of nonstandard dialects.

Oetting et al. (2008) presented an additional approach. They suggest using cut-off scores for standard tests that are derived empirically (that is, selected based on their ability to differentiate children with known diagnoses from those with typical development) and combining these with process measures like non-word repetition provides a high degree of accuracy in identifying CLD children with language disorders. Guitierrez-Clellan et al. (2006) developed a measure to assess Spanish morphosyntax as a way of identifying Latino preschool children with language disorders. This approach represents another way to develop an accurate classification scheme, and can be applied to additional languages by SLPs with expertise in languages other than Spanish.

For many CLD children, however, standardized tests of the home language will not be available. In this situation we have some alternatives. An obvious alternative is to have an interpreter translate a standardized test into the child's home language. Cheng (2002a); Goldstein (2000); Langdon and Wiig (2009); and Wilson, Wilson, and Coleman (2000), however, cautioned against this practice. Words and concepts common in mainstream culture may be unfamiliar to the CLD child, so failure to use or recognize them in the home language would not necessarily indicate a deficit. Translating

BOX 5-9 Suggestions for Modifying Standardized Tests for Assessment of CLD Children

1. Review test content for items that tap knowledge or experiences CLD children are unlikely to have. Determine whether modification can reduce bias.
2. Have members of the team perform the tasks on the test and make suggestions about how to make them less culturally biased.
3. Consider administering the test to an adult from the community to get information on the appropriateness of the test items.
4. Review past testing of CLD children to look for items or subtests that were problematic for many of these children.
5. Make an effort to identify tests that include substantial numbers of individuals from CLD backgrounds in the norming sample.
6. Determine appropriateness of vocabulary for community; poll team for most appropriate vocabulary to use for local children.
7. Review pictures for familiarity. Substitute other pictures or objects for those likely to be unfamiliar.
8. Reword instructions to make them more comprehensible for CLD children.
9. Give additional practice items to teach children how to take the test.
10. Provide additional response time; repeat items and instructions if needed.
11. Continue testing beyond ceiling.
12. Record children's comments, explanations, and changes of response for qualitative analysis.
13. Observe *code switching* (alternations between languages within an utterance) and *language interference* (the influence of one language on another, such as mispronunciations due to accent), and interpret how these affect performance and results.
14. Compare children's answers not only to the "right" answer according to test norms, but also to dialect, home language, or second-language learning features. Rescore articulation and expressive language results, giving credit for these kinds of variations.
15. On picture-pointing tests, have children name the items as well as point to those named by the tester, to examine the appropriateness of the children's label.
16. Have children explain why they answered as they did, if answer is incorrect according to test norms.
17. Report all modifications when writing up assessment information; use norm-referenced scores with caution, and only if they are valid for the population to which the client belongs.

(pp. 261-280) Baltimore: Paul H. Brookes; Erickson, J., & Iglesias, A. (1986). Assessment of communication disorders in non-English-proficient children. In O. Taylor (Ed.), *Nature of communication disorders in culturally and linguistically diverse populations*. San Diego, CA: College-Hill Press; Kayser, H. (1995). Speech and language assessment of Spanish-English speaking children. *Language, Speech, and Hearing Services in Schools*, 20, 226-244; Wyatt, T. (2002). Assessing the communicative abilities of clients from diverse cultural and language backgrounds. In D.E. Battle (Ed.), *Communications disorders in multicultural populations* (pp. 415-459). Stoneham, MA: Andover Medical Publishers; Weddington, G. (1987). Guidelines for use of standardized test with minority children. In L. Cole & V. Deal (Eds.), *Communication disorders in multicultural populations* (pp. 21-22). Rockville, MD: American Speech-Language-Hearing Association.

also invalidates the standardization of the test, defeating the purpose of using it in the first place. Goldstein (2000), Langdon and Wiig (2009), and Kayser (1995) suggested that it is wiser to modify or adapt test items than to translate them directly. When these modifications are made, of course, the adapted instrument is no longer a standardized test. We are, in effect, using the standardized test as a criterion-referenced measure. Although this method will not tell us if a child is significantly different from other children, it can tell us what forms and functions a child uses and understands in the language being tested.

Wyatt (2002) cautioned that when we do adapt standardized tests for use with CLD children, we need to be especially careful to note the adaptations in clinical reports on the client. She recommended that any changes made in standardized administration or scoring procedures be fully documented in the report. The report also should state whether an interpreter was used and how the interpreter was trained to administer and score the test. When testing takes place in two languages, the languages used and the order of use of the languages (English first, Spanish second, for example) should be given. Norm-referenced scores should be reported only when they are appropriate for the way the test was administered. If the test was adapted in any way, norm-referenced scores cannot be used without reservations. If published developmental data are used for comparison to the child's performance, full bibliographical reference to the published data should be made.

Another alternative for assessing a CLD child's language proficiency is to develop local norms for standardized tests (Goldstein & Iglesias, 2006). This option only makes sense when a large number of CLD children from similar backgrounds reside in an SLP's district. Kayser (1995) warned that developing local norms is not as easy as it sounds. Groups of CLD individuals are heterogeneous in terms of socioeconomic status, length of time in this country, and degree of acculturation. All these differences can affect their performance on a test. Adler (1990) suggested that developing local norms may not really help identify CLD children with genuine language disorders, because the "culture fair" data represented in the local norms may not be relevant to the realities of classroom expectations. Harris (1993) advised that if local norms are to be developed, they should have at least 50 individuals at each age or grade level who are randomly selected from the community to provide the norms. Both means and standard deviations should be computed. Children falling 1, 1.5, or 2 standard deviations below the mean for their community group might be identified as language disordered, depending on the criterion for language disorder being used by the clinician. However, Carter et al. (2005) remind us that these local norms should show a normal distribution, or bell-shaped curve. If they do not, the assessment should be modified so that a normal distribution is achieved. Bayles and Harris (1982) found that using local norms in this way decreased the percentage of children from CLD families identified as having language impairments.

Whether we adapt tests or develop local norms, several guidelines should be followed. These are outlined by Carter et al. (2005) and include the following:

- Include native speakers of the home language in the development of the instrument, including paraprofessionals, teachers from the community, and other local informants.
- Pilot-test the assessment on a representative sample of typically developing children from the home community.
- Pilot-test pictures to be used in the assessment by asking young, typically developing children from the community to

identify them. Any pictures not recognized by the pilot sample should be redrawn or discarded.

- Pilot-test instructions, practice items, etc., as well before using the test to identify deficits in the home language.
- Whenever possible, have the assessment administered by native speakers of the home language.
- Use materials familiar to children from this community; for example, types of trees and flowers in pictures should be those with which the children will be familiar.
- For children who are unfamiliar with the testing situation, consider giving extra practice items.

Terrell, Arensberg, and Rosa (1992) suggested an additional alternative use for standardized tests with CLD children: Parent-Child Comparative Analysis (PCCA). This is a method of assessing children who come from cultural groups too small for development of local norms. Here an identical battery of tests is given to both parent and child. The child's performance is compared not to test norms but to the parent's responses. Any patterns that match patterns produced by the parent are considered dialectical variations rather than errors. If the child's patterns do not match the parent's, the child's responses are compared to age expectations, using developmental charts and normal language data, such as those found in Haynes and Shulman (1998b) or Owens (2008). Deviations from Standard English patterns that do not match the parent's and are not typical of normally developing children of the client's age are considered aspects of a language disorder.

Developmental scales that look at nonlinguistic areas can be a useful adjunct to assessment of the CLD child. As discussed in Chapter 2, developmental scales and collateral, nonverbal assessments can provide information about motor, self-help, nonverbal cognitive, problem-solving, and play skills that can help to identify gaps between linguistic and nonlinguistic development in CLD children, as they can in clients from mainstream backgrounds. Many of the instruments we talked about in Chapter 2, particularly those that are nonverbal or minimally verbal in format, are appropriate for rounding out our picture of the skills of the CLD child. Ortiz (2001) also suggests determining the degree of "cultural loading" on these assessments; that is, the degree to which a test requires specific knowledge and experience with mainstream culture. His article provides a list of tests of cognitive and collateral areas classified by their degree of cultural loading.

Criterion-Referenced Assessment of CLD Children

IDEA 2006 specifically permits the use of nonstandard assessments for CLD children if they are most appropriate for the evaluation of a student. Criterion-referenced assessment is used with CLD children in much the same way as for a mainstream child (that is, we use criterion-referenced measures once standardized testing has established that the child is significantly different from peers—in the CLD child's case, peers from the home culture—in linguistic development). The criterion-referenced assessments are then used to establish baseline function, identify goals for intervention, and document progress in the remedial program. Interpreters can be especially helpful in carrying out criterion-referenced assessments. When testing a child who is not English dominant, we may want to assess forms of interest in both the first language and English, to identify gaps between the two as well as establish level of functioning in the dominant language.

Since standardization is not an issue for criterion-referenced assessments, many of the criterion-referenced procedures in the following chapters can be translated directly by an interpreter into a CLD child's first language. The only thing we will need to be careful about is that the forms and procedures used in the assessment are culturally appropriate. For example, if a child's home culture's communication style dictates that you don't tell people something they already know, asking a child to tell what color a picture is may be inappropriate, even if the question is asked in the native language. Perhaps the situation would have to be modified so that the question concerns a picture that the examiner cannot see, to make the question pragmatically appropriate for the CLD client. Here, too, consulting ahead of time with the interpreter about culturally appropriate procedures can help prevent problems.

We talked in Chapter 2 about the importance of structural analysis of spontaneous speech samples as one aspect of criterion-referenced assessment and about some guidelines for collecting speech samples that truly represent a child's productive language skills, and Horton-Ikard (2010) discusses the use of language samples for assessment purposes in CLD population. When language sample analysis is part of the assessment of communication in the CLD child, certain cautions need to be kept in mind. Stockman (1996) points out a central concern to us: language sampling is not used to identify a disorder in mainstream children. Instead, it is used when a disorder has been identified with standardized testing and we want to investigate baseline function and target expressive language goals for intervention. Because language sampling procedures do not meet psychometric standards of reliability, validity, sensitivity, and specificity, they cannot properly be used to decide that a child is significantly different from other children. We can use language sampling with CLD children just as we use it for children from mainstream backgrounds: to describe current functioning in the dominant language and in English, to identify goals for intervention by establishing the next steps in the normal sequence of acquisition of either language, and to target these goals in an intervention program. Rojas & Iglesias (2010) illustrate how SLPs can use language sampling with ELLs to track progress. Information in Price et al. (2010) using computerized language sample analysis is relevant for CLD students as it is for others. The SALT computer program (Miller and Iglesias, 2008) has measures specifically designed for Spanish speakers.

When collecting a language sample for these purposes from a CLD child, it is important to remember that conversational rules are culturally determined. To get a valid sample of a CLD child's language, then, we need to attend to the cultural rules that govern conversation for that child. Perhaps children are not expected to speak extensively to adults in a certain culture. In this case, a more valid sample might be collected from a peer interaction. Leonard and Weiss (1983) emphasized the importance of incorporating culturally appropriate materials and topics into the evaluation. These all help to obtain a more representative picture of the child's linguistic skills. To monitor the representativeness of a speech sample collected from a CLD child, we will want to learn some details of the cultural conversational practices from interviews with community members. In addition, we may want to observe the client in several conversational situations to select the most representative one to use as the basis for our speech sample analysis. It also is a good idea to check with a parent or familiar adult to ask whether the sample we plan to analyze sounds like the way the child usually talks. Narrative samples can be of use for the same types of clients with CLD who function at school-age levels.

Kit-Sum To et al. (2010) and Rojas and Iglesias (2009) provide guidance for collecting narrative samples from children with Spanish and Cantonese backgrounds.

Language samples can be collected in the home language from children who are not English dominant. In this case, the child may interact with a parent or another fluent speaker of the language. The sample can be audio recorded and transcribed by an interpreter. Again, the interpreter will need to be carefully trained by the clinician so that the transcription accurately represents the child's pronunciation, use of grammatical morphemes, word order, and any other aspects of speech that the clinician wants to examine. Without training, the interpreter may be tempted to "normalize" the child's speech, correcting the child's errors in the transcription and removing an important source of information about the child's linguistic patterns. A translation of the sample will need to retain some indication of these errors to be analyzed by the clinician in collaboration with the interpreter.

The language sample from the home language will be especially useful for determining whether the child is learning normally in the first language. Norms for Spanish acquisition are available (see Fabiano-Smith & Goldstein, 2010; Haynes & Shulman, 1998b; Uccelli & Paez, 2007), and a Spanish-speaking child's spontaneous speech can be compared with these normative data. Goldstein (2001) and Linares (1981) provided rules for computing mean length of utterance in morphemes in Spanish. For languages for which normative data are not available, the interpreter and the clinician can consult with the parent and other bilingual individuals in the community.

Collecting a sample of the child's speech in English also can be helpful. Here we would compare the child's errors in English to those made in the home language to look for similar difficulties in the two languages. The child might be substituting a /t/ for an /s/ in both languages, for example, or leaving plural morphemes out of both, even where they are required in the home language. These kinds of similarities could indicate that the child is having trouble acquiring language in general, not just in using English. Second, this comparison can identify structures that the child uses correctly in the home language but makes errors on in English. These errors can be examined to determine whether they arise from interference from the home language. If so, they are likely to resolve on their own as the child develops English proficiency, if no other language disorders are present.

Stockman (1996, 2008) has made an additional suggestion for the use of spontaneous speech data as a way to establish whether, in fact, a child is demonstrating a language difference or disorder. The Minimal Competence Core (MCC) is a criterion-referenced measure that represents the least amount of linguistic knowledge needed to be judged normal at a given age within a speech community. Although most speakers will know more than this core, the MCC is designed to identify the linguistic features that the least competent normal child could demonstrate. Because this core includes common obligatory features, it is less affected by contextual and vocabulary differences among situations and speakers. The use of this metric requires, of course, a detailed and well-researched set of MCC features for each age and dialect. Stockman (1996, 2008) has presented one such set for 3-year-old speakers of AAE. This is presented in Table 5-6.

Craig and Washington (1995) looked at the production of complex sentence types (those containing more than one main verb) in the speech of a representative sample of low income African-American boys aged 4 to 5.5 years old who were living in the urban Midwest. Like Stockman, they found that complex sentence

TABLE 5-6 Minimal Competence Core Features for 3-Year-Old AAE Speakers
Language sampling context: Two-hour speech sample gathered while subject played with race track and cars, then looked at pictures in books.
Productivity criteria: Four correct productions observed anywhere in the 2-hour sample.

Language Domain	Core Features
Phonological	Correct production of the following word-initial consonants by over 90% of participants: /m/, /n/, /w/, /j/, /p/, /b/, /t/, /d/, /k/, /g/, /f/, /s/, /h/, /l/
Pragmatic functions	Comment on objects by labeling or describing Regulate interaction by requesting information or requesting objects or actions Initiate conversational repairs with general query ("Huh?") or spontaneously repeating or revising utterances
Semantic relations	Respond to speech by answering questions, acknowledging or imitating prior utterances Existence State Locative state Action Locative action Specification Possession Time Negation
Morphosyntax	Simple sentences with two to three constituents (subject-verb: I eat; subject-verb-object: I eat candy.) Simple, elaborated two to three constituent sentences with lexical or inflectional modifiers (He eats; I am eating the candy.) MLU 2.7 Use of two or more different grammatical morphemes 3%–10% complex sentences in sample

Adapted from Stockman, I. (1996). The promises and pitfalls of language sample analysis as an assessment tool for linguistic minority children. *Language, Speech, and Hearing Services in Schools*, 27, 355–372; Stockman, I. (2008). Toward validation of a minimal competence phonetic core for African American Children. *Journal of Speech, Language, and Hearing Research*, 51, 1244–1262.

production of at least 3% of a speech sample represented typical performance. They suggest that the appearance of complex sentences within spontaneous speech samples of AAE speakers as they enter school can serve as a screening criterion for determining presence of language disorder within this population. Craig and Washington (2000) explored this idea further and showed that a combination of MLU, percent of complex sentences, and number of different words derived from free speech samples provided a sensitive and culturally fair method of identifying expressive language impairment in school-aged AAE speakers. When combined with receptive measures of responses to *wh*- questions and passive sentences, sensitivity and specificity of this informal measure were excellent for identifying language impairments in this population. Furthermore, Craig and Washington (2004b) show that adding a measure of non-word repetition (imitating nonsense syllables) and a measure of nonverbal cognition to this battery produced a valid, relatively unbiased screening for language impairment in young African-American children. Craig, Washington, & Thompson (2006) extended this study to AAE speakers in elementary grades. Their research used a task involving description of three action pictures (Numbers 5, 7, and 24) from the *Bracken Concept Development Program* (Bracken, 1986). Data they reported, which can serve as a comparison to data collected from AAE clients suspected of language disorder, appears in Table 5-7. Horton-Ikard (2010) pointed out that the measures used by Craig et al. (2006) are relatively unaffected by dialect usage, so using a language sample like theirs can provide a relatively unbiased assessment of language function in AAE speakers.

Leonard and Weiss (1983) suggested another approach. They advocated looking for features with surface realizations that differ

TABLE 5-7 Normal range (± 1 SD from Mean) for Mean Length of Utterance (MLU), Proportion of Complex Sentences (% Comp) and Average Number of Different Words per Utterance (NDW) Produced by AAE Speakers in Grades 1–5 Describing Pictures from Bracken (1986)

Grade	MLU	% Comp	NDW
1	4.8–7.2	21–69	2.4–3.6
2	5.0–7.8	27–77	2.5–3.9
3	5.5–8.5	36–90	2.67–4.1
4	5.9–8.7	61–97	2.7–4.3
5	6.0–9.8	50–99	3.0–4.6

from those expected in Standard American English. For example, several features of SAE are not obligatory in AAE. If a child who speaks AAE omits a plural marker, we will not be able to tell whether the omission represents an error or a rule-governed feature of AAE. Instead, we can look for features that are not omitted but are realized differently in AAE (or whatever the child's linguistic variation is) than in SAE. Horton-Ikard and Weismer (2005) and

BOX 5-10 Features Realized in AAE but Not in SAEDistributive *be*:

AAE: "I be good."

SAE: "I am good sometimes."

Habitual *be*:

AAE: "She be at work on Fridays."

SAE: "She works on Fridays."

Remote time *been*:

AAE: "I been walked."

SAE: "I already walked."

Complete aspect *done*:

AAE: "I done went fishing."

SAE: "I already went fishing."

Inflectional marking after consonant cluster reduction:

AAE: *desse*s, *te*ssingSAE: *desks*, *test*ingEmbedded *do* inversion:

AAE: "He wants to know did she get here."

SAE: "He wants to know if she got there."

Preposed negative auxiliary:

AAE: "Couldn't nobody do it."

SAE: "Nobody could do it."

Existential *it*:

AAE: "It's a new kid in the building."

SAE: "There's a new kid in the building."

Pronoun apposition:

AAE: "My mother she did it."

SAE: "My mother did it."

Adapted from Horton-Ikard, R., & Weismer, S. E. (2005). Distinguishing African American English from developmental errors in the language production of toddlers. *Applied Psycholinguistics*, 26(04), 597; Leonard, L., & Weiss, A. (1983). Application of nonstandardized assessment procedures to diverse linguistic populations. *Topics in Language Disorders*, 3, 35-45.

Leonard and Weiss (1983) provided some examples for AAE, which are listed in Box 5-10. Coles-White (2004) added a related suggestion. She found that typically developing African-American children were similar to Caucasian peers in understanding various negative forms, even when their production of these forms was influenced by AAE. She suggests that testing understanding of forms like the one in Figure 5-2 will be helpful in distinguishing children with dialect usage from those with language disorders.

Another approach to analyzing language samples from children who speak AAE dialect was proposed by Nelson (2010). She presented a modification of the criteria for the *Developmental Sentence Score* (Lee, 1974), called the *Black English Sentence Scoring* (BESS). This procedure uses a set of criteria based on those developed by Lee (see Chapter 8 for details of these criteria) with changes based on patterns typical of AAE dialect. For example, under the first stage of personal pronoun development, Lee places *I*, *me*, *mine*, *you*, and *yours*. The BESS includes *mine's* in this category, since it is used in AAE. Similarly, in the main verb category, absent copulas would be given an "attempt mark" or a score of zero in Lee's procedure. The BESS awards these constructions 1 point, since they are typical of AAE. Using the BESS to analyze a speech sample from a child known to be an AAE speaker is another way to reduce the bias of our structural analysis of the speech of CLD children. Toronto (1976) developed a similar adaptation of the *Developmental Sentence Score*, the *Developmental Assessment of Spanish Grammar*,

FIGURE 5-2 A true double negative item from the grammatical judgment task. In the item depicted, a man is sitting at a table and preparing to feed one of two hungry babies; the baby with hair or the baby without hair. A correct response to the verbal prompt, "He didn't feed the baby with no hair, which one did he feed?" would be to point to the baby with the hair. (Reprinted with permission from Coles-White, D. [2004]. Negative concord in child African American English: Implications for Specific Language Impairment. *Journal of Speech, Language, and Hearing Research*, 47, 212-222.)

for evaluating the syntactic skills of Spanish-speaking children using spontaneous speech samples. Gutierrez-Clellen, Restrepo, Bedore, Peña, and Anderson (2000) discussed the issues involved in conducting language sample analyses on Spanish transcripts. They advocate using a measure of number of syntactic/morphological errors/T-unit. This measure has been shown to have a cut-off of 10 errors in 50 utterances for identifying language disorders in Spanish-speaking 5-year-olds. However, its use for children of younger ages, or those with bilingual development, has not yet been established. Gutierrez-Clellen et al. also warn against counting episodes of code-switching (going from Spanish to English forms within an utterance, or vice versa) as errors.

As we discussed in Chapter 2, language samples can be used for a variety of purposes. Cheng (1987) suggested collecting language samples from several tasks to look at pragmatic skills in a CLD child. These tasks included relating a past experience, describing an object, and describing a picture. Samples collected can be used to look at language function as well as form and content, as Stockman's (1996, 2008) data illustrate. Bernstein (1989) found this approach to be particularly helpful in getting a broad picture of the communicative skills of CLD children from a variety of backgrounds.

Terrell et al.'s PCCA (1992) also can be applied to language sample analysis. Here a speech sample using a similar sampling context, such as relating a personal experience or narrating a story, would be collected from both parent and child. Again, the child's

linguistic patterns—in terms of syntax, semantics, phonology, or pragmatics, depending on the presenting complaint—would be compared with those of the parent. Any child language characteristics that match those produced by the parent are considered dialectal variations rather than errors. If the child's patterns do not match the parent's, the child's responses are compared with age expectations, using developmental charts and normal language data, such as that found in Haynes and Shulman (1998b), Miller (1981), or Owens (2008). Deviations from Standard English patterns that do not match the parent's and are not typical of normally developing children of the client's age are considered aspects of a language disorder. The PCCA is especially useful for analyzing speech that is influenced by languages or dialects with which the clinician has little experience and for which there are no published data on typical variations from SAE or interference points with English. Comparative analyses can also be done by comparing a child's speech to that of another, typically developing child from the same language/cultural group (Goldstein, 2000).

Some of the measures we discussed as indices of language dominance also can be used to elicit and analyze samples of spontaneous speech from CLD children. These include the *Assessment Instrument for Multicultural Clients* (Adler, 1991, 1993), the *Basic Inventory of Natural Language* (Herbert, 1977), the *Bilingual Syntax Measure* (Burt, Dulay, & Hernandez-Chavez, 1975), and the *Oral Language Evaluation* (Silvaroli & Maynes, 1975). These procedures provide a somewhat structured method of analyzing natural conversational data. Each requires the child to produce a short language sample using a picture description or picture sequence task. Criteria for evaluating the language produced in both English and the home language are provided in the manuals for these procedures.

Other Assessment Procedures

A variety of alternative approaches to making the distinction between language difference and disorder have been presented in the literature. Roseberry and Connell (1991) found that teaching an invented morpheme to children with LEP reliably differentiated normal bilingual children from those with specific language deficits. The children with LEP who were language impaired were much poorer at learning the invented rule and failed to use the morpheme in naming pictures given during post-teaching probes. Lidz and Peña (1996) and Owens (2004) advocated a similar approach, using mediated learning experiences in a pretest–intervention–post-test format to teach vocabulary items on the *Expressive One-Word Picture Vocabulary Test—2000 Edition* (Brownell, 2000). Both these approaches use dynamic assessment procedures, as we defined them in Chapter 2. Dynamic assessment, you'll remember, attempts to determine the degree to which mediation in the learning processes assists a child in grasping new material. For children who can benefit from this mediation, normal language-learning capacity can be inferred. For those who do not find the mediation helpful, underlying deficits in language-learning ability may be present. Approaches such as mediated learning, dynamic assessment, and language processing evaluations like the ones we discussed earlier are especially promising because they can be used no matter what first language the client speaks and regardless of the clinician's familiarity with or access to normative developmental data regarding the first language.

Restrepo (1998) identified a set of measures that discriminate language difference from disorder in Spanish-speaking 5- to 7-year-olds. Her analysis showed that high sensitivity and specificity could be achieved with only two of the measures: parental report of the

child's speech and language skills and the number of errors per T-unit (see Chapter 11) in a speech sample derived from three contexts (picture description, interview, and story retelling). The speech samples were collected in Spanish and analyzed by a native Spanish speaker for morphosyntactic errors. Findings suggest that more than 10 errors per 50 T-units and more than 10 speech or language problems reported by parents on a form such as the one in Figure 5-3 are sufficient to identify a child as having a language disorder in Spanish. Similarly, Patterson (2000) reported that using parent reports of vocabulary size and ability to combine words provided valid information about whether bilingual Latino 2-year-olds were acquiring language normally.

Of course, these methods will only help to decide whether a child with CLD really has a language problem—the screening aspect of our assessment. If, with the help of these procedures, we decide that a CLD child would benefit from intervention, we will still need to do additional assessment to establish baseline function and document progress in intervention, just as we would for any client. For these purposes, both the criterion-referenced procedures we've discussed and observational methods will be helpful.

Using Behavioral Observation with the CLD Child

In Chapter 2, we talked about using behavioral observation to describe aspects of a child's communication when our concern is not to compare the child to some standard but simply to get a picture of current communicative skills. Figure 2-14 gives an example of a form that we might use to look at communicative competence, and this form is appropriate for CLD as well as for mainstream clients (Erickson, 1987). Clinicians can devise other forms to look at behaviors of interest as well.

Cheng (2002a) and Crago and Cole (1991) have argued for the importance of ethnographic assessment with CLD children. Ethnographic assessment differs from other forms of naturalistic behavioral observation in that we may not know ahead of time exactly what categories and attributes of behavior we wish to examine. We are using the ethnographic method because of our unfamiliarity with the cultural norms of the child being observed and will use the observation itself to discover the relevant parameters.

Crago and Cole discussed several methods of ethnographic assessment. These included participant observation, audio and video recorded data, and open-ended interviews. Participant observation is described as "hanging around and taking notes" (p. 114). The clinician watches and may participate in a natural interaction, taking brief notes to be expanded later, to get a rounded and unencumbered view of a set of events. Although participant observation is usually easier to accomplish than, say, videotaping a child in a classroom or on the playground, notes of the participant observation are usually less inclusive than transcripts of a recording. The relative advantages of each method need to be weighed before deciding what method to use in observing a particular child. Open-ended interviews with families of CLD children are another method of gathering ethnographic information about the communicative competence of the CLD child. McCracken (1988) suggested that interviewers develop a series of skeletal questions, without preconceived categories of response, and proceed by a series of indirect prompts for further information while listening carefully for signals that topics are inappropriate or that miscommunication has occurred. Kummerer, Lopez-Reyna, and Hughes (2007) reported on a study that used open-ended interview data.

(More than 10 "yes" responses indicate significant language problems in 5- to 7-year-olds)*

In comparison with other children of the same age, do you think that your child has problems expressing himself/herself or being understood?	Yes	No
In comparison with children of the same age, do you think that your child has speech problems?	Yes	No
Do your family or friends think that your child is delayed in language?	Yes	No
For his/her age or in comparison with other children, does your child have difficulty producing correct phrases?	Yes	No
Do your family or friends think that your child is difficult to understand?	Yes	No
For his/her age, does your child produce very short phrases?	Yes	No
Do you think that your child has problems with grammar?	Yes	No
When your child talks about the same person, does he/she have difficulty using the correct pronoun such as <i>he, she, they</i> ?	Yes	No
When your child talks about something that happened, does he/she have difficulty explaining when this happened or use words in different times; for example, talking about yesterday, does the child say "fall" instead of "fell"?	Yes	No
Does your child make mistakes in sentences more than a little of the time?	Yes	No
When your child talks, does he/she have difficulty expressing whether he/she is talking about a man or a woman?	Yes	No
In comparison with other children of the same age, does your child use many words that are too general and not descriptive or exact, such as <i>this, that, or thing</i> ?	Yes	No
Does your child have difficulty finding the exact words to express himself/herself?	Yes	No
Does your child have difficulty explaining or describing things?	Yes	No
Is it difficult for your child to tell you what he/she did during the day?	Yes	No
Is your child frustrated because he/she cannot talk well?	Yes	No
Do you or your child's brothers and sisters have to repeat what you say to him/her more often than when talking to other children?	Yes	No
Do you have to repeat questions or directions to your child more often than to other children?	Yes	No
Does your child have trouble understanding more than a little of what he/she is told?	Yes	No
Do you think that your child has trouble learning new words?	Yes	No
In comparison with children the same age, is it difficult for your child to learn new ideas?	Yes	No
In comparison with children the same age, does your child have a very low or limited vocabulary?	Yes	No
Do you think that your child has a learning problem?	Yes	No
Does your child have dyslexia?	Yes	No
For his/her age, does your child have difficulty paying attention for a long period?	Yes	No
Is your child hyperactive?	Yes	No
Does your child have difficulty attending to an activity or game?	Yes	No
For his/her age, does your child have difficulty pronouncing words?	Yes	No
Is your child's pronunciation easy to understand?	Yes	No

LANGUAGE INTERVENTION WITH THE CLD CHILD

Once a language disorder has been identified and baseline function in the dominant language has been established, intervention for the CLD child generally follows the guidelines we discussed in Chapter 3. We need to address a few problems particular to CLD children when we plan their intervention programs, though. The first type of problem arises when we find that a child who is not SAE dominant has a language disorder. If an SLP who is fluent in the child's dominant language or dialect is not available, how should intervention be managed? A second problem concerns the child who is progressing adequately in the dominant language or dialect but has limited proficiency in SAE or uses a nonstandard dialect. What is the SLP's role with this client? Thirdly, we have a problem in making our intervention culturally appropriate. How can we be sure of not creating just another setting in which cultural differences get in the way of communication and learning? Let's take these questions one at a time.

The Monolingual SLP and the Client Dominant in a Different Language or Dialect

Because SAE proficiency is so important for access to mainstream culture and its economic opportunities, children with language disorders who speak a language or dialect other than SAE should, at some point, be given the opportunity to learn to communicate in Standard English. In early stages of intervention, however, research (Cobo-Lewis, Eilers, Pearson, & Umbel, 2002; Lopez & Greenfield, 2004; Perozzi, 1985; Perozzi & Chavez-Sanchez, 1992) suggests that instruction in a client's native language facilitates the development of both the first language and English. These findings indicate that early stages of intervention for CLD children with language disorders should be given in the native language, whenever possible, with gradual transition to intervention and instruction in English. When a clinician fluent in a client's native language is available, this approach is clearly preferable.

Too often, however, in a diverse society such as ours, clinicians who speak the language or dialect of every client on the caseload are not to be had. Take Lilly's case, for example.

Ms. Engle was an experienced SLP who had worked for 10 years in a pediatric hospital. But she had never been confronted with a problem such as the one she faced when Lilly found her way onto her caseload. Lilly's family had recently emigrated to the United States from China, and no one in the family, including Lilly, spoke much English. Lilly had recently, at age 4, suffered a series of seizures, and her language use in her native dialect of Mandarin Chinese appeared to be deteriorating. Distraught, her parents brought her to see doctors at the hospital, using friends in the neighborhood as interpreters. Ms. Engle used parent interviews, a speech sample carefully translated in collaboration with the neighborhood interpreters, and some developmental scales and modifications of standardized tests to establish that Lilly's language had been normal when she was younger but had indeed gotten worse since the seizures. Lilly appeared to be communicating at a telegraphic level, to have difficulty understanding anything beyond simple one-step commands, and to rarely initiate communication. In addition to medication to control the seizures, the diagnostic team at the hospital recommended language intervention. Since Mandarin Chinese was Lilly's first, and at this point, only language, Ms. Engle believed it was important to deliver the intervention in that language. Ms. Engle, however, did not speak this dialect.

Juarez (1983) suggested that direct therapy with a monolingual SLP is not the optimal approach for clients with language disorders who are dominant in a different language or dialect. However, as Goldstein and Iglesias (2006) point out, there are important services the monolingual SLP can provide, including in-service training, consultation, diagnostic service, and paraprofessional training. Chabon, Brown, and Gildersleeve-Neumann (2010) provide an ethical perspective on this issue.

In-Service Training

The SLP can train ESL and classroom teachers who work with these clients. Training can focus on topics such as normal language acquisition processes, the relation of communication to language development, the importance of interaction in language acquisition, appropriate and inappropriate uses of standardized tests, informal and criterion-referenced assessment procedures, techniques for eliciting and evaluating language samples, methods of designing language intervention programs, and the differences between "home" and "school" talk (van Kleeck, 2007). The SLP also can provide answers to some of the most commonly asked questions about CLD children with language disorders. These questions include the following:

1. Did the child's bilingual background cause the language disorder?

The answer to this question is a definitive *no*. Cheng's (1996), Owens' (2009), and Thordardottir's (2005) reviews of a broad range of literature on this topic concluded that normally developing bilingual children acquire both languages at a comparable rate, with no deficits in either language. Kay-Raining Bird (2006) and Restrepo (2005) showed that children with intellectual disability growing up in bilingual home environments learned two languages at the same level as did children with similar disabilities learning just one. Even children with significant developmental disorders were able to

acquire two languages with no greater delays than their monolingual counterparts. The key to development is the opportunity to hear and use both languages in familiar, interactive environments. This, of course, may not be the case for many CLD children who hear the minority language exclusively at home and do not encounter the dominant language until they get to school. Still, a child exposed to two languages simultaneously will learn both with no trouble. A normally developing child exposed to one language at home and another at school will go through a period of limited English proficiency but will communicate normally in the home language and will eventually master the dominant language, given adequate opportunity. Most normally developing bilingual children learn enough English to engage in ordinary social interactions (BICS) in 2 to 3 years, although, as we've seen, acquisition of CALP may take more time. So if a child is having trouble in the first language, exposure to the second is not what caused it.

2. Must CLD parents speak to their children only in English?

Again the answer is a resounding *no*. Parents should never feel guilty about using the native language in the home. They should not feel obliged to speak to the CLD child with a language disorder in English, if English is not their own first language. Research (Cummins, 1981; Ramirez & Politzer, 1978) has shown that it is the quality of the language input that makes a difference in development, not the particular language spoken. Parents should be encouraged to engage in many kinds of communicative interactions with their children, including reading books to them, telling them stories, engaging in pretend play, and hearing and telling personal experiences. The language in these interactions should be the one in which the parent is most comfortable and fluent. In this way, the child can receive an optimal model of language structure and function that serves as a strong foundation for development in both languages.

3. Can a language disorder exist in one language and not the other?

Once more, the answer is *no* (Cummins, 1981; Juarez, 1983; Kay-Raining Bird, 2006). If a child has a deficit in the first language, that deficit will affect the acquisition of English as well. If a child is developing normally in the first language, on the other hand, but has limited English, the problem is most likely to be lack of adequate opportunity to develop English language skills. This lack of opportunity may be a result of recent arrival in the United States, in which case time and understanding teachers may be all that are needed to solve the problem. The lack of opportunity could also stem from social isolation, though. A CLD child may be exposed to English only in limited, formal contexts in school and interact exclusively with people who speak the minority language at all other times. The monolingual SLP can make this clear by observing the child in school. The SLP can document who the CLD child spends informal time with during recess and lunch and what language is spoken.

If it turns out that the CLD child is socially isolated from English speakers, the SLP can use the in-service training setting to encourage teachers to foster some social interaction. This might include helping teachers to arrange an English-speaking "buddy" to pair off with the child during some informal parts of the day; organizing sports, craft activities, or games between mixed groups of CLD children and English-speaking classmates during recesses; or developing a lunchtime club with invited members from both linguistic groups who

get to eat in a special place (such as the teachers' room) and talk together in English. For normally developing children with limited English skills, such social interactive opportunities go a long way toward building English proficiency.

Damico and Damico (1993) discussed the process of acculturation in students from linguistically and culturally different backgrounds. They emphasized that a crucial factor in acculturation is the degree to which a person feels affiliated with the mainstream culture. An attitude of acceptance and respect on the part of mainstream professionals is certainly an important factor in creating this feeling of affiliation. In addition, however, teachers and clinicians who work with children from culturally different backgrounds would perform a service by setting up opportunities for playground or extracurricular interactions with SAE-speaking peers. These interactions will go a long way toward developing feelings of solidarity with the dominant culture that provide ELL children the motivation to improve their English language skills.

Consultation

In addition to training teachers in general techniques for developing language skills in children, monolingual SLPs can consult on the interventions for particular CLD children with language disorders. Clinicians can work with teachers to increase their use of culturally sensitive teaching strategies, such as those discussed in the "Multicultural Teaching Techniques" section. We also can encourage the use of script-based interventions, literature-based scripts, and many of the other intervention strategies we discussed in Chapter 3. Clinicians can demonstrate in English how to use such approaches, so the bilingual staff can adapt them to the minority

language. Salas-Provence and Oprandy (2006) provide additional ideas, and ASHA suggests guidelines for educational modifications for ELLs, which appear in [Box 5-11](#). A wealth of other resources can be found at www.asha.org/practice/multicultural.

SLPs also can, in collaboration with other staff, develop child-centered or curriculum-based language activities that can be translated by the bilingual staff. These would involve consulting with bilingual staff about the language status and goals for particular clients and about the current classroom themes and curriculum. The SLP can then design a set of activities to address these goals in the context of classroom themes and can consult with staff about translating this program into the child's first language.

In addition, SLPs can fulfill their consultation role by becoming familiar with new tests and materials that address particular language groups. As [Appendix 5-2](#) amply demonstrates, a variety of tests are available in several languages. As time goes on, more materials in more languages will come onto the market. The SLP can serve as a resource for bilingual staff by watching for and alerting them to new materials in the languages of their clients.

SLPs consulting to classroom programs with CLD children also are important in helping decide when to introduce or focus more sharply on instruction in English. Since CLD children with language disorders should have the opportunity to develop English-language skills, the monolingual SLP needs to observe their progress to determine when some intensive intervention in English is warranted. This involves careful monitoring of both English and first language skills. Using the techniques for assessing first language and SAE skills in CLD children that we talked about earlier, the clinician can use both standardized and informal procedures to

BOX 5-11 English Language Learners in Schools Checklist for Educational Modifications

CLASSROOM ROUTINE

- Establish a daily routine
- Provide optimal seating so that the student can easily see the materials and hear the instructor
- Review and summarize prior lessons
- Set up "partners" in order to team a student who is an English language learner with another student
- Teach book format (e.g., table of contents, glossary, directionality of text)

LESSON PLANNING

- Consider background of students when planning appointments, community outings, holiday celebrations, meals and snacks; for example, not all children may celebrate the same winter holiday
- Consider the cultural and linguistic background of students when selecting materials (for example, pictures, books/workbooks, flashcards, videos, music, food, etc.)
- Plan for small group activities to allow children to rehearse speaking skills
- Present frequent review and repetition
- Provide a blank outline, chart, or web to fill in during class
- Use a consistent format for worksheets with minimal graphic distractions

DAILY INSTRUCTION

- Allow multiple methods of sharing experiences and communication, for example, use of storytelling and props that support the oral tradition
- Allow extra time
- Ask specific questions
- Learn and appropriately use key words in other language(s) (for example, hello, please, thank you, etc.)
- Present information in short, sequential steps
- Provide hands-on instructional materials
- Use multisensory cues for instruction
- Use visual aids, gestures, and physical prompts
- Write instructional key words on the board

Bilingual SLPs can deliver services in clients' first language.

track growth in each language. Criteria we might use to make the decision to introduce English-language intervention include the following:

1. The client's English skills have progressed to about the same level as first language skills. English-language intervention can "shadow" forms and functions being acquired in the first language.
2. The client has reached a plateau in first language learning and is not making rapid progress. English skills commensurate with those in the first language can be targeted. Miller (1984) suggested that language intervention in English should begin with features the child already knows in the first language.
3. The client has been in a bilingual program for a considerable time. English intervention can be introduced to begin the transition to more participation in the mainstream program.

Diagnostic Services

Monolingual SLPs have the obligation to determine whether a CLD child is different or disordered in communication skills. This diagnostic responsibility can be fulfilled by using all the techniques we talked about before, including establishing language dominance, training interviewers and obtaining interview data, using and modifying standardized tests, doing speech sample analyses and other criterion-referenced assessment, gathering information from behavioral observation of the child, doing dynamic assessments, and getting ethnographic information about cultural styles of communication from bilingual members of the community.

Training Paraprofessionals to Deliver Services in the First Language

When professional staff such as ESL teachers or bilingual clinicians fluent in a client's language are not available, we may be able to draw on bilingual paraprofessionals, aides, or community volunteers to deliver first-language services (Kohnert, Yim, Nett, Kan, & Duran, 2005). SLPs may sometimes need to recruit such people to assist with their programs for CLD children with language disorders. Community agencies, churches, and local colleges and community colleges can be contacted to locate bilinguals willing to work as aides or volunteers to teach language skills to children in their cultural group.

The monolingual SLP has the responsibility to plan out the client's program and train the paraprofessional to deliver it. Again, the SLP will need to complete the diagnostic process and arrive at goals for first language learning. Commercially available materials in the first language can be selected and assembled to address some of the goals. The SLP can carefully review the procedures for use of these materials with the paraprofessional.

The SLP can train the paraprofessional to use the child-centered language approaches we talked about in Chapter 3 when working with clients in early stages of first language acquisition. These include, you'll remember, indirect language stimulation or facilitative play. The clinician can train the paraprofessional to engage in child-centered activities and provide enriched input in the form of self-talk, parallel talk, recasts, expansions, and extensions in the client's first language. Literature-based script activities also can be taught to the paraprofessional, with an emphasis on clear and repetitive input paired with engaging activities and materials selected to highlight vocabulary and language forms and functions that the child needs to develop. Focused stimulation and clinician-directed activities also can be designed by the clinician and translated in collaboration with the paraprofessional.

When working with a paraprofessional, of course, the SLP maintains the responsibility to monitor progress in the intervention program, by reviewing assessment data gathered by the paraprofessional in the course of the program. The SLP will be the one to decide when to introduce new goals, when to modify procedures, when to terminate intervention, and when to switch to English language instruction or to pair intervention in the two languages.

ASHA (1998, 2004c) has provided guidelines for monolingual SLPs working with clients who speak another language. These are summarized in [Box 5-12](#).

The Worst-Case Scenario

Suppose you have a certain CLD child with a language disorder on your caseload. You don't speak her language and neither does anyone else in your facility; there is no ESL program in your area; the client's parents do not speak English; and you've been unable, after some effort, to recruit a community member to work with her. What can you do? Kohnert et al. (2005) suggest one alternative: recruiting typical peers from the same language group to provide peer mediation. Peers from the client's language community can be taught simple strategies, like those used in "Buddy Time" (English et al., 1997), in which buddy pairs are assigned for a period of the school day and the buddy's job is stay with and talk to the client for the entire period in order for both to earn some reward. Such simple strategies can provide the client with intensified opportunities to practice the home language.

At the same time, the clinician can deliver appropriate intervention in English. We would want to assess, as well as we can, where the child is functioning in the first language to get some sense of baseline function. Then we would begin using indirect language stimulation with age-appropriate materials. When the child has begun to use English in this setting, some script-based or focused stimulation activities can be introduced. We would proceed essentially as we would with a child in the emerging language stage (see Chapter 7). Vocabulary and themes can be related to classroom work if the client is in school. The combination of peer mediation in the home language and clinician-delivered intervention in English can help to shore up both forms of communication (Restrepo, 2005). ASHA (2008) and Peña and Fiestas (2009), Pederson and Vining (2008) provide guidelines for SLPs working with CLD preschool children and toddlers.

BOX 5-12 ASHA Guidelines for Monolingual SLPs Working with Clients Who Speak Another Language

Monolingual SLPs may do the following:

- Test in English
- Perform oral-peripheral exams
- Conduct hearing screening
- Complete nonverbal assessments
- Conduct family interviews with appropriate support personnel
- Research client's language and culture
- Advocate and refer

Monolingual SLPs should seek help with CLD clients by doing the following:

- Establishing contacts and hiring bilingual SLP consultants
- Establishing cooperative groups among several school systems to hire bilingual SLPs
- Establish networks and links between universities and clinical setting to recruit and train bilingual SLPs
- Establish Clinical Fellowship Year and graduate student practicum sites for bilingual SLPs training
- Establish interdisciplinary teams in which monolingual SLPs collaborate with and cross-train bilingual professionals from other fields
- Recruit and train support personnel from the community to serve as bilingual aides and paraprofessionals
- Follow ASHA guidelines for supervising bilingual support personnel

The SLP and Normally Developing Children with Limited Proficiency in Standard English

Several court cases (*Lau v. Nichols*, 1974; *Martin Luther King Junior Elementary School Children et al. v. Ann Arbor Michigan School District Board*, 1979) have ruled that it is unconstitutional for schools to fail to take into account the languages with which children come to the classroom. These decisions do *not* mean that students' home languages must be the language of instruction. They do mean, however, that public institutions have the obligation to educate teachers about students' native languages or dialects and to attempt to eliminate negative attitudes and diminished expectations on the part of teachers based on their perceptions of their students' language differences. Ms. Salford's story shows how such attitudes can affect adults' perceptions of CLD children.

SLPs working with children with LEP can provide social opportunities to interact with SAE speakers.

Ms. Salford was a new SLP in an inner city school with about 90% African-American and Hispanic-American students. When she arrived, she noticed that the students rarely talked to adults unless they were directly asked a question. On the playground students did lots of talking, yelling, and arguing, but inside they were mostly sullenly silent. Teachers complained that the students had "poor verbal skills" and were "language delayed" and wanted large numbers of students included on Ms. Salford's caseload for language intervention. Ms. Salford sat in on a few classroom sessions to learn more about the students' communication skills. She noticed that the teachers frequently corrected their students, insisting that they use "proper" English when they talked. Students were often told that the teacher couldn't understand them, that their speech was "sloppy." Yet in her playground observations, Ms. Salford heard sophisticated verbal negotiations and a lot of creative use of language for ritualized, playful put-downs. She even heard students getting together in small groups in corners of the playground to add verses and make up new lyrics to their favorite raps. She began to suspect that there was a serious discrepancy between what she heard on the playground and what the teachers were reporting about the children's language skills.

When a normally developing CLD child has LEP, the SLP needs to decide, based on thorough assessment in both languages or dialects, that the child is indeed developing normally in the first one and is limited in SAE only. For these children who do not have a disorder, but rather have a limitation in the use of Standard English, direct services by the SLP are usually not indicated. Still, as Fitts (2001) reminded us, even though LEP or use of nonstandard

dialect may not be a disorder, it can constitute a social and educational handicap. Blake and van Sickle (2001) and Mehan (1984) emphasized the importance of being able to master the code of classroom language to succeed in school and thereby obtain wider opportunities for economic advancement and security. As we've seen, children who have BICS in English may not have achieved the level of CALP that supports success in school (Roseberry-McKibbin, 2008). In light of the importance of using and understanding SAE to "make it" in the mainstream, a legitimate aspect of our scope of practice can be to offer our expertise to professionals who deal with normally developing ELLs, even when we don't provide services to these children directly. ASHA (2002) provides guidelines for these kinds of services, and considers them *elective*, rather than required. The main roles we will generally play in this enterprise will be in terms of in-service training and consultation.

In in-service presentations to other professionals and in consultation activities, we will want to emphasize the importance of creating social opportunities for ELLs to interact with SAE speakers. Taylor (1986) gave some suggestions for encouraging the development of a second language or dialect through interaction. These are summarized in [Box 5-13](#). In addition, many of the recommendations that we talked about earlier for creating social opportunities for CLD children also are applicable here.

Another aspect of our responsibility for educating other professionals about CLD concerns the need to convey the importance of language skills for success in the classroom. We need to help our colleagues see how language skills pervade the curriculum at all levels, from preschool through secondary grades. Some of the suggestions for in-service training given in Chapter 12 can be used to make this point. To take it one step further for the CLD child, Adler (1990) emphasized that we need to make colleagues aware of how negative attitudes about language differences can affect children's performance. We also need to help minimize the handicap conferred by a language difference by increasing colleagues' awareness of the problem.

Blake and van Sickle (2001) stressed that improving SAE does not mean eliminating the nonstandard dialect or use of the minority language. On the contrary, programs aimed at improving SAE in culturally different children should have the aim of helping children become bilingual or bidialectal code-switchers (that is, speakers able to move back and forth between language styles,

choosing the one most appropriate for the situation). For example, Lugo-Neris, Jackson, and Goldstein (2010) showed that reading Spanish-speaking preschoolers books in English, and providing explanations of unfamiliar English words in Spanish produced greater gains in the children's use of expressive definitions than English-only instruction. Connor and Craig (2006) showed that AAE-speaking preschoolers were already capable of code-switching, and suggest this ability may serve as a foundation for metalinguistic skill development. Additional ways to develop bilingual and bidialectal abilities include providing instruction not only in SAE forms, but also engaging children in discussion of the functions of a variety of communicative styles. As a metalinguistic approach, this sort of intervention is ideally adapted to classroom situations. Talking about language use is a metalinguistic activity that will benefit all students, not just those who are CLD. Let's look at some specific techniques we can present to colleagues as consultative suggestions for classroom programming in this area.

Cole (1985) suggested a variety of activities that can be used to teach SAE as a second dialect to AAE speakers, many of which are applicable for children with LEP as well. These are outlined in [Box 5-14](#).

Taylor (1986) presented a detailed program for developing skills in SAE for children who speak a nonstandard dialect. This program is referred to as *A Cultural and Communication Program for Teaching Standard English as a Second Dialect* (ACCPT, pronounced as "accept," for short). These procedures also can be adapted for bilingual children with LEP. The sequence of instruction in this program is schematized in [Figure 5-4](#).

The first and perhaps most crucial step in this program is developing positive attitudes toward the children's own language or dialect. This requires, of course, that the teacher have such attitudes as well. The SLP can be very important in this process by using in-service training opportunities to talk about the legitimacy and importance of having a strong base in the home language or dialect on which SAE proficiency can be built. At the same time, the SLP can encourage teachers to convey an accepting and positive attitude about the home language or dialect to students. Taylor (1986) suggested that students be introduced to the idea that each culture has its own language and to see language as a tool for communication that can be looked at and be of interest for its own sake. Activities such as learning a simple song, rhyme, or finger play in each of several languages can be a first step. The teacher can convey acceptance of the students' own language or dialect through activities such as asking students to bring in songs or games that they play at home and teach them to the group or asking the students to "teach" how they greet someone in the home language or dialect.

The next step in this program involves developing an awareness of language differences, first in general and later in contrasting the home language or dialect with SAE. Adler (1993) suggested that students be taught to recognize two different language styles, designated "everyday talk" and "school talk." Two puppets might be introduced, one who talks everyday talk and one who talks school talk. Children can be encouraged to listen to how the puppets talk differently and decide which puppet uses which style. Next, pictures of different settings, such as classroom, playground, doctors' office, and kitchen, might be shown. Children can be asked to say whether everyday talk or school talk would be most appropriate for each setting. Van Kleeck (2007) provides additional ideas.

Additional activities can include reading poems and stories in "old" or more archaic forms of English. Classic poems such as

BOX 5-13 Principles for Developing Second Language or Dialect Skills

1. Give children opportunities to engage in genuine, spontaneous conversations with peers.
2. Create situations in which some information is missing, so the child must identify the gap and request more information.
3. Set up goal-oriented conversations with peers, such as assigning children to cooperative learning groups in which they must complete a class project. Be sure that the CLD child has opportunities to negotiate verbally with the other members of the group.

BOX 5-14 Methods for Teaching English as a Second Dialect or Language

1. **Modeling and expansion.** The instructor models the SAE version of a child's utterance, making no direct attempt to change the child's production. The SLP works with the teacher to identify a small set of forms to be especially careful to notice and model whenever they appear in the child's speech. When use of these forms moves closer to SAE usage, new forms can be targeted.
Example: If an AAE- or Spanish-speaking student in the class has difficulty using SAE negative marking, a child who remarks, "He no like beans" can be told, "You're right. He doesn't like beans."
2. **Script-based approaches.** Specific forms are targeted by teaching the group a script based on a song, story, poem, finger play, or chant.
Example: If a Hispanic child in a class has difficulty using comparative endings, the group might be taught the song "I Am Bigger" to the tune of "Where Is Thumbkin?" Each student adds a verse to the song, after several models by the instructor. Each verse has the following form:
 "You are big, but I am bigger. I am bigger, I am bigger" (You are X, But I am X-er).
3. **Call and response:** This is a type of interaction between a speaker and group of listeners in which calls from the speaker elicit responses from the group. Responses can be either scripted or spontaneous. For scripted responses, the teacher establishes a classroom routine, to which students are expected to respond when they hear a particular call. For example, when a child uses a "school talk" form spontaneously, the teacher might ask the group, "What do we say to that?" who respond, "Smooth talking; give your back a pat!" Spontaneous responses use the teacher's call as a guide; usually these include requests the repetition. Foster (2000) provides the following example.
Example: When teaching a new word such as *paleontologist*, the teacher (T) might say to class (C):
 T: Here's a new word we need to learn for our dinosaur study. The scientist who studies dinosaurs is a paleontologist. How many parts to that?
 C: Six
 T: Ok, let's say the first three together: pay lee on
 C: pay lee on
 T: Yes, just like when you owe your friend, you'll say I am gonna Pay Leon!
 C: Pay Leon
 T: (whispers) Pay Leon
 C: (whispers) Pay Leon
 T: (louder) PAY LEON
 C: (louder) PAY LEON
 T: OK! PAY LEE ON to lo gist
 C: to lo gist
 T: Let's say the whole word, FAST: pay lee on to lo gist!
 C: Pay Leon tologist
4. **Literature-based scripts:** The group reads or listens to a story selected to give numerous examples of a target form (see Appendix 9-1 for an extensive list of examples of such stories). After the first reading, children participate in telling the story by acting it out, using flannel board figures or similar means. Students fill in parts of scripts of the story as the instructor rereads it.
Example: If a CLD child has trouble with subjective pronoun use, *The Very Busy Spider* (Carle, 1984) can be read to the group and acted out. The CLD child can be asked to narrate some sections of the acting-out, so that opportunities for using the subject pronoun ("She was very busy . . .") are provided.
5. **Dialect stories.** Stories are read to the group that contain characters from the same cultural group as the CLD child. The speech of the characters is read in dialect, whereas the rest of the text is read in SAE. The instructor has the children contrast the two styles, talk about how they differ, and explain why different styles are used in different parts of the story. The dialect sections can be "translated" into SAE and the SAE sections into dialect or into the CLD child's first language by the CLD child. Again, the group can discuss the differences.
Example: The group can read *Liza Lou* (Meyer, 1976), *We Be Warm Til Springtime Comes* (Chaffin, 1980), or *Cornrows* (Yarbrough, 1981). The characters can be given dialogue in AAE by AAE speakers in the group. These forms can be contrasted with the way the rest of the story is written.
6. **Situational contrastive drills.** Children act out a variety of everyday situations, using both SAE and the home language or dialect. They are encouraged to talk about which is appropriate for each situation, to list situations in which they might use one or the other. They can brainstorm about why "home talk" is appropriate at home, but a different "school talk" form is needed at school or in more formal situations.
Example: Suppose Marta's dad runs out of gas on his way to work. He walks to a gas station near his job. What do he and the gas station attendant say to each other? What if he ran out of gas right near his apartment, where nearly everyone speaks Spanish and walked to the station right on his corner. What would he and the attendant say to each other then? How do we decide which way to talk?

Adapted from Cole, L. (1985). *Nonstandard English: Handbook for assessment and instruction*. Silver Spring, MD: L. Cole.

BOX 5-14 Methods for Teaching English as a Second Dialect or Language—cont'd

- 7. Linguistic contrastive analysis.** The instructor gives the children examples of specific contrasts of standard and nonstandard forms. The student contrast the two versions of each form to find out about the rules that differentiate the two types.

Example: Here are two ways to say the same thing:

"I look for him last week." "I looked for him last week."

"I walk to school yesterday." "I walked to school yesterday."

"I help the teacher a lot last year." "I helped the teacher a lot last year."

How are the two ways of saying the same thing different? Can you say what the rule for the first speaker is when talking about things that happened in the past? What about for the second speaker? Which speaker is using "school talk?" "Home talk?"

- 8. Paraphrasing and retelling.** Students listen to or read a story in SAE and retell it in the home language or dialect.

Example: The students read a story, such as a chapter of *Stuart Little* (White, 1974). In cooperative learning groups, they "translate" it into the home language or dialect.

- 9. Role projection.** Students take on a role and respond to realistic situations within their role.

Example: Willy isn't feeling well, so his mom takes him to the doctor. What do Willy's mother and the doctor say to each other as the doctor examines Willy?

Adapted from L. Cole (1985). *Nonstandard English: Handbook for assessment and instruction*. Silver Spring, MD: Author; Foster, M. (2002). Using call-and-response to facilitate language mastery and literacy acquisition among African American student. *ERIC/CLL Digest*, July, EDO-FL-02-04.

FIGURE 5-4 A sequence of oral communication training for bilingual or bidialectal children. (Reprinted with permission from Taylor, O. [1986]. *Treatment of communication disorders in culturally and linguistically diverse populations* [p. 168]. Austin, TX: Pro-Ed.)

Mary Howitt's "The Spider and the Fly" or Henry Wadsworth Longfellow's "The Midnight Ride of Paul Revere" might be used. Children can retell each in their own language, the teacher can retell them in contemporary SAE, and the retellings might be recorded for later contrastive analysis. Typing 'Lingo Kid' into YouTube's search engine produces a video of a child peddler describing his wares in ten different languages, and may serve as a

stimulus to discussion. Children also can listen to different regional dialects (putting the search term "accent" into YouTube's search engine yields a variety of videos of a large range of accent types) recorded by the instructor from popular television shows or podcasts and "translate" these scripts into the home dialect.

Steps III and IV of Taylor's scheme involve recognizing and labeling differences in the form and meaning of messages sent in

standard and nonstandard styles. For children beyond the primary grade levels, analysis of form could include contrastive linguistic analyses and attempts to characterize the rules for use of the different languages or dialects. Work on comprehending meanings of various forms of the same message can involve talking about the different meanings words can have in different dialects (When does *sick* mean “not well” and when does it mean “cool” or “hip”?). Wheeler (2005) has shown that contrastive analysis and encouraging code-switching through awareness of differences between dialects works better than merely correcting dialectical usage. She argues that correcting children’s dialect use is ineffective (Wheeler & Swords, 2004), and leads to increasing gaps between SAE and AAE speakers as they progress through school. Wheeler shows that contrastive analysis with an emphasis on conscious code-switching results in significant decrease in the use of AAE features in writing, and in consequent narrowing of the achievement gap.

Looking at the situational requirements for different language styles (Step V) can involve role-playing and metalinguistic discussions of the needs of speakers and listeners in different communicative settings. Activities such as those suggested in [Box 5-14](#) can be used in these contexts. In Step VI of Taylor’s sequence, children are given practice and support to produce forms in SAE in structured situations. One kind of structure that can be employed is the call-and-response form. This form has a long history in African-Americans traditional discourse (Cazden, 1999) and may be familiar to students for this reason. Foster (2002) reported that primary classrooms whose teachers used call-and-response improved reading and code-switching to SAE more than classrooms that did not use the technique. A description of call-and-response discourse appears in [Box 5-14](#). Taylor also suggested activities such as choral reading and Readers’ Theater, in which students read short poems or stories of their own choosing to an audience. The poems and stories in this exercise are in SAE style. Step VII involves similar activities with somewhat less structure and support. Students use role-playing and story-telling contexts to produce SAE forms. In these activities, the content of the message is familiar and predictable. Familiar situations, such as visiting a doctor, ordering a hamburger, or buying shoes at the store, would be appropriate for role-play in SAE style. Retelling an often-heard story, such as the plot of a popular movie or TV episode or a folktale well-known in the community, is another vehicle for this level of instruction. Although the students must produce their own spontaneous language in SAE style, the task is somewhat more constrained than normal conversation, providing the students with a better chance to focus on the SAE forms, since the function and content of the message have already been determined for them.

Blake and van Sickle (2001) suggest using a Writers’ Workshop approach to address this step for older students. Here, students are encouraged to write about their own experiences in their own dialect. Brief mini-lessons are presented to address writing mechanics and text structures. Students get feedback on their work through dialogue journals, in which teachers comment not only on content, but on dialect features of the writing and make suggestions for changes to SAE. Students then share their writing with the class, and discuss when/how/why they did or did not choose to use dialect features within their compositions.

The final step in Taylor’s program involves spontaneous production of SAE forms in the appropriate context. Here instruction would remind children what they have learned about the different communicative demands of different contexts. Role-playing would be used for less-constrained production activities to allow students

to practice emerging SAE skills. Situations appropriate for this level might include asking a teacher about a homework assignment, giving a formal talk on bike safety to a group of younger students, or telling the student’s life story to a reporter writing an article for the school newspaper.

Brice and Roseberry-McKibbin (2001) and Roseberry-McKibbin (2008) made suggestions for working with children who come from non-English-speaking backgrounds. They emphasized the importance of using the native language as a medium for improving students’ communication in the second language, and outlined a series of strategies for implementing this suggestion in the bilingual or monolingual classroom. These strategies are summarized in [Table 5-8](#), and can serve as helpful consultation suggestions for SLPs working with classroom teachers of children learning English as a second language.

Any of the programs we’ve been discussing, or ideas from them, are appropriate information to share with classroom and ESL teachers in our consulting role. For SLPs who work in schools with large numbers of CLD children, these also are ideal opportunities to do some collaborative teaching, coming into the classroom of a CLD child who does have a disorder and doing activities such as the ones we just discussed to help the whole class improve their proficiency in SAE. When we offer these activities as consultative suggestions, however, we’ll need to remember that it won’t be enough just to do the activities, if the teacher doesn’t convey a genuine sense of acceptance of language difference. Using the collaborative teaching situation may be one of the best ways for us to provide a model of this kind of attitude to teachers who work in classroom settings with CLD children.

Finally, it is good to bear in mind that many of the techniques advocated by writers on ELLs and children with CLD are the *same approaches* recommended for working with children with language-learning difficulties from mainstream backgrounds. Methods such as creating preparatory sets, teaching compensatory strategies, allowing extra time for processing, bringing children’s personal experiences to bear on classroom topics, using simplified, repetitive language in instruction, scaffolding, using focused stimulation to correct grammatical errors, teaching phonological awareness and alphabet knowledge explicitly to promote early literacy, using carefully structured questions to facilitate language production, explicit teaching of curricular vocabulary, and using text structures to facilitate expository comprehension are advocated by Bejos (2009), Lugo-Neris et al. (2010), Mathes et al. (2007), Roseberry-McKibbin (2008), Restrepo and Towle-Harmon (2008), and Thordardottir (2005), just as they are by those working with mainstream children with language problems (see Chapter 12 and 14). For clinicians, this means that working with CLD clients and their teachers does not involve re-inventing the wheel. Many tried and true techniques are helpful for these clients, as they are for others. The additional piece of the puzzle for clients with CLD is to encourage these students to continue to learn and use their home language, and to employ it as a scaffold to competency in English (Kohnert, Yim, Nett, Kan, & Duran, 2005). Burns, Velleman, Green, & Roeper (2010) argue that the issues for speakers of AAE are quite similar, and similar approaches, including encouraging home dialect use in conjunction with SAE, are warranted.

Multicultural Teaching Techniques

How can we make intervention more culturally appropriate and therefore more accessible to CLD children, both with and without language disorders? Tharp (1989) showed that when similarities

TABLE 5-8 Consulting Suggestions for Teachers Working with Bilingual Children in Classroom Settings

Strategy: Encourage Teachers to	Description	Example
Reiterate	Repeat what the other speaker said for emphasis and clarification.	Student: He take it? Teacher: Did he take it? I think he did.
Check and expand vocabulary	Checks vocabulary understanding and use. Introduce new words in English, talk about Spanish equivalents, and discuss vocabulary items explicitly.	Student: I need a . . . Teacher: You need an eraser? You need to erase your answer, to change it? You need an eraser, then. We use an eraser to erase, or get rid of what we want to change. How do you say that in Spanish?
Maintain flexible language environment	Allow students multiple forms of participation in classroom discourse, including flexible turn-taking, increasing wait time for responses, accepting answers in either language, rewards for participation.	The teacher may occasionally respond to a student with “ <i>si</i> ” rather than “yes,” or prompt with “ <i>y que mas</i> ” sometimes, instead of “and what else.”
Value native languages	Convey acceptance and appreciation of multiple languages by recognizing appropriate uses of each language, asking students how to say things in their native languages, including material from native languages within the curriculum.	Teacher reads students a Mexican folktale in English, then asks students, “What’s the word for this bowl in Spanish? How would you ask the girl in the story’s name in Spanish?”
Encourage code-switching	Allow code-switching in student contributions to encourage spontaneous language use.	Encourage students to help others master classroom concepts by presenting what the teacher said in English to peers in Spanish.
Ask questions	Encourage bilingual students to answer teacher questions, in the native language if necessary, to increase class participation and provide opportunities to hear English versions of their Spanish responses.	Teacher: There’s a grandmother in this story. What do you call your grandmother? Student: Abuelita. Teacher: <i>Abuelita</i> , that’s what you call your grandmother? I call mine <i>Gran</i> . <i>Abuelita</i> , <i>Gran</i> , two names for grandmother.
Allow use of home language as a bridge to English	After hearing/reading a story, ask ELLs to summarize the story in the home language first, then in English (Smyk, Restrepo, Gray, & Morgan, 2008).	After reading allow children to break into groups by home language. Let ELLs work together to summarize the story in the home language. Then have groups take turns providing a summary in English.
Provide clear, repetitive, simplified input, along with more advanced forms	Simplified input does not need to replace more advanced language, but it can accompany it.	Ask teachers to paraphrase instructions and important content, after their normal presentation. For example, “This week we’ll be studying the conversion of light to energy by means of photosynthesis. Photosynthesis is the way plants make food. They turn sunlight into food energy by photosynthesis. Photosynthesis gives plants their energy to grow.”

between the school and home culture are increased, the performance of CLD children improved. In both our consulting role with teachers and in our own direct interactions with CLD children, we can incorporate some procedures and activities that will help reduce cultural conflicts. Remember, however, that different cultures will have different expectations. As we saw earlier, Asian-Americans may expect teachers to talk and children to listen, speaking only when spoken to first. Native Americans, on the other hand, may not find speaking in a teacher-directed group a familiar or comfortable experience. The suggestions we’ll talk about here may be helpful for some children from some cultural groups, but no one suggestion will be appropriate for everyone. We’ll always need to use judgment and rely on advice from community members about

what techniques will work best for particular children and cultural groups.

One issue that faces us when we work with children with CLD concerns their view of themselves and their potential. Smyer and Westby (2005) recount what happened when they invited students in a low-income, all-minority school to enter an essay contest for scholarships to a summer science camp. They were surprised when, after a long silence, one of the students replied, “That’s for smart white kids, not us.” (p. 23). Smyer and Westby conjecture that the persistent achievement gap between CLD children and mainstream students has roots in this feeling that only “smart white kids” succeed in school and academic pursuits. They argue that an important aspect of multicultural teaching includes an explicit

Working with culturally different clients may involve teaching SAE as a second dialect.

refusal to accept this assumption, and a concerted attempt to convince the children themselves of their potential as learners. Danzak and Silliman (2005) echo this notion, and argue that becoming a competent English-language speaker involves building a new aspect of identity; that of a “smart kid” who communicates in English at least some of the time. To accomplish this end, Smyer and Westby describe a literature-based program in which they encouraged students to read (or listen to) and discuss stories of individuals, particularly those from nontraditional backgrounds, who had overcome obstacles, defied others’ expectations, and used courage and determination to achieve great things. A list of some of the literature they used in this program appears in [Box 5-15](#). Smyer and Westby also report that, following this literature program, several of their students successfully applied for the summer scholarships. In our consultant and collaborative roles, we can encourage teachers to adopt similar approaches to raising students’ expectations of themselves.

One important aspect of multicultural teaching concerns the role of literacy for the CLD child. Connor (2008) emphasizes the important connection between oral language and literacy development, and the impact of this connection on children with linguistic differences. Since literacy is built on the base of oral language, a mismatch between the language or dialect a child is learning to read and the one he or she speaks will inevitably lead to difficulties. Kayser (2004) reported that the International Reading Association advocates encouraging CLD students to become biliterate as well as bilingual, and suggests beginning literacy instruction in the child’s first language. While this may not be possible for children from smaller language groups, many programs working with Spanish first-language users do adopt this approach. Even if first-language literacy instruction is not possible, however, Kayser suggests SLPs work with teachers of CLD children to improve their literacy development by providing parents with books to read to their children in their native language, and building bridges between home literacy and school. As we’ve seen, Restrepo and Towle-Harmon (2008), as well as Schwanenflugel et al. (2005) and Smyk et al. (2008), also support this approach. Terry (2008) adds that developing metalinguistic awareness, talking about language and dialect differences as part of the literacy program, reading literature that uses different language styles, and role-play that contrasts language use in different contexts is appropriate for children with CLD even in the preschool and primary years.

We talked earlier about some of Westby and Rouse’s (1985) suggestions for working with CLD children with language and learning disorders in classrooms. They suggested adding some high-context activities in the classroom to increase the child’s chances for success there. In addition, they advocated providing parents with structured, lower-context activities to do at home to build these skills in a nurturing atmosphere. Westby and Rouse also suggested using cooking, crafts, and pretend play activities to provide high-context opportunities for language learning. In these activities, the clinician or teacher first introduces the tools or props to be used, names them, and discusses their function. The adult outlines the sequence of activities to be carried out. For cooking or craft activities, this would involve telling the students the steps to follow to complete the project. For pretend play, the adult can set the scene and outline the script (“We’ll pretend to have a birthday party for Maria. First we’ll have to bake her a cake. Someone will have to go to the store to buy . . .”) Children are invited to contribute, but are not singled out or required to give a particular response. The purpose of the interactions is to provide rich, contextualized language input with models of the kinds of discourse appropriate for the situation and to give children opportunities to talk in a non-threatening setting. Children are encouraged to comment and relate personal experiences, rather than to display knowledge as they are in traditional classroom activities.

Westby and Rouse stressed the importance of teaching planning and metacognitive skills to CLD children, since many high-context communicative styles do not place strong emphasis on planning

future activities. They suggested that book reports, particularly reports developed by a group rather than an individual, offer an especially helpful context for developing these skills. Harris (1995) emphasized the importance of allowing CLD children to read or hear the whole story before asking any questions, since this holistic approach more closely mirrors a high-context communicative style.

Having a group of children develop an oral or written book report on a book they have read or listened to is valuable for several reasons. First, the book sets the topic and can be used by the teacher to get a child back on topic if an associative remark is made. Having the group negotiate the best way to retell or interpret the story provides valuable experience in applying metacognitive and metalinguistic processing to a text, such as a remembered story, for which there is little contextual support. Looking for characters' strategies, motives, and attempts to carry out intentions, then evaluating the results of characters' attempts, all help focus attention on the planning aspect of human behavior. Westby and Rouse emphasized that the purpose of all these activities is to help CLD children learn how to learn in a low-context culture such as the classroom and to allow them to use the high-context learning styles with which they came to school to acquire that knowledge.

Harris (1995) suggested modifying the timing and rhythm of presentation of material. Teachers and clinicians are encouraged to give CLD children more time to answer questions and to pause after a child's answer before giving an evaluation. These changes are particularly relevant for Native American children who feel speech needs to be considered carefully before a response is given. When these wait times were increased, Winterton (1976) found that Native American children were twice as likely to participate in classroom interactions as when shorter wait times and fewer pauses were used. Modifying rhythm of presentation means talking more slowly and fluidly, with fewer self-interruptions and digressions. Decreasing the rate of presentation of material will probably benefit many students, as well as improving the participation of CLD children.

Cheng (1996) argued that the key to success in working with CLD clients is both to support the students' transition to the classroom culture and to encourage children to make conscious comparisons and contrasts between home and school cultures. This can best be done, according to Cheng, by encouraging CLD students to bring their experiences with the home culture into the classroom conversation. There are several ways to structure these experiential activities.

Roseberry-McKibbin (2008) suggested using a *multicultural calendar*. Here the clinician or teacher would use the typical classroom theme of holidays and special days to incorporate the experience of the CLD child. Each month, mainstream holidays and holidays from the cultures of the CLD children would be marked on the calendar. Weekly or monthly themes for language activities would revolve around these special days. For example, Thanksgiving might be a theme for November. Here, activities around the traditional American celebration would be combined with discussion of harvest festivals of other cultures. CLD children could be asked to find out how the harvest is celebrated in their culture; to share artifacts, pictures, songs, or dances with the class; and to compare how these holidays are observed. Depending on the developmental level of the class, projects might include making group picture books with labels for objects used in American Thanksgiving and other harvest festival celebrations; making greeting cards to send to family members with pictures, ideas, and phrases typically associated with the mainstream and other

holidays; writing recipes and cooking foods associated with each festival; writing descriptions of how to celebrate each holiday; and so on.

Cheng (2002a) pointed out that *map study* provides another opportunity for incorporating the experience of CLD children in the classroom. Maps can be studied to identify the place of birth of each class member or to follow routes of trips that class members have taken (for CLD children, this can include the route to their country of origin). Students can work in groups to make maps of various places associated with their personal experience, such as their house, home town or village, or home country. Life stories can be written and illustrated with maps relevant to each student's story.

Hyter and Westby (1996) suggested the comparative study of *folktales* as another method to bring the CLD child's experience into school. Here, again depending on the developmental level of the group, age-appropriate folktales from mainstream culture can be read. CLD children can be asked whether they know any similar stories. The clinician or teacher may consult in advance with a librarian about parallel stories from different cultures and obtain books that tell parallel tales. *Little Red Riding Hood* and its Chinese version, *Lon Po Po* (Young, 1989), for example, may be read and compared. Paul Galdone's (1970) traditional retelling of *The Three Little Pigs* can be contrasted with *The Three Little Hawaiian Pigs and the Magic Shark* (Laird, 1981) or *The Three Javelinas* (Lowell, 1992). Various culture's renditions of the Cinderella story, such as *Mufaro's Beautiful Daughters* (Stephoe, 1987), *The Talking Eggs* (San Souci, 1989), *Turkey Girl* (in Verlarde, 1989), and *Yeh-Shen* (Louie, 1982), also can be compared. Many West African folktales (Appiah, 1989; McDermott, 1972), too, have parallels in folktales familiar to mainstream students.

Comparative folklore studies have many advantages. They not only bring students' experience into the classroom, but they also allow metalinguistic focus on different ways of telling stories and support narrative development. Cheng suggested doing activities such as having parents tell stories in the native language, having them translated, and having the CLD child retell the story to the class. Collective stories, in which each member of a group retells a part of a story, also can be used. These group stories can be "published" in class books, with the mainstream and CLD child's version side by side. Discussions of similarities and differences can follow. Related activities might have groups generate yet another version of the same story to write, illustrate, and publish.

Hyter and Westby (1996) also encouraged the use of stories as a way to help children learn to take multiple perspectives. For both mainstream and CLD students these activities help us to learn to try to "walk a mile in another's moccasins," or see how things might look from another's point of view.

Multiple perspective activities include the following:

- Discussing versions of stories told through different characters' eyes, such as *The True Story of the Three Little Pigs by A. Wolf* (told from the wolf's point of view; Scieszka, 1989) or *The Untold Story of Cinderella* (told from the point of view of the stepsisters; Shorto, 1990).
- Discussing controversial topics, such as racial prejudice, through books such as *Roll of Thunder, Hear My Cry* (Taylor, 1975), or *Maniac Magee* (Spinelli, 1990).
- Talking about books that give a first person perspective, such as *Hatchet* (Paulsen, 1987) or *Toning the Sweep* (Johnson, 1993).

Reading and talking about “trickster tales,” stories that involve deception and the need to distinguish between what is intended and what is said; many cultures have tales of traditional tricksters, including Brer Rabbit (Appalachian; Lester, 1990), Anansi the Spider (West African; McDermott, 1972), Raven (Northwest Native American; McDermott, 1993), Iktomi (Plains Native American; Goble, 1990), and Coyote (Southwest Native American; McDermott, 1994).

Cheng (2002a) also suggested the use of cultural “capsules” or “clusters.” These are elements, activities, and events that are unique to a culture. They might include the African-American Kwanza celebration or the Mexican-American use of piñatas. Items related to cultural clusters or capsules can be displayed and discussed, used for vocabulary development, and incorporated into role-playing activities in which children use language forms appropriate for the objects and events. Scripts can be developed ahead of time and rehearsed, so that students can demonstrate their cultural capsules to an audience such as parents or another group of students. Such scripts also will support the students’ development of communicative competence about their own culture.

Mainstream culture capsules also can be included in the intervention program. Here objects and events that may be unfamiliar to the CLD child (such as erasers, rulers, or “lining up”) can be introduced and studied as other culture capsules are. This approach brings home the point that there’s nothing more “right” or “natural” about the school culture than the home culture. What is important is to know the language and behavior that is expected in each. Again, role-playing and previously developed scripts can be useful to help CLD students interact with the culturally specific materials. Teacher-student, storekeeper-customer, doctor-patient, and other familiar roles can be played out to give CLD students additional experience with the language and organization of commonly occurring activities in the mainstream culture.

Cheng (1989) also suggested using the “personal weather report” (Figure 5-5) to help develop vocabulary for emotional expression. Since this is an area in which traditional cultures often differ from our American style of “letting it all hang out,” CLD students may need extra help developing a precise and differentiated lexicon of feelings, beyond *happy*, *sad*, and *mad*. Clinicians can start each session by giving their own personal weather report and asking the students to identify their emotional state on a chart such as the one in Figure 5-5. The label for the chosen emotion can be given, and discussion of the various emotions expressed can be used to compare and contrast the various words and the feelings they represent. Later, figurative uses of words such as “cold” and “warm” to discuss

feelings can be added to the activity. Other figurative uses of such words (“That’s a hot car!”) also might come up. (These activities will also be very helpful for students with autism spectrum disorders).

Scott and Rogers (1996) discussed ways of helping the older CLD student improve writing abilities in the classroom. They emphasized that the writings of CLD students often sacrifice self-expression for the sake of using SAE features. They suggest that students be encouraged to write first for voice and meaning by giving a verbatim transcription of the way the student would convey the message in speech. Through successive editing passes, each attending to only one feature of SAE at a time, the students bridge the gap between their oral speech style and an SAE version. Additional suggestions for SLPs to use in consultation or collaboration with teachers in classrooms with CLD children. These are summarized in Box 5-16.

CONCLUSIONS

We started our discussion of multicultural issues in child language disorders with the reminder that, despite our differences, we are all Americans. Most of us who are SLPs now have ancestors who, at some point, were newcomers to this country and spoke little English, too. Most of us have lost the languages with which our families came to these shores. That has some advantages, like the fact that we can all talk to each other in a rich common tongue that has borrowed elements from many of the languages our families brought here. But the loss of the old languages is sad, too. So many of us are now monolingual, which limits our communication in some ways in this ever-smaller world. As we think about our role in helping new arrivals and those who have been excluded from the mainstream to find their place in the bubbling multicultural mixture that is America, we might do well to remember the pluses and minuses of this historical pattern. We certainly want to help and encourage CLD children and their families to develop proficiency in Standard American English, which will give them the broadest opportunities for scholastic and economic success. But at the same time, we might recall the advantages that being bilingual or bicultural can confer. In working with CLD clients, our challenge is to strike a delicate balance. We must provide the tools of SAE communication that will allow participation in the mainstream culture, but we must do so without confiscating the tools of communication that make the life of the individual rich and integrated and the mosaic of our country increasingly vibrant as new elements continue to be added to its texture.

BOX 5-16 Suggestions for Multicultural Teaching Methods to Support All ELLs in Classrooms

Adapt classroom materials, using culturally familiar names, objects, and events.

Bridge vocabulary development by providing some information and expansion on new English words in the home language.

Build on prior knowledge.

Develop cooperative learning groups; allow groups to work first in home language, then move to English.

Employ peer tutoring and mediation.

Employ role-playing.

Focus on communication in reading and writing.

Integrate culturally based stories.

Provide context and background information.

Provide word maps.

Provide written materials in both English and the first language.

Read aloud to students throughout the elementary grades.

Use a variety of narrative styles (recounts, event casts, etc.).

Use a variety of social organizations for classroom activities; pairs, continuing groups, reshuffling groups.

Incorporate culturally appropriate materials to new curricular topics and themes.

Use dialogue journals in which teacher/clinician responds to, rather than corrects, student writing.

Use language experience stories, in which the teacher writes down students' oral narratives.

Use scripts.

Use semantic webs.

Use social and pragmatic activities.

Use visual and contextual supports by presenting information in spoken, written, and graphic modes.

Use "What I know" charts.

Develop a bicultural approach.

Talk about differences between "home talk" and "school talk."

Encourage extracurricular activities that come from the home culture and that expose children to mainstream culture activities.

Encourage high levels of interaction between CLD and mainstream students, or students with different CLD backgrounds.

Include a strong parental and community involvement component.

STUDY GUIDE

- I. An Introduction to Cultural Diversity
 - A. Define bicultural education.
 - B. Distinguish a language difference from a language disorder.
 - C. Describe some of the factors that contribute to the unique style of communication used by African-Americans.
 - D. List and discuss differences between AAE and Standard American English.
 - E. Define bidialectal.
 - F. Discuss the meaning and importance of code-switching.
 - G. What is meant by limited English proficiency?
 - H. Describe some characteristics of Spanish-influenced English.
 - I. Discuss some features of Native American dialects of English.
 - J. List some features of Asian and Arabic dialects of English.
 - K. Describe the contrasts between high-context and low-context communication. How are these styles associated with CLD children? How do they affect narrative skill?
- II. Assessing Culturally and Linguistically Different Children
 - A. How can language dominance be established? Why is it important to establish it?
 - B. How can interview data be obtained from families of CLD children if the clinician does not speak their language?
 - C. Discuss the appropriate uses of standardized tests with CLD children.
 - D. What are some appropriate modifications to make if standardized tests are not available in the client's dominant language? What are inappropriate modifications? How can the results of these modifications of tests be interpreted properly?
 - E. Describe the Parent-Child Comparative Analysis procedure. Under what circumstances would it be used?
 - F. Discuss the use of speech sample analysis with the CLD child. How can it be done if the clinician does not speak the child's dominant language? How can it be used to differentiate limited English proficiency from a language disorder?
 - G. Explain what the Minimal Competency Core means. Give elements of this core for preschool speakers of AAE.
 - H. How can dynamic assessment be used with CLD children?
 - I. What are the uses of behavioral observation with the CLD child?
 - J. What is ethnographic assessment, and how can it be used in the evaluation of a CLD child?
- III. Language Intervention and the CLD Child
 - A. What are the service delivery options for a CLD child whose dominant language is not English when the clinician is monolingual in English?
 - B. What is the SLP's role with the normally developing child who has LEP or a nonstandard dialect of English?
 - C. Describe a general approach to improving proficiency in SAE for children with LEP or nonstandard dialects. Give several specific examples of activities that might be used in such a program.
 - D. Describe several approaches and activities for making instruction culturally appropriate for CLD children.

Idea Issue Brief

CULTURALLY AND LINGUISTICALLY DIVERSE STUDENTS

What the 2006 IDEA Part B Final Regulations Say:

The 2006 IDEA regulations continue to support appropriate service delivery to culturally and linguistically diverse (CLD) populations. Areas of practice that remain the same include the following:

Assessment and other evaluation materials should not be racially or culturally discriminatory.

Assessment and other evaluation materials are to be provided in the child's native language or other mode of communication unless it is clearly not feasible to do so.

A child must not be determined to be a child with a disability if the determinant factor is lack of appropriate instruction in reading or math, or limited English proficiency.

Parents are entitled to an interpreter at the IEP meeting if needed to ensure that the parents understand the proceedings.

When developing an IEP, in the case of a child with limited English proficiency, the language needs of the child as they relate to their IEP must be considered.

An addition to the 2006 regulations on evaluation procedures (§300.304) requires that assessment and other evaluation materials are administered "in the form most likely to yield accurate information on what the child knows and can do academically, developmentally, and functionally." For CLD students, the "form" in which evaluation procedures are administered will vary. The addition of this new language emphasizes the allowance of variance from standard testing procedures, when necessary, in order to appropriately evaluate a student.

Additionally, the 2006 IDEA regulations made significant steps toward addressing problems with inappropriate identification and disproportionate representation by race and ethnicity of children as children with disabilities. A provision was added requiring states to review ethnicity data in addition to race data to determine the presence of disproportionality (§300.646). In the event that significant disproportionality is determined, the state will not only be required to review and revise policies, procedures, and practices, but also will require the local education agency (LEA) to reserve the maximum amount of funds under §613(f) of the statute to provide early intervening services to children in the LEA, "particularly, but not exclusively" to those in groups that were significantly over-identified. The LEA also will be required to publicly report on the revision of policies, practices, and procedures. These regulations clearly define steps that states must take to address the problem of disproportionality in special education. In particular, mandating that funds under §613 (f) are to be used for early intervening services is an excellent strategy for states with this problem. Research has shown that early intervening strategies assist in reducing the number of inappropriate referrals to special education. Long-term effects of reducing disproportionality using early intervening services

include reduced paperwork as well as a reduced caseload for special education personnel.

Implications for ASHA Members

The statute, IDEA 2004, continues to emphasize the need for appropriate evaluation procedures for CLD students. The 2006 regulations emphasize the allowance of variance from standard testing procedures when necessary to appropriately evaluate a student. Use of nonstandardized testing procedures, such as portfolio assessments or spontaneous language samples, can provide valuable qualitative information on the child's communication skills. When evaluating English language learner (ELL) students, it is important for speech-language pathologists (SLPs) to carefully review the child's language history to determine the language of assessment. If it is determined that the child should be evaluated in a language other than English, the SLP must use all available resources, including interpreters when necessary, to appropriately evaluate the child. In addition, states are facing more stringent repercussions if their school districts are found to have a disproportionate number of CLD students in special education. SLPs will need to ensure that their assessment strategies for these students in particular are appropriate and that they yield the most reliable results.

What ASHA Members Can Do

ASHA members must ensure that their assessments for all students, especially CLD students, are appropriate and yield valid results. SLPs and audiologists must advocate at the state and local levels for identification, assessment, and eligibility policies and procedures for CLD students to assist in eliminating the issues of disproportionality. ASHA members must also advocate for inclusion in the development and provision of early intervening services at www.asha.org/members/slp/schools/prof-consult/RtoI.htm and www.asha.org/about/leadership-projects/multicultural/issues/da/. Research has shown that early intervening strategies assist in reducing the number of inappropriate referrals to special education. Long-term effects of reducing disproportionality using early intervening services include reduced paperwork, as well as a reduced caseload for special education personnel. ASHA members are encouraged to continue developing the knowledge and skills needed to provide culturally and linguistically appropriate services, as well as advocate for resources in order to provide effective services. ASHA has a number of resources on its Web site at www.asha.org/about/leadership-projects/multicultural/ that focus on service delivery to CLD populations. There are also a number of continuing education programs that provide information on best practice for working with ELL students, bilingual populations, and other CLD students.

A Sample of Multicultural Tests and Assessment Materials

Name	Description	Available from
<i>African-American English: Structure and Clinical Implications</i> (Adger, Schilling-Estes, & Wolfram, 2003)	Assesses phonological, grammatical, and pragmatic characteristics of AAE in school-age children. Includes an interactive CD-ROM and manual. Aids understanding of the structure, features, and rules of AAE, in order to work more effectively with children who speak vernacular dialects.	American Speech-Language and Hearing Association 10801 Rockville Pike Rockville, MD 20852
<i>All India Institute of Medical Sciences Test for Auditory Comprehension of Language; All India Institute of Medical Sciences Test of Articulation</i> (S. Bhatnager)	Instrument for diagnosing speech and language disorders in Hindi.	Subhash Bhatnagar Dept. of Communicative Disorders College of Liberal Arts University of Mississippi University, MS 38677 Academic Therapy Publications 20 Commercial Blvd. Novato, CA 94949
<i>Ann Arbor Learning Inventory—Revised (AALI-R)</i> (B. Vitale and W. Bullock) (Available in Spanish)	Assesses skills important to learning, such as visual discrimination, visual memory, auditory discrimination, and auditory memory. Valuable for determining the best form of instruction for a child with disabilities. Offers comprehensive and detailed examination of skills that underlie reading, writing, speaking, listening, and spelling. Grades K-8.	
<i>Assessment Instrument for Multicultural Clients</i> (S. Adler)	A criterion-referenced instrument for examining a broad range of 22 communication behaviors in children with LEP.	In Adler, S. (1991). Assessment of language proficiency in LEP speakers. <i>Language, Speech, and Hearing Services in Schools</i> , 22(2), 12-18.
<i>Assessment of Phonological Processes</i> (B. Hodson) (Available in Spanish)	Identifies error patterns while deemphasizing differences related to dialect variations.	Los Amigos Research Associates 7035 Galewood, Suite D San Diego, CA 97120 CHECpoint System, INC. 1520 N. Waterman Ave. San Bernardino, CA 92404
<i>Basic Inventory of Natural Language</i> (C. Herbert) (Available in Spanish and 31 other languages)	Used for grades K-12. A language sample is scored for fluency, complexity, and average sentence length.	Ber-Sil Co. 3412 Seaglen Dr. Rancho Palos Verdes, CA 90274
<i>Ber-sil Spanish Test</i> (M. Beringer) (Available in Philippine, Tagalog, Ilokano)	Also available in Cantonese, Mandarin, Korean, Persian. Assessment of receptive vocabulary for ages 5-12 years (elementary) and 13-17 years (secondary).	Academic Communication Associates PO Box 566249 Oceanside, CA 92056
<i>Bilingual Classroom Communication Profile</i> (C. Roseberry-McKibbin)	Observational screening tool to help classroom teachers distinguish communication differences from communication disorders.	Academic Communication Associates, Publications Divisions, Dept. 2C PO Box 6044 Oceanside, CA 92056
<i>Bilingual Language Proficiency Questionnaire</i> (L. Mattes and G. Santiago)	Parent interview questionnaire regarding bilingual children's development and use of speech and language. Items listed in both English and Spanish.	Harcourt Assessment 19500 Bulverde Rd. San Antonio, TX 78259
<i>Bilingual Syntax Measures I and II</i> (M. Burt and H. Dulay)	Identifies students' mastery of oral syntactic structures in English and/or Spanish. Pre-K to 12th grade.	Asian-American Bilingual Center 2134 Martin Luther King Jr. Way Berkeley, CA 94709
<i>Bilingual Syntax Measures—Chinese and Tagalog</i> (C. Tsang)	Test of language dominance in Chinese/Tagalog speakers.	

Continued

Name	Description	Available from
<i>The Bilingual Verbal Ability Tests</i> (BVAT) (A.F. Moñoz-Sandoval, J. Cummins, C.G. Alvarado, and M.L. Ruef)	Assesses the following in people 5 years old to adult: Cognitive Ability; Picture Vocabulary, Oral Vocabulary, and Verbal Analogies. Comprised of three subtests from the Woodcock-Johnson—Revised Tests of Cognitive Ability; Picture Vocabulary, Oral Vocabulary, and Verbal Analogies. These three subtests have been translated from English into eighteen languages. The languages available in BVAT are Arabic; Chinese, Simplified; Chinese, Traditional; French; German; Haitian-Creole; Hindi; Hmong; Italian; Japanese; Korean; Navajo; Polish; Portuguese; Russian; Spanish; Turkish; Vietnamese.	Riverside Publishing Company 425 Spring Lake Dr. Itasca, IL 60143
<i>Bilingual Vocabulary Assessment Measure</i> (L. Mattes) (Available in Spanish, French, Italian, Chinese, Vietnamese)	Initial screening for expressive vocabulary.	Academic Communication Associates PO Box 566249 Oceanside, CA 92056
<i>Black English Scoring System</i> (N. Nelson)	Speech sample analysis for Black English speakers; an adaptation of the Developmental Sentence Scoring procedure.	Nelson, N. (1998). In Appendix C of <i>Child language disorders in context</i> . Columbus, OH: Merrill Publishers
<i>Boehm Test of Basic Concepts—3</i> (A. Boehm)	Designed to measure children's mastery of basic concept vocabulary. The test manual and instruments are available in Spanish.	Harcourt Assessment 19500 Bulverde Rd. San Antonio, TX 78259
<i>Bracken Basic Concept Scale—Revised</i> (Bracken, 2006) (Available in Spanish)	Assess 258 basic concepts including color, quantity, shapes. Spanish version for criterion-referenced use only.	Harcourt Assessment 19500 Bulverde Rd. San Antonio, TX 78259
<i>Bracken School Readiness Assessment</i> (B. Bracken)	Assesses the following concepts in children 2:6-7:11 yr: Colors, Letters, Numbers/Counting, Sizes, Comparisons, and Shapes. National norms are provided for English only, but Spanish norms can be developed for local Spanish-speaking population. Includes information on how to develop local norms.	Harcourt Assessment 19500 Bulverde Rd. San Antonio, TX 78259
<i>Brigance Diagnostic Assessment of Basic Skills—Spanish Edition</i> (Brigance)	Constructed using the comprehensive Inventory of Basic Skills (not a direct translation).	Curriculum Associates 153 Rangeway Rd. North Billerica, MA 01862
<i>Brigance Diagnostic Assessment of Basic Skills, Portuguese Edition</i> (H. Groomsman)	Adaptation of the Brigance Test.	Dr. Herbert Groomsman, Director of the Bilingual/Multicultural Special Education Programs Division of Special Education and Rehabilitation Services San Jose State University San Jose, CA 95192
<i>Chinese Oral Proficiency Test</i>	Test of oral comprehension and word association in Chinese and English for children in grades K–6.	The National Hispanic University 255 East 14th St. Oakland, CA 94606
<i>Chinese Test, Chinese Literature and Cultural Test, Chinese Bilingual Test</i> (Metcalf)	Test and materials for use with speakers of Chinese.	Chinese Bilingual Project San Francisco Unified School District San Francisco, CA 94102
<i>Clinical Evaluation of Language Fundamentals—4</i> (CELF-4; Semel, Wiig, & Secord) (Available in Spanish)	CELF-4 Spanish has been enhanced to better address the needs of clinicians who serve Spanish-speaking children and young adults. CELF-4 Spanish was developed specifically for Spanish speakers living in the U.S. as a parallel test to the English edition of CELF-4. It is <i>not</i> a translation of the English edition of CELF-4. Test items incorporate grammatical forms appropriate for Spanish speakers and themes familiar to Spanish speaking students.	Harcourt Assessment 19500 Bulverde Rd. San Antonio, TX 78259
<i>Compton Speech and Language Screening Evaluation: Spanish Adaptation of Revised Edition</i> (A. Compton and M. Kline)	Measure of speech and language in Spanish-speaking children, ages 3-6 yr.	Carousel House PO Box 4480 San Francisco, CA 94101

Name	Description	Available from
<i>Denver Developmental Screening Test II—Spanish</i> (W. Frankenburg et al.)	Determines whether a child's development is within normal range. Identifies children ages 1 mo to 6 yr likely to have motor, social, and/or language delays.	Denver Developmental Materials PO Box 371075 Denver, CO 80237
<i>Developing Skills Checklist (DSC)</i> (C.K. Tanner) (Available in Spanish)	Comprehensive checklist that evaluates a wide range of skills in children in pre-K and kindergarten. Measures language, mathematical concepts and operations, fine and gross motor skills, visual memory, auditory skills, printing, and writing.	CTB/McGraw-Hill PO Box 150 Monterey, CA 93942
<i>Developmental Assessment of Spanish Grammar</i> (A. Toronto)	A language-analysis procedure for Spanish-speaking children; an adaptation from the Developmental Sentence Scoring procedure in English.	In Toronto, A.S. (1976). Developmental assessment of Spanish grammar. <i>Journal of Speech and Hearing Disorders</i> , 41, 150-171.
<i>Diagnostic Evaluation of Language Variation</i> (DELV; Seymour, Roeper, & de Villiers, 2005)	A diagnostic instrument to assess the status of four language domains (i.e., Phonological, Syntactic, Semantic, and Pragmatic) in children ages 4:0–9:11 with assessment that is unbiased for AAE speakers.	The Psychological Corporation 19500 Bulverde Road San Antonio, TX 78259
<i>Developmental Indicators for the Assessment of Learning—3 (DIAL-3; C. Mardell-Czudnowski and D. Goldenberg)</i> (Available in Spanish)	Screens development in motor, concept, language, self-help, and social function areas. Identifies children ages 3-7 yr who are likely to need special services.	American Guidance Service 4201 Woodland Rd. Circle Pines, MN 55014
<i>Developmental Programming for Infants and Young Children</i> (D. Schafer, M. Moersch, and D. D'Eugenio) (Available in Spanish)	Assesses function and facilitates development of children, ages birth to 6 yr, in six areas: perceptual/fine motor, cognition, language, social/emotional, self-care, and gross motor.	University of Michigan Press PO Box 1104 Ann Arbor, MI 48106
<i>Diagnostic Evaluation of Language Variation</i> (DELV-Criterion Referenced) (H.N. Seymour, T.W. Roeper, and J. de Villiers)	Assesses comprehensive speech and language, including pragmatics, syntax, semantics, and phonology in 4- to 9-yr-olds. Helps distinguish language differences from language disorders. Criterion-referenced scoring.	Harcourt Assessment 19500 Bulverde Rd. San Antonio, TX 78259
<i>Dos Amigos Verbal Language Scale</i> (D. Critchlow)	Assesses language functioning in English and Spanish students between the ages of 5 and 13 yr.	United Educational Service Box 605 East Aurora, NY 14052
<i>Early Literacy Skills Assessment</i> (ELSA; DeBruin Parecki, 2007)	ELSA is a criterion-referenced test for use with children ages 3:0–5:11. The test is relatively short (15-20 min) and is designed to assess early literacy skills believed to be associated with later reading achievement. Spanish Version available.	High/Scope Educational Research Foundation 600 North River St. Ypsilanti, MI 48198
<i>El CIRCO Assessment Series</i>	Assesses comprehension of mathematical concepts and basic linguistic structures in Spanish and English. Also screens facility in Spanish before administration. Developed for Spanish-speaking children from Mexican-American, Puerto Rican, and Cuban backgrounds.	CTB/McGraw-Hill Del Monte Research Park Monterey, CA 93940
<i>Evaluating Communicative Competence</i> (C. Simon) (Available in French-Canadian)	Ages 10 years and older. Uses a series of 21 receptive and expressive language tasks to document a profile of functional communication proficiency.	Thinking Publications 424 Galloway St. Eau Claire, WI 54703
<i>Expressive and Receptive One-Word Picture Vocabulary Test—Spanish-Bilingual Edition</i> (R. Brownell, Ed.)	Offers an assessment of expressive vocabularies of individuals who are bilingual in Spanish and English. By permitting examinees to respond in both languages, this test assesses total acquired vocabulary. The tests are co-normed on a national sample of Spanish-bilingual individuals ages 4 years, 0 months through 12 years, 11 months. Record forms include acceptable responses and stimulus words in both languages.	Academic Therapy Publications 20 Commercial Blvd. Novato, CA 94949
<i>Get Ready to Read! Revised</i> (Whitehurst & Lonigan)	A screening tool to evaluate readiness for learning to read and write. Specifically developed for preschoolers, the test has been evaluated for its reliability, factor structure, relationship with other literacy assessments, and consistency across children from low- and middle income backgrounds. Backed by the National Center for Learning Disabilities, the instrument has been field-tested in early childhood programs. In Spanish.	Pearson Assessments 19500 Bulverde Road San Antonio, TX 78259-3701

Continued

Name	Description	Available from
<i>Stanford English Language Proficiency Test</i> (Harcourt Assessment)	A criterion-referenced assessment of English language proficiency designed for English language learners in Grades K–12. The test is based on the 1997 version of the standards of the Teachers of English to Speakers of Other Languages (TESOL) and on individual state standards for English as a Second Language (ESL). Its primary purpose is to determine whether the student possesses the English language skills necessary to function in instructional settings in English.	Harcourt Assessment, Inc. 19500 Bulverde Road San Antonio, TX 78259-3701
<i>IPT 2004 Language Proficiency Tests</i>	Grades pre-K–12, available in English and Spanish. Assesses oral, reading, and writing proficiency. Scoring software available.	Ballard and Tighe, Publishers P.O. Box 219 Brea, CA 92821-0219
<i>Language Assessment Scales—Oral</i> (LASA-O) (S. Duncan and E. deAvila)	Assesses oral language proficiency in English and Spanish. Available at three levels: Pre-LAS for preschoolers, LAS I for grades K-5, and LAS II for grades 6-12.	CTB/McGraw-Hill Del Monte Research Park Monterey, CA 93940
<i>Language Experience and Proficiency Questionnaire</i> (LEAP-Q; Marian, V., Blumenfrel, H., & Kaushanskaya)	Designed to assess bilingual individuals' linguistic profiles. It is used to assess bilingual experience and proficiency profiles in first and second languages and is a self-report questionnaire. It can be used with adolescent and adult bilinguals and multilinguals.	Journal of Speech, Language, and Hearing Research, 50, 940-67.
<i>Lindamood Auditory Conceptualization Test—Spanish Version</i> (C. Lindamood and P.C. Lindamood)	Criterion-referenced test that measures phonological awareness and segmentation skills. Examiner's cue sheet for testing Spanish-speaking subjects.	DLM Teaching Resources 1 DLM Park Allen, TX 75002
<i>Logramos</i> (Riverside Publishing)	Assesses reading, language, and math in K-12th grades. Standardized test designed to measure the academic progress of Spanish-speaking students. Depending on grade level, can require up to 8 subtests to be administered.	Riverside Publishing Company 425 Spring Lake Dr. Itasca, IL 60143
<i>Look Listen and Tell: A Language Screening Instrument for Indian Children</i>	Language screening device for Native American children ages 3-7 yr. Can be used by child-care workers without training in speech-language pathology. It is not standardized.	Southwest Communication Resources, Inc. PO Box 788 Bernalillo, NM 87004
<i>MacArthur Inventarios del Desarrollo de Habilidades Comunicativas</i> (Inventarios) (Translated and adapted by Jackson-Maldonado, Bates, & Thal, 2005)	Assesses expressive and receptive vocabulary sizes and early grammatical production in infants 8-30 mo. Parent-report instrument. Reports good validity when compared with direct observation measures. The CDIs (English version of instrument) were normed on approximately 1800 children in three locations, and the Inventarios were normed on more than 2000 children.	Paul H. Brookes P.O. Box 10624 Baltimore, MD 21285-0624
<i>Medida de Sintaxis Bilingue, I and II</i> (Bilingual Syntax Measure, I and II [BSMJ]) (M. Burt, H. Dulay, and E. Chavez)	CDIs are also available in several other languages. Uses pictures and questions to elicit language samples to be analyzed for proficiency levels in English and Spanish. BSM is available at two levels: BSM I for grades K-2, BSM II for grades 3-12.	Harcourt Assessment 19500 Bulverde Rd. San Antonio, TX 78259
<i>Medida Espanola de Articulacion</i> (Spanish Articulation Measure) (M. Aldrich-Mason, B. Figueroa-Smith, and M. Martinez-Hinshaw)	Assesses early development of phonemes in Spanish.	Martha Lerma San Ysidro School District 4350 Otay Mesa Rd. San Ysidro, CA 92073
<i>Multicultural Vocabulary Test</i> (G. Trudeau)	Test expressive vocabulary of body parts in any language. Yields age equivalents 3-13 yr.	Los Amigos Research Associates 7035 Galewood, Suite D San Diego, CA 92120
<i>The Oral Language Acquisition Inventory & The Oracy Instructional Guide</i> (OLAI; L. Gentile)	Provides information about the most common language structures children use expressively and shows clinicians to how elicit meaningful conversation and develop prompts that expand and refine language with English-language learners and children who could benefit from language instruction.	Pearson Assessments 19500 Bulverde Road San Antonio, TX 78259-3701
<i>PAL Oral Language Dominance Measure</i> (R. Apodaca)	Picture descriptions yield information for determining oral language proficiency in English or Spanish.	Susie Snyder El Paso Public Schools PO Box 2100 El Paso, TX 79998

Name	Description	Available from
<i>Parents' Observations of Infants and Toddlers</i> . (POINT; Mardell, & Goldenberg)	To be completed by one or two parents/guardians and/or one or two caregivers; Spanish version available; standardized in Spanish and English. POINT is a 128-item reporting tool for parents and primary caregivers of children ages 2-36 mo. It is targeted to chart normal developmental milestones and to screen for current or potential problems in cognitive, physical, social-emotional, language, or school readiness development.	Master Publishing, Inc. 6125 West Howard St. Niles, IL 60714-3401
<i>Preschool Language Assessment Instrument: The Language of Learning in Practice</i> —Spanish Language Edition (M. Blank, S. Rose, and L. Berlin)	Assesses 3- to 6-year-olds' ability to name, imitate, sequence, match, define, predict, remember, and describe. Provides information on how children handle language demands of the classroom and how to effect appropriate programming.	The Speech Bin 213 Clarksville Rd. PO Box 218 Princeton Junction, NJ 08550-0218
<i>Preschool Language Scale</i> (PLS-5) (I. Zimmerman, V. Steiner, and R. Pond) (Available in Spanish)	Diagnostic measure of receptive and expressive language. Subtests measure grammar, vocabulary, memory, attention span, temporal and spatial relations, and self-image. Record forms are available in English and Spanish (Mexican-American).	The Psychological Corporation PO Box 9954 San Antonio, TX 78204
<i>Prueba Del Desarrollo Initial Del Lenguaje</i> (W. Hresko, D. Reid, and D. Hammill) (Tests speakers of Spanish)	Measures spoken language, expressive and receptive syntax, and semantics in Spanish.	Pro-Ed, Inc. 8700 Shoal Creek Blvd. Austin, TX 78757-6897
<i>Receptive One-Word Picture Vocabulary Test</i> —Spanish-Bilingual Edition (R. Brownell, Ed.)	Offers an assessment of receptive vocabularies of individuals who are bilingual in Spanish and English. By permitting examinees to respond in both languages, this test assesses total acquired vocabulary. The test is co-normed on a national sample of Spanish-bilingual individuals ages 4:0-12:11. Record forms include acceptable responses and stimulus words in both languages.	Academic Therapy Publications 20 Commercial Blvd. Novato, CA 94949
<i>Scales of Independent Behavior—Revised</i> (SIB-R) (R. Buininks, R. Woodcock, R. Weatherman, and B. Hill) (Available in Spanish)	Assesses four adaptive behavior clusters: motor skills, social and communication skills, personal living skills, and community living skills. Ages birth to adult.	Riverside Publishing Company 425 Spring Lake Dr. Itasca, IL 60143
<i>Screening Kit of Language Development</i> (SKOLD) (L. Bliss and D. Allen)	Assesses preschool language development and aids in early identification of language disorders/delays in speakers of Standard English and AAE.	Slosson Educational Publications PO Box 280 East Aurora, NY 14052
<i>Screening Test of Spanish Grammar</i> (A. Toronto)	Used to identify Spanish-speaking children with grammatical difficulties who need further evaluation.	Northwestern University Press 1735 Benson Ave. Evanston, IL 60201
<i>Spanish Articulation Measures—Revised Edition</i> (L. Mettes)	A criterion-referenced measure using spontaneous and elicited tasks to assess speech sound production and use of phonological processes. For school-age Spanish-speaking children.	Academic Communication Associates Publications Division Department 2C PO Box 6044 Oceanside, CA 92056
<i>Spanish Assessment of Basic Education—Second Edition</i> (SABE-2) (CTB Macmillan/McGraw Hill)	Grades 1-8. Norm-referenced measure of Word Attack, Vocabulary, Reading Comprehension, Mechanics, Expression, Mathematics Computation, Mathematics Concepts and Applications, Total Reading, Total Mathematics, Total Battery, Spelling, Study Skills.	CTB Macmillan/McGraw-Hill 2500 Garden Rd. Monterey, CA 93940
<i>Spanish Language Assessment Procedures: A Communication Skills Inventory—Third Edition</i> (Revised) (L. Mattes)	Criterion-referenced measures for assessing vocabulary development, speech sound production, sentence structure, listening, pragmatics, and other aspects of a child's communication.	Academic Communication Associates Publications Division Department 2C PO Box 6044 Oceanside, CA 92056
<i>Spanish Oral Language Screening Instrument</i>	A screening instrument for examining language skills in Spanish-speaking children; grades K-6.	The National Hispanic University 255 E. 14th St. Oakland, CA 94606
<i>Spanish Test for Assessing Morphologic Production</i> (STAMP; T. Nugent, K. Shipley, and D. Provencio)	Assesses production of plurals, verb endings, and other structures as children complete sentences related to the action in pictures. Ages 5-11 yr.	Academic Communication Associates P.O. Box 566249 Oceanside, CA 92056

Continued

Name	Description	Available from
<i>Spotting Language Problems: Pragmatic Criteria for Language Screening</i> (J. Damico and J. Oller)	A language-screening instrument with a pragmatic focus; for use with English-speaking, bilingual, or LEP children. In-service training suggestions for teachers also are provided.	Los Amigos Research Associates 7035 Galewood, Suite D San Diego, CA 92120
<i>Structured Photographic Expressive Language Test—II and P</i> (E. Werner and J. Krescheck) (Available in Spanish)	Test of expressive language for Standard English or African-American English speakers. Available for preschoolers or elementary age children. Spanish version also available.	Janelle Publications PO Box 12 Sandwich, IL 60548
<i>Test de Vocabulario en Imagenes Peabody</i> (L. Dunn, D. Lugo, E. Padilla, and L. Dunn)	Contains items from PPVT-R, selected for universality and appropriateness is Spanish.	American Guidance Service 4201 Woodland Rd. Circle Pines, MN 55014
<i>Test for Auditory Comprehension of Language: English and Spanish Forms—3</i> (E. Carrow-Woolfolk)	Designed for use with children aged 3-6 yr to measure receptive language in English or Spanish.	Pro-Ed, Inc. 8700 Shoal Creek Blvd. Austin, TX 78757-6897
<i>Test of Auditory Perceptual Skills—Revised</i> (TAPS-R; M. Gardner) (Available in Spanish)	For children who have diagnoses of auditory perceptual difficulties, imperceptions of auditory modality, language problems, and/or learning problems.	Academic Therapy Publications 20 Commercial Blvd. Novato, CA 94949
<i>Test of Auditory Processing Skills, Third Edition, Spanish-Bilingual Edition</i> (TAPS-3 SBE; Martin, N., 2009)	An individually administered test of auditory skills used in academic and everyday activities. The test was normed on Spanish-bilingual children from 5 years through 18 years of age. TAPS-3: SBE is intended to be used as part of a battery of tests to determine how children use and understand what they hear. Subtests: auditory figure-ground; word discrimination; phonological segmentation; phonological blending; number memory forward; number memory reversed; word memory; sentence memory; auditory comprehension; auditory reasoning.	Academic Therapy Publications, 20 Commercial Boulevard Novato, CA 94949
<i>Test of Auditory Reasoning and Processing Skills</i> (TARPS; M. Gardner) (Available in Spanish)	Age range 5-14 years. Assesses ability to think, understand, reason, and make sense out of what a child hears. Evaluates how children understand, interpret (process), draw conclusions, and make inferences from auditory information.	Slosson Educational Publications PO Box 280 East Aurora, NY 14052
<i>Test of Phonological Awareness in Spanish</i> (TPAS; C.A. Riccio, B. Imhoff, J. E. Hasbrouck, and G.N. Davis)	Measures phonological awareness skills in Spanish-speaking children ages 4-10:11 yr. Normed on over 1000 Spanish-speaking children. Internal consistency reliabilities from 0.87 to 0.98, test-retest reliability for composite scores are above 0.80.	Pro-Ed, Inc. 8700 Shoal Creek Blvd. Austin, TX 78757-6897
<i>Test of Early Language Development—Third Edition: Spanish Version</i> (TELD-3:S; Ramosm Ramos, Hresko, Reid, & Hammill, 2007)	Based on a translation and adaptation of the Test of Early Language Development—Third Edition (TELD-3; Hresko, Reid, & Hammill, 1999). It evaluates the early language development of Spanish-speaking young children (i.e., monolingual or Spanish-dominant) between the ages of 2 yr and 7:11 yr.	Pro-Ed, Inc. 8700 Shoal Creek Blvd. Austin, TX 78757-6897
<i>Vineland Adaptive Behavior Scales—II</i> (S. Sparrow, D. Balla, and D. Cicchetti) (Available in Spanish—interview forms and reports to parents/caregivers only)	Assesses performance of daily activities required for personal and social self-sufficiency. Ages birth-90 yr.	American Guidance Service 4201 Woodland Rd. Circle Pines, MN 55014
<i>Woodcock-Munoz Language Survey—Revised</i> (R. Woodcock and A. Muñoz-Sandmal) (Available in Spanish)	Measures cognitive, academic, and language proficiency. Assesses picture vocabulary, verbal analogies, letter-word identification, and dictation as measures of oral language, reading, and writing domains.	Riverside Publishing Company 425 Spring Lake Dr. Itasca, IL 60143
<i>Woodcock Language Proficiency Battery—Revised</i> (R. Woodcock) (English and Spanish forms available)	Measure of oral and written language skills, receptive and expressive semantics.	Riverside Publishing Company 425 Spring Lake Dr. Itasca, IL 60143
<i>Zuni Articulation Test</i>	Alphabet book adapted for use as a stimulus for articulation testing. Picture and word stimuli for sounds in initial and medial positions are provided. Several pictures are presented for each sound. Training in test administration procedures is required.	Zuni Public School District Speech and Language Therapy Program PO Box Drawer A Zuni, NM 87327

Name	Description	Available from
<i>Zuni Language Screening Instrument</i>	Assesses language proficiency in the Zuni language for children in grades K–12. Both receptive and expressive language are measured, and a language sample can be obtained. Instructions have been taped in Zuni; age-appropriate language samples obtained from the test's picture sequence stories are provided for comparison with assessment data collected. Training is required in test administration procedures.	Zuni Public School District Speech and Language Therapy Program PO Box Drawer A Zuni, NM 87327

CHAPTER

6

Assessment and Intervention in the Prelinguistic Period

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Discuss the principles of family-centered practice for infants and newborns.
2. Describe the elements required for service plans for prelinguistic clients.
3. List risk factors for communication disorders in infants.
4. Discuss the principles of assessment and intervention for high-risk infants and their families in the newborn intensive care nursery.
5. Describe methods for assessment and intervention for preintentional infants and their families: 1 to 8 months.
6. Describe assessment and intervention for infants at prelinguistic stages of communication: 9 to 18 months.
7. Discuss the issues relevant to communication programming for older prelinguistic clients.
8. Describe assessment and intervention strategies for prelinguistic children with autism spectrum disorders.

Janice was born with Down syndrome (DS) 8 weeks before her due date. She weighed less than 4 pounds and had to spend 1 month in the hospital before she was able to go home. She developed respiratory distress syndrome and needed to be intubated and placed on a ventilator for 2 weeks. Her mother had to travel back and forth every day from her home outside the city to visit her, and she had to find someone to care for her other two preschoolers each

time. She had arranged for a 6-week maternity leave at her job; as the end of the leave grew nearer, she became more and more worried that she would lose her position if she couldn't go back on time. She was able to get another 6 weeks to allow her to get the baby settled at home, but she didn't see how she could manage to go back to work even then. Janice's father worked in a glass factory and was working double shifts to keep up with the family's co-pays on the doctor bills. He hardly saw Janice when she was in the hospital.

When she came home, Janice weighed just 5 pounds. The tube had been removed and she was able to breathe without a ventilator, but she seemed so tiny and fragile and had been so sick that her mother was frightened to be away from the medical setting, even though she was glad to be able to stop running back and forth between there and home. Janice had trouble sucking; feeding her took close to 1 hour, and even so she needed a bottle every 3 hours or so. Her mother was frazzled with trying to get enough milk into Janice to keep her growing and still pay some attention to the other two children. She found she was hardly doing anything with Janice but giving her bottles and trying desperately to get other things done in the short time she had between feedings. And always in the back of her mind was the question: Janice was going to be retarded—how could this have happened? Could she love a child who was so different? How would she and her family manage to raise a handicapped child? Would she grow like the other children and learn to walk and talk and play? Her husband was anxious about the expenses at the hospital and resentful that Janice's mother was so exhausted that she could barely talk to him the few hours a day he was home, let alone cook a meal or get the laundry done.

FAMILY-CENTERED PRACTICE

Janice is one kind of baby who is at risk for language and communication disorders. There are many kinds of risk (see Paul & Roth, 2011); what they have in common is their impact, not only on the infant but also on the family. The burden of caring for and fostering the development of infants at risk for communication disorders falls on their families, who may already be experiencing a great deal of stress. Even caring for a healthy newborn is hard work. Imagine how much harder that work becomes when it is done in the context of constant anxiety about the infant's well-being and future. When we deal with infants at risk for communication disorders we are dealing with the family in which the infant finds a home. Although this is true for every client we see, it is especially true for the very youngest of our charges, who depend on the adults in their environment for every aspect of their existence. When thinking about the needs of the high-risk infant, we need to think about the needs of the family, too, to provide that infant with the best environment for growth and development. A variety of resources are available to help clinicians develop family-centered practice skills. Bruns and Steeples (2001) and Crais (1991), for example, made some suggestions for strategies to be used in family-centered practice. These strategies are summarized in [Appendix 6-1](#). Additional resources include Andrews and Andrews (1990), Crais and Calculator (1998), Dinnebeil and Hale (2003), Donahue-Kilburg (1992), Griffin (2006), and McWilliams (1992).

SERVICE PLANS FOR PRELINGUISTIC CLIENTS

Recent changes in federal policy have helped to move clinicians in the direction of family-centered practice. Public Law 99-457, part of the Education of the Handicapped Act Amendments of 1986 (Part H), was the landmark legislation that established a discretionary program to help states set up early identification and intervention services for infants, toddlers, and their families. These were incorporated into the 1997 reauthorization of the Individuals with Disabilities Education Act (IDEA; PL 105-17) and into the 2004 reauthorization. This legislation establishes the requirement for an Individual Family Service Plan (IFSP) for children in the birth-to-3 age range that must include services needed not only to maximize the development of the child but also to optimize the family's capacity to address the child's special needs. The IFSP is similar to an Individual Education Program for a school-aged child, but instead of focusing on the child alone, the IFSP focuses on the child within the context of the family. In addition, the IFSP is a plan for comprehensive services to support the child's development in the context of the family; the IEP is focused exclusively on educational programming. The IFSP should include information about the family's resources, priorities, and concerns for the child's development. The plan, then, also may include some services for the family, such as skilled child care to provide respite for them, or other social services that the family feels are necessary to help them cope with the stress of raising a handicapped child.

The elements that are required by law to be included within an IFSP, according to the 2004 reauthorization of IDEA, include the following:

1. Information about the child's present level of physical, cognitive, social, emotional, communicative, and adaptive development, based on objective criteria.
2. A statement of the family's resources, priorities, and concerns related to enhancing the development of the child, with the concurrence of the family.
3. A statement of the major outcomes expected to be achieved for the child and family, and the criteria, procedures, and timelines used to determine progress and whether modifications or revisions of the outcomes or services are necessary.
4. A statement of the specific early intervention services necessary to meet the needs of the child and the family to achieve the specified outcomes including (1) the frequency, intensity, and method of delivering the services and (2) the environments in which early intervention services will be provided and a justification of the extent, if any, to which the services will not be provided in a natural environment, the location of the services, and the payment arrangements, if any.
5. A list of other services such as (1) medical and other services that the child needs and (2) the funding sources to be used in paying for those services or the steps that will be taken to secure those services through public or private sources.
6. Projected dates for initiation of the services as soon as possible after the IFSP meeting and anticipated duration of those services.
7. The name and discipline of the service coordinator who will be responsible for the implementation of the IFSP and coordination with other agencies and persons.
8. A plan for transition to preschool services.

Johnson, McGonigel, and Kaufmann (1989); Nelson and Hyter (2001); and Yaoying (2008) provided guidelines for developing IFSPs. They reported that no official form or format has been approved for these plans in order to give teams the freedom to develop whatever works best for an individual family. Some teams use only handwritten IFSPs to allow for immediate recording and to keep them dynamic and easy to revise. Other teams create model formats that can be adapted to individual families by the team members. Some teams now use hand-held or tablet electronic devices, such as the iPhone or iPad to create IFSPs from templates the team designs (e.g., Thao & Wu, 2006; Wu et al., 2007). An example of one possible format for an IFSP appears in [Appendix 6-2](#).

For some infants who are identified at birth as high risk, an IFSP may be implemented very soon after the baby leaves the hospital. For others, a decision may be made to wait and watch the child's development before instituting a plan. The decision to provide services also depends on the particular family and the team of professionals with whom they work. A single, teenage, drug-abusing mother living in poverty may herself feel, and be considered by the team of professionals, to be in need of supportive services for her premature infant when she leaves the hospital for the first time. On the other hand, a middle-class married woman in her 20s, with a mother living nearby who has offered to help, may be able to cope on her own for a time, as long as follow-up assessment is provided to ensure that the infant is developing.

Other children in the prelinguistic stage of development may be identified some time after birth. Some will be discovered through Child Find and other screening programs. Child Find programs are mandated by the IDEA and are targeted at early identification of children with special needs who might not otherwise come to the attention of agencies who could serve them. These children may have conditions that are not identified at birth, nonspecific forms of intellectual disability that have no obvious physical signs, or autism

that does not become apparent until later when communication skills emerge in normal development. As Nelson (1998) pointed out, finding these children is not as easy as it sounds; even many professionals are unaware of the need for and appropriateness of intervention in this very early part of life. Public education of both parents and professionals is an important component of Child Find efforts, in order to increase the likelihood that children will be referred for diagnostic services. Multiple observations are often needed to establish special needs in early development, since infant behavior changes so dramatically during the first year of life.

Other children functioning at prelinguistic levels of development are those with severe to profound handicaps, who will be considerably older than the at-risk infants whom we've been discussing. These clients may have been identified at birth or early in life and may have received intervention for some time. They will, though, continue to have needs related to the development of basic preverbal communication skills. We'll talk about services for these clients in the last section of this chapter.

Many of the instruments used for screening and diagnostic assessment in the prelinguistic period are listed in [Appendix 6-3](#). Using instruments with strong psychometric properties is just as important in early assessment as it is for any client, for all the reasons we talked about in Chapter 2. Clinicians choosing assessment instruments for prelinguistic children should apply all the same psychometric standards in making this judgment that would be used in selecting tests for older children. Similarly, we will always need to supplement standardized instruments with more flexible and ecologically valid measures. Crais (1995, 2011) and the American Speech-Language and Hearing Association (ASHA, 2008) discussed the importance of including caregivers as significant partners in the assessment, and using culturally sensitive procedures and naturalistic observations of play and other daily routines within the assessment process. These measures, which go beyond traditional instruments, will always contribute important information to the data that we collect.

When providing services to high-risk infants and their families, the language pathologist will be an integral part of the team of professionals developing the IFSP. Language disorders are the most common developmental problem that presents in the preschool period (ASHA, 2008), so any infant at risk for a developmental disorder in general is at risk for language deficits in particular. These babies do not have communication disorders yet; work with high-risk infants and their families is a preventive form of intervention. We've talked about primary and secondary prevention as important aspects of the role of the speech-language pathologist (SLP). When working with high-risk infants, primary and secondary prevention are the predominant goals. We hope that by working with these families to enhance the baby's communicative environment, we can ward off some of the deficits for which they may be at risk or minimize the extent of these deficits.

Many high-risk infants present with feeding problems, hearing losses, and neurological and behavioral difficulties that can influence communication development. For these reasons and to prevent later deficits, SLPs are very likely to be called upon to participate in the planning and delivery of services for the high-risk infant. Bear in mind that this enterprise must always be a team effort that involves professionals from a variety of disciplines and viewpoints, as well as the infant's family. The SLP needs to be ready to lend expertise on communication acquisition and its disorders in a collaborative spirit.

RISK FACTORS FOR COMMUNICATION DISORDERS IN INFANTS

Who are high-risk infants? Any condition that places a child's general development in jeopardy also constitutes a risk for language development. The March of Dimes (2003) estimates that 12% of newborns can be considered as high risk. In this chapter, we'll discuss some of the conditions that place an infant at risk and talk about strategies for serving at-risk infants and their families at three different developmental stages: the newborn period, the pre-intentional period from a developmental level of 1 to 8 months, and the period of prelinguistic communication from a developmental age of 9 to 18 months. First, let's look at some of the conditions that place an infant at risk for communication disorders.

Prenatal Factors

As we've discussed, anything that could lead to a developmental disorder can constitute a risk for the development of communication in infants. Certain prenatal factors place an infant at risk. These factors include maternal consumption of excessive alcohol, which may result in fetal alcohol syndrome—a pattern of deficits including small size, developmental delay, and facial abnormalities—as well as abuse of other drugs, which often occurs in conjunction with alcohol abuse. Exposure to environmental toxins such as lead, mercury, and other heavy metals, and in utero infections such as rubella, cytomegalovirus (CMV), and toxoplasmosis also place a child at risk.

Prematurity and Low Birth Weight

Prematurity is defined as birth prior to 37 weeks' gestation, with low birth weight. Low birth weight is defined as less than 2500 grams, or 5.5 pounds; very low birth weight (VLBW) is considered less than 1500 grams, or 3.3 pounds. Seriously premature birth and its consequent low birth weight can constitute both medical and developmental risks; low birth weights have been found to be associated with increased risk of developmental delay (Fanaroff, Hack, & Walsh, 2003; Gargus et al., 2009; Taylor, Burack, Holding, Lekine, & Hack, 2002). Premature infants are also more susceptible to a range of illnesses and conditions that produce developmental disabilities, such as respiratory distress syndrome, apnea (interrupted breathing), bradycardia (low heart rate), necrotizing enterocolitis (a serious intestinal disorder), and intracranial hemorrhage (Bernbaum & Batshaw, 2007). Respiratory distress in premature babies can sometimes lead to the need for intubation and the use of ventilators to aid breathing, as it did in Janice's case. This can, in a minority of instances, lead to *bronchopulmonary dysplasia*, a thickening of the immature lung wall that makes oxygen exchange difficult (Rais-Bahrami, Short, & Batshaw, 2002). For children suffering from this condition, long-term tracheostomy may be necessary, which can affect both speech and language development (Mathew, Worth, & Mhanna, 2010; McGowan, Bleile, Fus, & Barnas, 1993; Woodnorth, 2004). Furthermore, treatment of the premature child may have negative consequences, even though it is necessary to save the child's life. Newborn intensive care nurseries can be noisy and overstimulating (Aucott, Donohue, Atkins, & Allen, 2002); in the past, some infants even suffered noise-induced hearing losses (Kellman, 2002). The communicative environment also presents risks. Infants there undergo painful procedures such as suctioning

and intubation, which can cause oral defensiveness or aversion, and trauma or tissue damage to the larynx (Comrie & Helm, 1997). Parents are unable to spend as much time interacting with very small newborns as parents of larger babies, because of the infants' need for hospitalization and medical treatment. Furthermore, the parents' perception of the baby as weak and sick may result in less willingness to hold, handle, and play with the child.

The first hurdle that the premature infant faces is to survive the premature birth. The smaller and younger the baby is at birth, the greater the chances for mortality. Survival rates for very small (500 to 1500 grams) or very young (more than 10 weeks' preterm) babies are increasing, though, because of advances in intensive care for newborns. As recently as 1960, only about 50% of these babies survived, whereas by 2002 survival rates were 55% for infants weighing 501 to 750 grams, 88% for 751 to 1000, 94% for 1001 to 1250, and 96% for 1251 to 1500 (Fanaroff et al., 2007). As more of these tiny babies—who would not have lived 50 years ago—mature, the rate of developmental delays seen in the population of children with a history of prematurity also may increase. Current estimates place the risk of developmental delays near 50% for all infants born prematurely (Rosetti, 2001; Woodward et al., 2006), and, on average, full-term infants have significantly higher cognitive scores compared with children who were born preterm (Bhutta, Cleves, Casey, Cradock, & Anand, 2002). The good news is that early intervention clearly makes a difference. Blair and Ramey (1997); Bleile and Miller (1993); and Rauh, Achenbach, Nurcombe, Howell, and Teti (1988) reported that low-birth-weight babies who receive intervention consistently show benefits over untreated groups in terms of IQ. Spittle et al. (2007) reported that preterm infants treated after discharge did better than untreated peers through preschool age, although longer term follow-up suggests that children with birth weights above 2000 grams derive the most long-term benefit from early intervention (McCormick et al., 2006). Ment et al. (2003) showed that early intervention had its greatest effect on infants whose mothers had less than a high school education. These findings suggest that a relatively small investment in intervention can have important effects for children who have risks associated with prematurity and low birth weight.

Genetic and Congenital Disorders

Many congenital and inherited disorders also place children at risk for developing language and cognitive deficits. Inborn errors of metabolism, such as Hurler syndrome, Hunter's syndrome, and Morquio syndrome, are examples. Craniofacial disorders, which have adverse effects on the morphology of the auditory mechanism, as well as congenital forms of deafness, put a child at risk because information from the auditory channel is lost. A variety of chromosome abnormalities also can influence communicative development. These include DS (trisomy 21; three members of chromosome 21, instead of the normal two) and Cri du Chat syndrome (5p-, absence of the short arm of the fifth chromosome). Disorders of the sex (X and Y) chromosomes present with fewer physical stigmata than other genetic disorders. As a result, they are often undetected during infancy and may only be diagnosed later, when the child starts to exhibit delays. Sex chromosome disorders include Klinefelter's syndrome (usually an XXY chromosome complement in males, instead of the usual XY), Turner's syndrome (X0 in females, instead of the usual XX), and fragile X syndrome. Batshaw et al. (2007) provide a detailed discussion of chromosomes and hereditary disorders.

Other Risks Identified after the Newborn Period

Not all children with special needs are identified at birth. As discussed earlier, others will be identified through parent or physician referral or through Child Find efforts later in infancy. Hearing impairment is one condition that may not be identified at birth. Many, but not all, states provide newborn hearing screening. In states where screening is not available, children with hearing impairments are not identified until sometime after the newborn period. Disorders without physical stigmata, such as autism, nonspecific intellectual disability, and specific language disorders, also are identified later in the prelinguistic or emerging language period. Children who experience abuse or neglect, too, are identified only after the newborn period has passed. All these children, though, have clear risks for communication development.

Any infant known or suspected to be subject to these conditions, then, would be considered at risk for communication disorders. Now that we know something about what these risk factors are, let's see what we as speech-language pathologists can do about them.

ASSESSMENT AND INTERVENTION FOR HIGH-RISK INFANTS AND THEIR FAMILIES IN THE NEWBORN INTENSIVE CARE NURSERY

Each year approximately 12% of infants begin life in the neonatal intensive care unit (NICU) (ASHA, 2004a; Bruns & Steeples, 2001). ASHA has recently outlined the roles that SLPs can play in the NICU (ASHA, 2004a). Some SLPs spend most of their workday assisting families in the NICU; other hospital-based SLPs may be called in to consult on the management plan of an infant being cared for in the NICU in order to provide assessment and intervention in several areas. We'll take a brief look at the basic areas to consider for prelinguistic infants: feeding and oral motor development, hearing conservation and aural habilitation, infant behavior and development, and parent-child communication, with reference to NICU infants in the next few sections. It is important to know, though, that practice in the NICU is a highly specialized area and most hospitals require extensive training or demonstration of specific competencies of SLPs who work in this setting. Infants in the NICU frequently have complex medication issues and very often therapy goals are secondary to keeping the infant physiologically stable. The following sections will serve only as an introduction to this broad topic. Gardner et al. (2010) provide a more in-depth discussion.

Feeding and Oral Motor Development

Assessment

The ability to take nutrition orally is one of the criteria for discharging infants from the NICU (McGrath & Braescu, 2004). As such, promoting oral feeding is an important aspect of helping prepare the child and family for life at home. Evaluating feeding and oral motor development in the high-risk newborn involves two components: chart review and bedside feeding evaluation. Alper and Manno (1996) suggest that chart review should yield information on adjusted gestational age, excess amniotic fluid at delivery that could signal a lack of intrauterine sucking and swallowing,

type and duration of intubation, respiratory disorders, and degree of family involvement.

Bedside feeding evaluation can be used to observe the infant's behavior and state during feeding, the effects of environmental stimuli on the infant's feeding behavior, vocalizations and airway noises during feeding, and reflex patterns. According to Jaffe (1989), reflexes that should be observed in the infant during feeding include the following:

1. **Suckling:** a primitive form of sucking that includes extension and retraction of the tongue as well as up-and-down jaw movements and loose closure of the lips.
2. **Sucking:** a more mature pattern, which differs from suckling in that more intraoral negative pressure is generated, the tongue tip is elevated rather than extended and retracted, lip approximation is firmer, and jaw movement is more rhythmic.
3. **Rooting:** causes the infant to turn the head toward the source of tactile stimulation (gentle rubbing) of the lips or lower cheek.
4. **Phasic bite reflex:** When teeth or gums are stimulated, usually by placement of the bottle or nipple in the mouth, the baby exhibits a rhythmic bite-and-release pattern that can be observed as a series of small jaw openings and closings.

When looking for these reflexes in the high-risk newborn, it is important to remember that they are typically seen in full-term babies. If a seriously premature infant does not exhibit them, we should not be too surprised. The presence or absence of these reflexes, though, will both determine the need for further assessment and contribute to the development of the feeding plan for the infant.

McGrath and Braescu (2004) and Ziev (1999) provide guidelines for determining whether a baby is developmentally ready to begin nipple feeding. Using a developmental evaluation, such as Brazelton and Nugent's (1995) *Neonatal Behavioral Assessment Scale* or Lester and Tronick's (2004) *NICU Network Neurobehavioral Scale*, we can estimate developmental level and determine whether the premature infant has developed sufficiently to engage in some form of nipple feeding. Additional considerations for beginning oral feeding are presented in Box 6-1.

BOX 6-1 Considerations for Readiness for Oral Feeding

Gestational age: Generally at least 35-37 weeks.
Severity of medical condition: Respiratory disorders contribute to delays in readiness for oral feeding.
Respiratory/cardiovascular stability: Infants needing oxygen support, with apnea, or periodic breathing are more delayed in readiness for oral feeding.
Motoric stability: Oral tone, posture, and quality of oral movements should be evaluated.
Coordination of sucking, swallowing, and breathing: Mature suck consists of ten or more sucking bursts with breathing interspersed with suck/swallow; consider evaluating in non-nutritive sucking.
Behavioral state organization: Infant must be able to maintain an alert state long enough to complete feeding.
Demonstration of hunger: Exhibits rooting, may exhibit non-nutritive sucking, crying may be weak.

Adapted from McGrath, J., and Braescu, A. (2004). State of the science. *Journal of Perinatal and Neonatal Nursing*, 18, 353-368.

In addition to observational assessment, several formal procedures are available for collecting information on feeding and oral skills. These are outlined in Appendix 6-4. Howe et al. (2008) reviewed seven feeding assessments and found limitations in the representativeness of their samples, which, in turn, limit the soundness of their psychometric properties. They reported that Neonatal Oral-Motor Assessment Scale (Braun & Palmer, 1986) showed more consistent psychometric properties than the others, although, it, too, had limitations. They cautioned that results of any neonatal feeding assessment tool needs to be interpreted with caution, because of these limitations.

Barlow et al. (2010); Jelm (1990); Kedesdy and Budd (1998); Lowman, Murphy, and Snell (1999); Morris and Klein (2000); VanDahm (2010); and Wolf and Glass (1992a) provide additional information on infant and childhood feeding disorders. If formal assessment procedures are unavailable, informal interviews also can be used to gather data about the infant's feeding and oral skills. Box 6-2 provides some of the questions that could be asked in an informal interview.

Children with disabilities or those with tracheostomies often experience *gastroesophageal reflux*, or the backward flow of contents of the stomach up into the esophagus. This condition can seriously interfere with nutritional intake and desire to eat by mouth (Eicher, 2002). Special diagnostic procedures, which will be described a bit later, are often undertaken by the physician when this condition is suspected.

Management

The results of the feeding and oral assessment provide the clinician with information necessary to make decisions about whether feeding therapy is needed and what aspects of the feeding and oral behavior ought to be addressed. Very often, though, because of the neurological immaturity of the infant in the NICU or because of other medical conditions contributing to intolerance of enteral feeding (by way of the intestines), which can result in excessive vomiting and lead to esophagitis and oral defensiveness, oral feeding may not be an option. In these cases, tube feeding may be initiated. The decision to tube feed is usually made by the physician,

BOX 6-2 Questions for Informal Assessment of Feeding and Oral Skills

Who is the baby's primary feeder?
 What positions have you tried for feeding?
 Does one type of nipple seem to work better than another?
 Can the baby suck vigorously?
 How much milk can the baby take in one feeding?
 How long does the feeding take?
 How long does the baby go between feedings?
 How many feedings a day is the baby getting?
 Does the baby seem to be alert during feedings? Does he or she look at the feeder?
 How well does the baby control the jaw, head, and trunk during feeding?
 Does the baby gag, choke, cough, or bite during feeding?
 Does the baby have trouble or seem to delay swallowing?
 Can the baby coordinate sucking, swallowing, and breathing?
 Does drooling interfere with feeding?

and the SLP may not be consulted. But, as Imhoff and Wigginton (1991) pointed out, the SLP can be an important advocate for the parents in understanding the tube feeding decision and its consequences, in helping them to ask appropriate questions of the medical staff, and in making the eventual transition from tube to oral feeding. To serve in this advocate role, the SLP should be familiar with the various forms of tube feeding.

Three options currently are in use for nonoral feeding, and each has certain advantages and disadvantages for the baby and the family. The *nasogastric*, or *N-G*, tube is inserted through the nose and descends down the pharynx and into the stomach, whereas the *orogastric*, or *gavage*, tube is inserted through the mouth; a *nasojejunal* tube might also be used; this is inserted into the second part of the intestine. These methods preclude oral feeding while they are in place and can lead to hypersensitivity of the oral cavity. Both also are visible and remind the parents every time they see the child about how sick the baby is. Physicians generally prefer these methods because they do not involve the surgical risk of the third option, the *gastronomy*, or *G-tube*. The G-tube brings food directly into the stomach and frees the oral cavity for exploration as well as for supplementary oral feeding and is typically used when nonoral feeding will be needed for an extended period of time.

Infants who need nonoral feeding for extended periods, particularly if they need endotracheal tubes to help them breathe as well, may show decreased sucking and oral motor development (Barlow et al., 2010; Comrie & Helm, 1997). An important contribution that the SLP can make to this situation is to encourage parents and medical personnel to offer the baby opportunities for non-nutritive sucking (e.g., pacifier) during the tube feeding. This will help strengthen the sucking reflex and also help the baby learn to associate sucking with feeling contented from feeding. Other oral stimulation, such as stroking the cheek, lips, and gums, may also help make the child ready for oral feeding (Fucile, Gisel, & Lau, 2005). Arvedson et al. (2010) showed that non-nutritive sucking alone and combined with oral stimulation showed strong positive results for reducing transition time to oral feeding. The SLP also can take the time, which medical personnel will not always be able to do, to explain why the feeding tube is needed and to reassure the family that normal feeding will eventually be achieved. Furthermore, the SLP can encourage the family to ask about supplementary oral feedings and may encourage the parents to ask the physician about using a G-tube to minimize effects on oral development if prolonged nonoral feeding (more than 1 month) is necessary.

If our assessment suggests that the baby is ready to graduate from nonoral to oral feeding, or is able to feed orally from the first, the SLP can use several techniques to help the infant succeed. Spatz (2004) discussed ways to promote breastfeeding for premature infants. These include working with nurses to help mothers maintain their milk supply by pumping and to safely store and track each mother's milk, encouraging the mother to hold the baby skin-to-skin during nonoral feeding and to provide non-nutritive sucking experiences while holding the baby at the breast. When making the transition to breastfeeding, the SLP can help with positioning the infant, using a "football" hold to support the head and neck. Although hospitals are more likely to encourage breastfeeding for premature infants than they were only a few years ago, since breast milk contains many nutrients and antibodies that are beneficial to the baby's health, some premature or high-risk infants may be unable to nurse, and their feeding times will be long and closely spaced, making nursing very difficult for the mother. Some mothers may still want to pump breast milk for the baby to drink

from a bottle, and many NICUs provide breast pumps for this purpose. When the mother feels she wants to contribute to her infant's well-being in this way, she should certainly be encouraged to do so. Fletcher and Ash (2005) discuss the importance of working with other professionals to support mothers who wish to breastfeed babies in the NICU. However, mothers should also be guided to understand that the infant can thrive on formula as well. Interaction is just as important, and perhaps more important to the babies' development, than the milk they drink. In counseling the mother of a baby in NICU, the SLP will want to help her do for the baby what she can do best and to feel that she is making a contribution to the baby's overcoming a difficult start. If the mother can nurse or express milk, fine. If a particular mother cannot or feels uncomfortable with these options, she can help her baby in many other ways. The SLP can play a crucial role in helping the mother to understand the importance of interaction and communication in the baby's development and in making her see that these are her most crucial contributions to her child's well-being. It is especially important to stress to these mothers that feeding time must be communicative as well as nutritional and to encourage mothers to develop interaction and communication early in the feeding process.

Feeding is almost as important to the mother's development as it is to the infant's. If a mother cannot feed her baby, her sense of herself as the primary source of nurture in the baby's life is seriously threatened. The SLP developing a feeding plan for a baby in the NICU can help the mother to feel her way toward this nurturing role. Specific techniques and instruction for facilitating feeding by either breast or bottle can be provided, such as the following:

1. *Positioning.* Jaffe (1989) suggested that the premature baby be placed in a flexed position, with the chin tucked into the neck and the shoulders and arms pressed forward. This is an ideal "cuddling" position and can aid in bonding as well as feeding. Ideal positioning also can be achieved by placing the baby in a positioning device such as "Boppy" pillow, infant seat, or tumbleform seating. Hall, Circello, Reed, and Hylton (1987) advocated keeping the child's face near the feeder's to encourage eye contact and social interaction. Comrie and Helm (1997) provide additional detailed positioning alternatives. The mother's comfort and the baby's success are most important in deciding on a position for feeding. Trial and error may be necessary to find the best position.
2. *Jaw stabilization.* The mother can place her thumb or finger on the baby's chin, just below the lower lip, another finger on the temporomandibular joint, and a third finger under the chin. This support allows her to stabilize the head and jaw and to provide more control as the infant sucks. This control on the mother's part should be gradually faded as the infant's feeding skills develop.
3. *Negative resistance.* Comrie and Helm (1997) suggest using negative resistance to help infants who bite rather than suck or have an inefficient sucking pattern. As the infant pulls on the nipple during sucking, the feeder tugs gently back. This often stimulates a longer and stronger suck.
4. *Using specialized feeding equipment.* Comrie and Helm also suggest that nipple characteristics can influence sucking patterns, and suggest that if breastfeeding is not possible, nipples with various characteristics of flow rate, suction, and compression should be tried, as well as angled bottles. Spatz (2004) advocates using a nipple shield for breastfeeding mothers, to increase baby's milk intake.

5. *Modifying temperature and consistency.* Alper and Manno (1996) point out that chilling liquids has been tried to increase swallowing rate and decrease pooling of liquid in the pharynx. However, the main effect of this change may be to thicken the liquid, which may make it easier to swallow. Formulas also can be thickened by adding rice cereal.
6. *Oral stimulation in feeding.* McGowan and Kerwin (1993) suggested providing oral stimulation during feeding. They advised having parents use the following sequence to introduce bottle feeding:
 - a. Stroking the nipple on the side of the baby's cheek to elicit a rooting reflex.
 - b. Touching the nipple to the center of the lips and gum surface to produce mouth opening.
 - c. Allowing the baby to close on the nipple and start sucking, then stroking upward on the palate in a rhythmic motion with the nipple to encourage continued sucking.
7. *Nonfeeding oral stimulation.* In addition to being encouraged to touch and stroke their babies' bodies in the NICU, mothers also should be encouraged to provide gentle stimulation to the baby's face, rubbing it gently with fingers or soft toys and providing non-nutritive sucking of a pacifier or finger whenever possible (Fucile, Gisell, & Lau, 2005). McGowan and Kerwin (1993) gave some specific suggestions for oral stimulation activities, including the following:
 - a. Putting a finger (nail down) in the baby's mouth and rubbing the palate with an upward motion (midsection to front) to stimulate non-nutritive sucking.
 - b. Rhythmically stroking the midsection of the tongue, front to back.
 - c. Rubbing the infant's cheeks, one at a time, with a circular motion.
 - d. Tapping around the baby's lips in a complete circle.
 - e. Placing a finger or toothbrush in the mouth and massaging the upper and lower gums.

Additional resources for assessing and managing infant feeding problems include Alper and Manno (1996); Arvedson and Brodsky (1993); Eicher (2002); Johnson-Martin, Hacker, and Attermeier (2004); Kedesdy and Budd (1998); Lowman, Murphy, and Snell (1999); McGrath and Braescu (2004); Morris and Klein (2000); Spatz (2004); Tuchman and Walter (1993); van Dahm (2010); and Wolf and Glass (1992a).

Hearing Conservation and Aural Habilitation

Forty-four states mandate hearing screening for all newborns in the NICU. But, as we discussed earlier, the NICU itself may be hazardous to the baby's health. Clark (1989) reported that the incubators, cardiorespiratory monitors, and ventilators present in the NICU can generate noise levels of more than 85 dB, which not only interferes with sleep but may result in hearing loss by means of cochlear damage. This risk to hearing is in addition to the high incidence of hearing loss associated with many of the syndromes and conditions that resulted in the child being placed in the NICU in the first place. As we saw earlier, many congenital and genetic syndromes affect the development of the auditory structures, and hearing loss is one of the most important causes of the language disorders we see in such children. The SLP can play a crucial role in conserving the hearing of the high-risk newborn by making sure

that aural habilitation is part of the management plan if screening indicates hearing loss. Further, the SLP should encourage the parents to have the infant's hearing tested by an audiologist periodically throughout the child's early years, even if losses are not identified during the newborn period. In this way any loss that occurs can be treated at the earliest possible time.

Child Behavior and Development

Assessment

Sparks (1989) emphasized that the purpose of assessment for infants should *not* be to predict future behavior, but to determine the infant's *current* strengths and needs. First, it is important to know as much as we can about what risks the infant faces. This knowledge can help us decide how much and what kind of intervention to propose. If the child has DS, for example, we know that the risk for future speech and language delays, as well as for middle-ear dysfunction, is high. This knowledge may lead us to argue more strongly for early communication intervention than we might in the case of a child with prematurity alone. Careful interviewing of family and medical staff, as well as medical chart review, can provide this information.

Second, we need to evaluate the infant's level of physiological organization. The premature infant's functioning is immature in every way. Even the simplest ability to maintain physiological stability is affected. Premature infants experience irregular respiration; color changes; bodily instability, including jitteriness and flaccidity; and disorganized patterns of alertness. The infant's level of behavioral organization and homeostasis will, in large measure, determine the ability to participate in interactions. So an important part of the assessment of the at-risk newborn involves evaluating the extent to which the baby can maintain physiological and attentional states.

The *Neonatal Behavioral Assessment Scale* (Brazelton & Nugent, 1995), *The Neurological Assessment of the Preterm and Full-term Newborn Infant* (Dubowitz, Dubowitz, & Mercuri, 1999), the *Naturalistic Observations of the Newborn, Assessment of Preterm Infant Behavior* (Als, 1985), the *Assessment of Preterm Infant Behavior (APIB)* (Als, Lester, Tronick, & Brazelton, 1982), *Developmental and Therapeutic Interventions in the NICU* (Vergara & Bigsby, 2004), and the *NICU Network Neurobehavioral Scale* (Lester & Tronick, 2005) are instruments designed to look at a range of abilities for infants 28 to 40 weeks of gestational age. They help the clinician to identify the conditions under which the baby functions best, what places stress on the baby, how much handling and stimulation the baby can tolerate, how easily the baby's homeostasis is disrupted, what supports are useful to the baby in maintaining self-control, and how much endurance the baby has for interactive functioning. Many NICUs use these instruments routinely to evaluate patients. When this evaluation has been done by medical staff, the SLP should carefully review the results for information that will help in the planning of a communicative intervention program. If no formal instrument is routinely used, the SLP should consider administering a developmental assessment.

Management

According to Gorski (1983), the goal of intervention for the baby in the NICU is to achieve stabilization and homeostasis of physiological and behavioral states and to prevent or minimize any secondary disorders that might be associated with the child's condition, rather than to attain milestones appropriate for full-term

babies. The best way for us to achieve these goals is to become a member of the NICU team and to earn the respect of the medical staff for our in-depth knowledge of early communicative and oral-motor development. When this has been achieved, the SLP can offer suggestions that will benefit communicative development. Gorski (1983), Griffer (2000), Nugent et al. (2007), and VandenBerg (1997) advocated developmentally supportive care that uses strategies like the following:

1. Encourage careful monitoring both of noise levels and infant hearing within the NICU.
2. Develop staff awareness of the dangers of ototoxic effects of medications.
3. Foster sensitivity to laryngeal damage from endotracheal tubes (Sparks, 1984).
4. Work to alleviate sensory overstimulation because of constant bright light.
5. Suggest ways to counteract the dangers of low language and interactive stimulation that can result from infrequent handling in the NICU.
6. Encourage consideration of the oral-motor consequences of continued use of N-G and gavage tube feeding, bearing in mind the surgical risks that G-tube feeding entails. The SLP can help families and medical staff to work together to consider how these risks can be balanced.
7. Advocate for the importance of non-nutritive sucking and oral stimulation to aid in the baby's oral-motor development.
8. Educate staff about the efficacy of early intervention (Rossetti, 2001).
9. Provide information about services offered by other disciplines (e.g., SLP, occupational therapy, physical therapy, counseling) that may be of help to families of babies in the NICU.
10. Support parents in achieving their goals for the child during the NICU stay.
11. Encourage parents to talk to, touch, and hold the baby; help with positioning.
12. Help parents recognize, understand, and interpret the infants' signals; help time caregiving and interaction to promote the infants state regulation and allow for natural sleep-wake cycles.

Parent-Child Communication

As we've seen, the newborn in the NICU is at risk for an inadequate interactive experience because medical needs and the appearance of frailty make it difficult for parents to respond to the baby in the usual way. Furthermore, the infant's neurological immaturity may render the baby less able to take advantage of the interactions that the parent offers. Let's see how the SLP can facilitate the parent-infant interaction in the NICU.

Assessment

Assessing Infant Readiness for Communication

Information gathered from an instrument, such as the *APIB*, will help identify the level of interactive, motor, and organizational development that the infant in the NICU is showing. This information is crucial for deciding whether the infant is ready to take advantage of communicative interaction. Gorski, Davison, and Brazelton (1979) defined three stages of behavioral organization in high-risk newborns. The child's state of organization determines

Communication intervention for at-risk infants can begin in the newborn intensive care unit.

when he or she is ready to participate in interactions. These states include the following:

1. *Turning In* (or physiological state). During this stage the baby is very sick and cannot really participate in reciprocal interactions. All the infant's energies are devoted to maintaining biological stability.
2. *Coming Out*. The baby first becomes responsive to the environment when he or she is no longer acutely ill, can breathe adequately, and begins to gain weight. This stage usually occurs while the baby is still in the NICU, and this is the time when he or she can begin to benefit from interactions with parents. It is essential that the SLP be aware when this stage is reached so that interactions can be encouraged.
3. *Reciprocity*. This final stage in the progression usually occurs at some point before the baby is released from the hospital. Now the infant can respond to parental interaction in predictable ways. Failure to achieve this stage, once physiological stability has been achieved, is a signal that developmental deficits may persist.

An important function that the SLP can serve in fostering communicative development in an infant in the NICU is to acquaint the parents with this progression and help them to learn from the medical staff when the child turns the corner from the first to the second stage. At this time, more active parental involvement with the infant should be encouraged by the SLP.

Assessing Parent Communication and Family Functioning

Several instruments are available to assess parent-child communication. These may be used once the baby is ready to participate in communicative interactions. The *Parent Behavior Progression* (Bromwich et al., 1981) is an instrument that provides a clinician with guidelines for observing a parent's behavior with the infant to assess what the parent needs in order to improve or maximize the value of the interactions. This instrument rates the parent's

apparent pleasure in the interaction; the sensitivity of the parent to the child's behavioral cues; the stability and mutuality of the interactions; and the developmental appropriateness of the parent's choice of actions, objects, and activities. The *Observation of Communicative Interaction* (Klein & Briggs, 1987), *Newborn Behavioral Observations System* (Nugent et al., 2007), and *Parent-Infant Relationships Global Assessment Scale* (Aoki, Iseharashi, Heller, & Bakshi, 2002) are similar instruments.

Some danger exists, though, in using formal procedures to assess parent-child communication and family functioning. Although communication is, of course, a two-way street, we do not want to convey to the family in any way that we think they are the problem. As Slentz and Bricker (1992) pointed out, when parent-child interactions or family function are assessed, the implication to family members is often that they have a problem that needs assessment or that their child has a problem because they have a problem. Slentz, Walker, and Bricker (1989) found that the most threatening aspect of early intervention for parents of handicapped children is the assessment of the family. Mahoney and Spiker (1996) discuss similar concerns. The intent of IDEA, through the IFSP, is to provide support to the family in promoting the infant's development. Although the IFSP mandates participation of the family and identification of *their* "priorities and concerns," it does not specifically mandate formal assessments.

A simple and effective way to find out about family priorities and concerns is to ask. Slentz and Bricker (1992) suggested that the time it would take to do extensive formal assessment of family functioning is better spent developing a relationship with the family and giving them the opportunity to talk at length with the clinician about the frustrations and joys of raising their baby. This formation of an alliance with the family is more likely to lead to valid insights into their strengths and needs than will misguided attempts at pseudoscientific assessment. Cripe and Bricker (1993) have developed the *Family Interest Survey*, not to evaluate the family, but to simply find out what they think about their child's needs. It is intended to be a nonjudgmental means of identifying areas of the family's interest in both intervention goals and social services and can help the SLP see the family's perspective on the child's needs and the services required to provide for them. The *How Can We Help* survey (Child Development Resources, 1989) is a similar instrument. This survey appears in [Appendix 6-5](#).

What about the truly dysfunctional family? The one that presents a danger to the infant or appears unable to meet the baby's needs in an even minimally adequate way? Here the SLP's responsibility is referral to appropriate social services and advocacy for the services the family needs to provide for the baby. Even if formal assessment were needed to identify such a family, the SLP would not be able to provide the financial assistance, drug and alcohol counseling, and other services that would be required to set this family on the right track. A straightforward statement of the SLP's concerns about the family to the appropriate agency is enough to alert social service personnel to the family's situation. In truth, we should be aware that the family's needs will not always be adequately addressed. Since this is the case, the justification for intrusive and threatening probes into the family's psyche seems even less compelling. Again, the role of the SLP as advocate and ally is most important to preserve, to get the parents to cooperate to any extent they can in enhancing the baby's learning environment.

As we've discussed, one of the best ways to find out about family members' priorities and concerns is to talk with them. In

discussing how a family can best cope with a handicapped or at-risk child, it is a good idea to remember that the family is probably experiencing a good deal of shock, grief, guilt, confusion, fear, and a feeling of loss of the perfect baby they dreamed of having. They also may be experiencing information overload as a result of the well-meaning efforts of the hospital staff to keep them up-to-date on their baby's condition and prospects. The SLP is uniquely suited to give the family the opportunity to express these conflicting feelings and to be a model for the family in listening to and responding to their needs, as we hope the family will do for the infant.

The feelings the family is expressing may not be pretty. They may be angry at the medical staff or at no one in particular at the blow they have been dealt and the burden they will have to carry, perhaps for the rest of their lives. Who wouldn't be angry and frightened? The notion of family-centered intervention dictates that we acknowledge and respect both the unrelenting difficulties parents of babies in the NICU are experiencing and the ways in which they are able to cope. Our goal is to support the family, not to engineer them; to give them the information they need at the present time and to be ready to provide more information when it is wanted; and to respond to the family's needs and desires rather than to dictate what they should do. Thus a family-centered approach involves not a complicated psychology, but rather a simple, human attempt to treat others as we would wish to be treated if we were experiencing the difficult transition that the NICU infant's family must face.

Management

A recent innovation in the care of the medically stable infant in the NICU is "kangaroo care" (Rossetti, 2001; Ruiz-Palaez, Charkap, & Cuervo, 2004). This technique involves skin-to-skin contact between parent and child during the NICU stay. Parents are encouraged to swaddle the infant to their unclothed chest for about 30 minutes each day. The method has been shown to be associated with decreased length of hospital stay; shorter periods of assisted ventilation; increased periods of alertness; and, perhaps as importantly, with an enhanced sense of nurturance of the child on the parent's part (Dodd, 2005; Ruiz-Palaez, Charkap, & Cuervo, 2004). This technique seems to have great potential for improving parent-child interactions during the infant's first days, and can be used as part of the preparation for oral feeding, as we discussed earlier.

Still, the very sick neonate may not be ready to take advantage of interactions with parents during the period of acute illness for some time after birth. When this is the case, SLPs can still encourage one important activity in parents: we can help parents to learn to observe their babies and, specifically, to identify states the baby is exhibiting. Learning to identify the baby's state will be very useful for parents when the time arrives to begin communicative interactions with the baby. Babies are only receptive to interactions in certain states. A parent who can recognize these states and use them as interactive opportunities will have a better chance to engage the baby's attention and elicit reciprocity. Brazelton (1973) gave a description of the various states seen in the healthy newborn. Each state carries implications for the kinds of caregiving activities that can go on when the infant is in that state (Blackburn, 1978). These states and their implications are summarized in [Table 6-1](#).

We can facilitate parents' identification of the infant's state by encouraging them to observe their babies and by talking with them about what they see. We can use the behaviors listed in [Table 6-1](#)

TABLE 6-1 Infant States*

State	Behaviors	Implications for Interaction
Deep sleep	1. Body still, except for occasional twitch 2. Eyes closed 3. Still face 4. Breathing smooth 5. Threshold to stimuli high—only very intense stimuli will cause arousal.	Little possible, adults will do better to wait to feed or interact until child arouses naturally
Light sleep	1. Some body movement 2. Eyes flutter beneath closed lids 3. May smile or cry briefly 4. Breathing irregular 5. More responsive to stimuli; may arouse to drowsy state if stimulus occurs	Makes up largest part of newborn sleep pattern; brief fuss sounds may cause adults to try to feed, rouse, or interact with babies before they are ready.
Drowsy	1. Variable activity, usually smooth 2. Eyes open and close, appear dull 3. Face often appears still 4. Breathing irregular 5. Reacts to stimuli, but reactions are delayed; this state often changes after reaction	Infants left alone in this state may return to sleep, but if parents provide something for the baby to look at, listen to, or suck on, baby may be aroused to a more responsive state.
Quiet alert	1. Little bodily movement 2. Eyes brighten and widen 3. Face appears bright 4. Breathing regular 5. Attends to environment stimuli	Providing something for baby to look at, listen to, or suck may maintain this state, which is ideal for interaction.
Active alert	1. Much bodily movement 2. Eyes are open and bright 3. Much facial movement 4. Breathing irregular 5. increasingly sensitive to disturbing stimuli (e.g., hunger, noise)	Parents can cuddle and console to bring baby to a less aroused state.
Crying	1. Increased motor activity, color changes 2. Eyes may be tightly closed or open 3. Facial grimaces 4. Breathing irregular 5. Highly responsive to unpleasant stimuli	Tells parents the child has reached his or her limits; needs to be fed or consoled.

Adapted from Blackburn, S. (1978). State organizations in the newborn: Implications for caregiving. In K.E. Barend, S. Blackburn, R. Kang & A.L. Saetz (Eds.), *Early parent-infant relationships. Series 1: The first six hours of life, module 3*. White Plains, NY: The National Foundation/March of Dimes.

*"State" is a group of behaviors that regularly occur together, including (1) bodily activity, (2) eye movement, (3) facial movement, (4) breathing pattern, and (5) responses to stimuli.

to distinguish deep sleep from light sleep, for example, and discuss what the parent would do differently, depending on which type of sleep was observed. We also can encourage parents to learn to distinguish among the various waking states and ask similar questions about these. Although the very sick neonate may exhibit few states of alertness, the parent can be encouraged to observe alertness in other babies in the NICU and to identify the fleeting alert states that do occur in the baby who is still in the Turning In stage. When more frequent alert states do emerge, the parents will be ready to recognize and take advantage of them. Hussey-Gardner's *Understanding My Signals* (1999) is also helpful for this purpose.

Once the infant has progressed to the Coming Out stage and can take advantage of parental communication, our most important job is to get parents to start communicating with their babies. By keeping in close touch with medical staff, we can be sure that parents are alerted to their baby's transition to this stage. Once it occurs, we will be in a position to encourage the parents to use their knowledge of the baby's states to tune in on when the baby is alert and able to interact. We can encourage the parents to look at, handle, talk to, sing, and show things to the baby during this state. A second

important aspect of these interactions is to help the parent identify when the infant can no longer interact and allow the baby to recoup his or her resources so that further interaction will be possible later.

Parents can be helped to identify the infant's signs of stress, such as averting the gaze, turning the head away, spreading the fingers, arching the back, and grunting. Parents can be encouraged to see these signs of stress as a natural part of the baby's transition from one state to another, rather than as a rejection of their efforts to interact. We can teach parents to give the baby "time out" to reorganize. They can be asked not to try to re-establish mutual gaze if the baby has broken it. Instead, they should be counseled to wait for signals, such as bodily quieting and a reinitiation of mutual gaze by the baby, that he or she is ready for more interaction. These same skills can be fostered during feedings, helping the parent to become aware of the baby's readiness both to feed and to interact in this very important communicative context.

Rossetti (2001) suggests that another way to increase the parents' role with the newborn in the NICU is to encourage the parent to participate in charting the child's behavior. The SLP can discuss this option with other staff and try to make them understand the

advantages of enlisting the parents' help in the big job of keeping the copious records required in the hospital. Not only will the parents feel more a part of the baby's care team, but charting can help them learn to be better observers of the child's behavior, a skill that will serve them well throughout the child's development.

ASSESSMENT AND INTERVENTION FOR PREINTENTIONAL INFANTS AND THEIR FAMILIES: 1 TO 8 MONTHS

Although life with a baby in the NICU is difficult, taking that baby home for the first time can be just as daunting. In the hospital the parents may have felt isolated and shut out of the baby's care; at home the same parents may feel overwhelmed by the responsibility that they must now face alone. If the IFSP includes follow-up by the SLP during this difficult period, there are many ways in which we can support the family in its new capacity.

Before learning what they are, though, let's make sure we understand the terminology used to describe this period of development. Infants in this phase are referred to as *preintentional* because they have not yet developed the cognitive skills to represent ideas in their minds and to pursue goals through planned actions. Bates (1976) referred to this stage of development as "perlocutionary." This term implies two important things: first, infants do not intend any particular outcome by their behavior, and secondly, that adults act as if they do. Adults' willingness to attribute intentionality to the young infant's behavior is one way babies are "taught" how to have these intentions, which will eventually lay the basis for communication later in the first year of life. Let's examine the same four areas that we looked at for the newborn to see how the SLP can provide effective services to preintentional infants and their families.

Feeding and Oral-Motor Development

Feeding Assessment

Many infants who leave the NICU continue to show feeding problems at home throughout the first year of life (Swift & Scholten, 2010). The same instruments that we discussed using to assess

feeding and oral-motor development in the newborn are relevant for assessing these older infants. Similarly, informal interviews that include questions such as those given in [Box 6-2](#) also can be used to gather information about the child's feeding ability. Toward the middle of the first year of life, though, the normally developing infant begins to acquire new feeding patterns that facilitate the introduction of solid foods into the diet. These patterns include integrating the front-to-back movement of the tongue used in sucking with rhythmic up-and-down jaw movements to produce the "munching pattern" that enables the child to eat solids (Eicher, 2007). During the next year or so, additional patterns develop. These are summarized in [Table 6-2](#). Informal oral-motor assessment of the preintentional infant can include attempts to observe these patterns during feeding at the appropriate developmental level.

For infants with tracheostomies or neurological involvement, some specialized assessments may be necessary to evaluate the safety of oral feeding, particularly for solid foods. ASHA (2004a) holds that some of these studies can be carried out by SLPs, such as the following:

Cervical auscultation detects changes in upper aerodigestive tract sounds and is the most noninvasive of these measures.

Videofluoroscopic swallowing function studies, similar to those used with adults who have acquired dysphagia, can also be used to examine oral and pharyngeal movement during feeding and to assess risk for aspiration in children with neurological involvement.

Ultrasound studies allow for the visualization of relations between movement patterns and oral/pharyngeal structures.

Endoscopy involves passing a fiberoptic tube through the mouth down the esophagus and into the stomach while the child is sedated.

Other procedures are completed by medical personnel. Eicher (2007) and Lefton-Greif and Loughlin (1996) described additional tests that may be used to assess danger of aspiration or gastroesophageal reflux (GER):

The *upper gastrointestinal study (upper GI)* involves the child's ingesting a liquid containing barium that is visible on x-ray.

This allows a radiologist to observe structural abnormalities or reflux into the esophagus.

TABLE 6-2 Development of Feeding and Oral-Motor Skills

Age (Mo)	Food Type	Oral-Motor Skill	Development Skill
0-4	Liquid	Suckle on nipple	Head control acquired
4-6	Purees	Suckle off spoon Progress to sucking	Sitting, hands to midline
6-9	Soft chewables	Vertical munching "Sippy" cup drinking Limited lateral tongue movements	Hand-to-mouth reach, grasp Finger feeding; assist with spoon
9-12	Lumpy textures	Independent "sippy" cup drinking	Pincer grasp Grasps spoon
12-18	All textures	Lateral tongue action Straw drinking	Scoops food to mouth Increased independence in feeding
18-24	More chewable food	Rotary chewing	Independent walking Can obtain food/nonfood objects on own
24	Tougher solids	Mature chewing	Total self-feeding Use of fork, open cup

Adapted from Arvedson, J., & Lefton-Greif, M. (1996). Anatomy, physiology and development of feeding. *Seminars in Speech and Language* 17, 261-268; and Jaffe, M. (1989). Feeding at-risk infants and toddlers. *Topics in Language Disorders*, 10(1), 13-25.

The *milk scan* also uses a radioactively marked fluid. Here the radiologist sees where the marker fluid settles. If it is seen in the lungs, aspiration can be inferred.

Additional assessments that might be required include the following:

Radionuclide imaging studies (scintigraphy) help to quantify esophageal and gastric emptying and aspiration and provide multiple static images of concentrated regions of tracer residue over prolonged periods.

The *pH probe* measures acidity by placing a nasogastric-like tube at the junction of the stomach and esophagus. The probe at the end of the tube can detect acid that refluxes through an incompetent valve from the stomach. Results of this assessment can help to determine positioning needs during feeding to avoid reflux. The physician can then visualize the tissues and take small biopsy specimens to examine for inflammation.

Methylene blue screening is used to determine whether a child with a tracheostomy is aspirating food into the lungs, which can lead to recurrent pneumonia. In this procedure, food is dyed and evidence of emission of dye in the tracheal stoma, which would indicate aspiration, is monitored.

The pH probe and gastroesophageal endoscopy are considered the “gold standards” in the evaluation of feeding and swallowing (Eicher, 2007).

Vocal Assessment

In addition to concern about feeding, we also have concerns at this stage of development about the infant's vocal ability. Proctor (1989) has provided a detailed instrument for assessing the baby's vocal skills from birth to 12 months. Bleile and Miller (1993) and Mitchell (1997) also provided guidelines for this assessment. Figure 6-1 presents a worksheet for assessing early vocal development adapted from these sources. Mitchell (1997) suggests that the sample consist of what she calls “comfort state” vocalizations. These include sounds the child makes when in an alert and contented state and are typically heard during familiar caretaking routines, such as changing, feeding, bathing, or playing. Her findings indicate that 20 minutes is usually adequate to collect a sample of up to 70 vocalizations and that this constitutes a reasonably representative sample. If the infant becomes fussy, however, she suggests collecting the sample over several observations, until 50 to 70 comfort state vocalizations have been produced. Vocalizations included in the sample are those that contain a vowel-like and/or consonant-like element, are produced with an egressive air stream, and sound speech-like. Mitchell advocates practicing the analysis with a colleague until 80% to 90% agreement is reached on the classification of vocalizations.

To record the child's performance, the SLP begins by observing the child and parent and listening carefully to each vocalization produced by the child. Vocalizations are divided either by intonation contours, pauses, or an inhalation by the infant. If the child is vocalizing frequently, it may be necessary to audiorecord the session for later analysis. In many cases, though, it will be possible to do the assessment in real time, especially when the clinician is familiar with the assessment recording form. The clinician then codes each vocalization heard during the observation according to the criteria on the form and notes it with a checkmark in the corresponding box in the “observed directly” column. For vocal behaviors listed at the child's developmental level (in the first column of Figure 6-1) that are not observed directly, the clinician can demonstrate the behavior for the parent and ask whether the child ever

produces that behavior. If so, a checkmark can be recorded in the “parent report” column on the form. If the parent reports that the behavior does not occur at home and the clinician does not observe it, a (—) should be recorded for that vocal behavior. If most behaviors at the child's age level are observed, the clinician can ask the parent about behaviors at subsequent levels. If the direct observation indicates few behaviors at the child's developmental level, the clinician can ask parents about behaviors typical of earlier levels. The clinician also can indicate on the form the vowel-like or consonant-like productions heard, using phonetic transcription, in the “phonetics/comments” column. The number of vocalizations produced in the time frame of the observation also can be recorded there.

Although this is not a norm-referenced assessment, Figure 6-1 may be used to help determine whether vocal development appears to be progressing appropriately and whether intervention ought to include stimulation of vocalization. The number of checkmarks and (—)s on the form can be used to determine the general stage of vocal development. The stage at which at least one appropriate type of vocalization occurs can be seen as the stage of vocalization in which the child is emerging. If this stage corresponds to chronological age, then vocal development can be considered to be progressing adequately.

One particularly important benchmark to be aware of is the emergence of what Oller and colleagues call *canonical babbling*. Oller, Levine, Cobo-Lewis, Eilers, and Pearson (1998) define canonical babbling as the production of well-formed syllables that consist of at least one vowel-like element and one consonant-like element that are connected in quick transition and are recognized to contain sounds similar enough to speech to be transcribable. Examples include /baba/, /dIdI/, /iba/, and /ta/. Oller et al. have shown that the failure to produce these syllables by 10 months of age predicts delays in the acquisition of words and word combinations in the second year of life. These forms are, then, an important benchmark to monitor as the child reaches the last quarter of the first year. Oller, Eilers, and Basinger (2001) show that parents can reliably report whether or not these forms are present in children's speech, so that for children over 10 months of age, parents should be asked if they hear these forms if the infant does not produce them during the assessment.

Other important features to note in the child's babbling are the rate of vocalization, proportion of consonants, and multisyllabic babbling (Mitchell, 1997). Rate of babbling is computed by counting the number of vocalizations (not syllables) and dividing by the number of minutes the sample includes. Although there are no norms for rate in infants younger than 12 months, in general the rate should increase with age. If rate fails to advance for 6 months or so, some stimulation of vocal production should be considered as part of the management program, and hearing should be assessed. Ratio of consonants to vowels also should increase during the first year. By 16 months, the sample should include more consonants than vowels. Babbling that contains more than one syllable also should increase during the first year and a half, and vocalizations that include more than one type of consonant should begin to appear by the end of the first year (Mitchell, 1997). An additional milestone is the beginning of the imitation of the intonation contour of the ambient language (Rothganger, 2003). The babble of children toward the end of the first year should begin to mimic the melody, or prosodic contour, of sentences. These milestones, too, can help determine whether vocal development is proceeding typically. This assessment can be repeated periodically to ensure that

Child's name: _____ Birthdate: _____
 Address: _____ Phone: _____
 _____ Parents: _____

	Observed directly	Parent report	Phonetics/comments
Stage 1 (birth to 2 months)			
Vocalization Types			
Crying with sudden pitch shifts, extremely high pitch			
Fussing or discomfort			
Vegetative sounds (burps, sounds accompanying feeding)			
Neutral sounds (grunts, sighs)			
Vowel-like sounds: (i, I, e, ʌ, u, U, o, a]			
Stage 2 (2 to 4 months)			
Vocalization Types			
Vowel sounds predominate, but a few consonants emerge (primarily velars and glottals)			
Marked decrease in crying (after 12 weeks)			
Begins consonant plus vowel; mostly "coo" and "goo"			
Begins to produce pleasure sounds, such as "mmmmm"			
Stage 3 (4 to 6 months)			
Vocalization Types			
Consistent production of consonant-vowel (CV) (syllabic) combinations			
Imitation of sounds in back-and-forth babbling games with others			
More variations in vowel production			
Number of consonant segments increases to include front stops and nasals			
Laughter emerges (around 16 weeks)			
Front sounds begin to predominate, including blowing "raspberries," bilabial trills, lip smacks			
Begins variation of intonational (pitch) contours, often when playing alone with toys			
Extreme pitch glides, such as yells, squeals, and low-pitched growls			
Stage 4 (6 to 10 months)			
Vocalization Types			
Canonical, repetitive, or reduplicated babbling (CV or CVCV-like structure) begins to appear ([mama], [dada], and [nʌnʌ])			
Consistent variation of intonational contours			
Early nonreduplicated CV sequences appear			
Parent may report hearing first word around 10 months			
Utterances produced with full-stop consonant (p, b, t, d, are most common)			
Short exclamations such as "ooh!" begin to appear			
Stage 5 (10 to 12 months)			
Vocalization Types			
Variegated babbling (successive syllables not identical) appears			
Variety of CV and CVC combinations with sentence-like intonation			
Syllables other than CVs produced			
Use of jargon, protowords, or phonetically consistent forms emerges			
Increased development of prosodic contours to match intonation patterns of ambient language			
Approximations of meaningful single words; phonological processes may operate on word approximations			

FIGURE 6-1 Developmental vocal assessment form. (Adapted from Proctor, A. [1989]. States of normal noncry vocal development in infancy: A protocol for assessment. *Topics in Language Disorders*, 10[1], 26-42; used with permission of Aspen Publishers; Bleile, K., and Miller, S. [1993]. Infants and toddlers. In J. bernthal [Ed.], *Articulatory and phonological disorders in special populations*. New York: Thieme; McCune, L., & Vihman, M. [2001]. Early phonetic and lexical development: A productivity approach. *Journal of Speech, Language, and Hearing Research*, 44, 670-684.)

vocal development is continuing and to determine the efficacy of any intervention that is initiated.

For children with a history of prematurity, corrected gestational age (CGA) should be used as the standard for comparison during the first year of life (Rossetti, 2001). CGA is computed by subtracting the number of weeks of prematurity from the child's chronological age. If, for example, Janice were assessed at 3 months after birth, her 8 weeks of prematurity would be subtracted from her chronological age of 12 weeks. Her CGA, then, would be 4 weeks, and vocal behaviors typical of a 4-week-old would be considered appropriate for her developmental level.

Managing Feeding

For the nursing or bottle-feeding infant, the same strategies we discussed earlier can be used to improve sucking and feeding behavior. Oral stimulation, in the form of gentle touching; encouragement of non-nutritive sucking; and presentation of safe items for the baby to mouth, such as soft rubber toys, a toothbrush, or teething ring, also can be encouraged. Care should be taken to help parents become aware of what items should and should not be mouthed. Balloons, coins, and toys with small parts are particularly dangerous.

As the baby approaches the second half of the first year, feeding of solid foods may be introduced, if assessment indicates that this will be safe for the infant. Babies with orofacial anomalies or conditions involving depressed muscle tone, such as DS, may have difficulty making this transition. Jaffe (1989) offered a series of suggestions for improving feeding skills, summarized in [Box 6-3](#). In addition, many of the suggestions presented in [Appendix 6-6](#) for feeding older prelinguistic clients also can be adapted for feeding

at-risk preintentional infants. The resources we outlined earlier for assessing and managing feeding in the newborn also will be helpful for addressing feeding issues at the preintentional stage of development.

Managing Vocal Development

For infants whose vocal behavior appears to be less frequent or less mature than would be expected for their age (or age corrected for gestational age in the case of premature babies), hearing should always be assessed. In addition, encouraging vocalization should be part of the intervention plan. As with any intervention developed for the infant, the family must be involved and will probably be the ones to deliver the intervention. Encouraging vocalization in an infant is an activity in which all family members, even siblings, can engage. The family should be encouraged both to talk and to babble to the baby. The clinician can demonstrate the kinds of vocalizations that the infant is ready to learn to produce. These can be identified from the form in [Figure 6-1](#) by choosing vocal behaviors that are produced rarely or not at all but are at the stage into which the child is emerging. For a child emerging into stage 2, for example, who is currently producing only /a/ and /u/ vowels, the clinician can demonstrate the other vowels that are appropriate at this level, such as /I/ and /i/, and can encourage everyone in the family to babble and sing these vowels to the baby. If the baby is producing a very low frequency of comfort vocalization in general, the clinician can encourage everyone in the family to imitate any comfort vocalization the baby produces, anywhere, anytime. Goldstein & Schwade (2008), showed that when caregivers coordinated their behavior with their infants' babbling, infants increased their rate of vocalization and vocalized more advanced

BOX 6-3 Suggestions for Improving Feeding Skills

Sit below the baby's eye level to feed—This will help to control head flexion.

Start with single-consistency foods—Foods with more than one consistency, such as soups or packaged cereal with milk, may present problems resulting from lack of discrimination and coordination.

Vary texture gradually—Use applesauce, cereal, cracker crumbs, wheat germ, or yogurt to vary consistency until an optimal form is found. Avoid foods that are lumpy or extreme in temperature. Experiment until foods that child will accept are found.

Start with unheated food—gradually alternate temperatures, tastes, and textures when feeding.

Tap the lip or tongue to alert the child prior to presenting the bite.

Present small amounts of food on the spoon in early spoon feeding—Present the spoon from just below mouth level and withdraw it straight out to prevent hyperextension of the neck; press on the center in the front part of the tongue to inhibit bite reflex and encourage lip closure around the spoon.

Minimize spoon-to-teeth/jaw stimulation to decrease elicitation of bite reflex.

If the child bites the spoon, wait for the bite to be released. Don't pull against the spoon. Use coated or non-metal spoons.

Avoid constant face wiping. When wiping a child's face, tell him or her what you are going to do before you do it.

Identify preferred tastes—Finding foods that the baby likes may be more important than a balanced diet in the early stages.

Present a bite of a new or seldom-eaten food between bites of favorite foods.

Mix a small amount of a new food in with a favorite food to increase acceptance. Slowly decrease the amount of the favorite food in each subsequent bite.

Improve chewing—When child is ready, use crunchy foods, such as dry cereal, crackers, and cookies.

Place food directly between gums and molars—This will help stimulate chewing.

Cut food into strips—Use foods such as cooked carrots, fishsticks, and cold cuts, and place them on the biting surfaces to teach chewing.

Wrap cooked meat or fruit in gauze attached to a string—This prevents swallowing but gets the client to practice chewing.

Place finger food on the center of the tongue—Press down to encourage tongue lateralization. Finger food also may be placed on the nonpreferred side.

Place a cup on the baby's lower lip—Use downward pressure while controlling the flow of liquid to encourage cup feeding; thicken liquids with cereal at first, if necessary.

forms, such as canonical syllables. So encouraging parents to engage in higher-than-normal levels of back-and-forth babbling play, can increase the frequency and maturity of infant sound production. McGowan et al. (1993) suggested using rattles, tickling games, and mirrors to elicit infant vocalization in these back-and-forth games. For any baby with deficits in vocal development, all family members can be encouraged to talk “baby talk” to the baby as often as possible. If family members are uncomfortable with or not proficient in baby talk, the clinician can teach baby-talk register—including high-pitched speech; exaggerated intonation; simple words; and short, repetitive sentences—directly through modeling. Alternatively, some of the parent education sources discussed in the next section can be used.

Hearing Conservation and Aural Habilitation

It is important to monitor hearing closely in the high-risk infant. Hearing should be evaluated by an audiologist every 3 to 6 months during the first year. Furthermore, parents should be counseled to be aware of signs of otitis media, such as pulling on the ear or jaw, fever, or unexplained fussiness accompanying a cold. They should be encouraged to have the baby visit the pediatrician if any of these signs occur so that otitis media can be treated early and aggressively. For infants with identified hearing impairments, use and maintenance of hearing aids is, of course, crucial to optimal communicative development. Some of these children will be candidates for cochlear implants. According to Chute and Nevins (2003) and Papsin & Gordon (2007), good candidates for cochlear implants are children who meet the following criteria:

- Are at least 8 to 12 months of age;
- Have profound hearing loss in both ears;
- Can receive little or no useful benefit from hearing aids;
- Have no other medical conditions that would make the surgery risky;
- Have families who are involved in all aspects of the informed consent process, understand their roles in successful use of cochlear implants, have realistic expectations for cochlear implant use and are willing to be involved in intensive rehabilitation services;
- Have support from their educational program to emphasize the development of auditory skills.

Research has demonstrated that, for children with appropriate candidate status, cochlear implantation before 2 years of age promotes the efficient acquisition of expressive language (Ertmer et al., 2002), as well as receptive language and speech intelligibility (Peng, Spencer, & Tomblin, 2004). Some studies suggest that these children’s language development approximates the normal rate (Ertmer, Strong, & Sadagopan, 2003). For these reasons, it is important that SLPs discuss implantation with families of young children with severe hearing losses. Detailed information on cochlear implants can be obtained from ASHA’s (2004b) *Technical Report on Cochlear Implants*.

Child Behavior and Development

Assessment

For many high-risk infants, the management plan contains ongoing follow-up assessment of behavior and development. For some babies, ongoing assessment is the sole component of the intervention.

When we assess infant development we need to remember, again, that the goal is not to predict future status but only to identify current strengths and needs. A variety of instruments are available for assessing early development. The *Bayley Scales of Infant Development—III* (Bayley, 2005) and the *Mullen Scales of Early Learning* (Mullen, 1995) are perhaps most widely used. These scales sample behavior in several domains: cognitive, language, motor, social-emotional, and adaptive behavior on the *Bayley*, and verbal, nonverbal, and motor on the *Mullen*. Infants can receive credit for behaviors observed directly or reported by parents. The *Vineland Adaptive Behavior Scales—II* (Sparrow, Cicchetti, & Balla, 2005), a parent-interview instrument, can be used with children from birth to assess communicative, social, self-help, and motor development areas. Areas identified in the assessment can be used to develop intervention plans that are suggested in the expanded form of the interview. The *Denver II* (Frankenburg et al., 1990) is a direct assessment often used by pediatricians in their offices to assess development. The WILSTAAR screener (Alston & James-Roberts, 2005; Ward, 1999) is another instrument with some potential for this purpose. A more comprehensive list of infant assessment instruments appears in [Appendix 6-3](#). In addition to general developmental assessment instruments, several instruments are designed to look more specifically at early communicative and vocal behavior. A sampling of these is presented in [Table 6-3](#).

Any of these instruments can be used to get a picture of where the child is functioning in terms of general and communicative development. For children whose general developmental level or level of communication appears to be behind what would be expected for chronological age (or for corrected gestational age in the case of premature babies), a general stimulation program to enhance motor and cognitive development may be initiated. Such a program would be implemented in collaboration with a team of professionals that might include a physical therapist, occupational therapist, special educator, and nurse.

Parent interviews provide useful information about infant communication and development.

TABLE 6-3 A Sample of Language Assessment Tools for Infants in the Prelinguistic Period

Title	Comments
<i>Assessing Linguistic Behavior</i> (ALB) (Olswang, Stoel-Gammon, Coggins, & Carpenter, 1987)	Ages birth to 2 yr; observational and structured scales; includes assessment in cognitive antecedents, play, communicative intention, language production, and comprehension
<i>Assessment, Evaluation, and Programming System for Infants and Children</i> (ed. 2) (Bricker, 2002)	Criterion-referenced assessment, evaluation and family participation components; measures abilities in the following areas: fine and gross motor skills, adaptive, cognitive, and social communication development; also includes a Family Report Measure for parents to assess their children.
<i>Birth to Three Assessment and Intervention System</i> (ed. 2) (Ammer & Bangs, 2000)	Comprehensive program that allows examiners to identify, measure, and address developmental delays; includes a norm-referenced screening test and a criterion-referenced checklist; measures receptive and expressive language, avenues for learning, social-emotional development and motor ability.
<i>British Picture Vocabulary Scale—2nd Edition</i> (BPVS II) (Dunn, Dunn, Whetton, & Burley, 1997)	Quick, easy measure to assess a child's understanding of English vocabulary; individually administered picture-based test of receptive vocabulary; does not require reading, writing, or spelling.
<i>Clinical Linguistic and Auditory Milestone Scale</i> (Capute, Palmer, Shapiro, Wachtel, Schmidt, & Ross, 1986)	Assessment of behaviors and infant communication skills
<i>Communication and Symbolic Behavior Scale</i> (CSBS) (Wetherby & Prizant, 1993)	Used to provide early identification of children at risk for having or developing communication impairment; examines and measures communication, social-affective, and symbolic abilities; results are used to monitor changes in behavior and plan treatment.
<i>Early Language Milestones Scale</i> (ed. 2) (Coplan, 1993)	Assesses auditory, receptive language, expressive language, and visual skills and development; passing criterion for this test is noted as liberal, and failure of this test is recognized as severe impairment.
<i>MacArthur-Bates Communicative Development Inventories</i> (Fenson, Dale, Reznick, Thal, Bates, Hartung, Pethick, & Reilly, 1993)	Parent-report instruments used to determine child's comprehension and production vocabularies for children using words and gestures, and production vocabulary for children using word combinations; assessment of early child language from first nonverbal gestural signals through expansion of early vocabulary and the beginning of grammar.
<i>Pediatric Language Acquisition Screening Tool for Early Referral—Revised</i> (Shulman & Sherman, 1996)	Designed to identify potential communication problems in at-risk children; uses parent report.
<i>Receptive-Expressive Emergent Language Scale—3rd Edition</i> (REEL-3) (Bzoch, League, & Brown, 2003)	Designed to identify major receptive and expressive language problems in infants and toddlers.
<i>Rossetti Infant and Toddler Language Scale</i> (Rossetti, 1990)	Developed for birth to 3-year-olds; includes parent questionnaire and test protocol to gather observed, elicited, and parent-report information; areas assessed include play, interaction-attachment, gesture, pragmatics, language comprehension and expression; also includes questionnaire and addresses parental concerns regarding interaction and communication development.
<i>Sequenced Inventory of Communicative Development—Revised</i> (SICD-R) (Hedrick, Prather, & Tobin, 1995)	Designed to evaluate expressive and receptive communication abilities of children with and without retardation who are functioning between 4 mo and 4 yr of age; SICD-R can also be used in remedial programming for children with language disorders, mental retardation, and specific language problems.

Management

The management of behavior and development is, again, a team effort focused on the family as well as the child. Some localities provide center-based infant stimulation programs that place the baby in a setting with other handicapped or at-risk infants. These programs provide general motor and cognitive stimulation as well as more specialized services designed to target small motor, fine motor, and oral-motor behavior. When these programs are used, the SLP may be called upon to develop a plan for oral-motor and feeding development, including some of the elements already discussed, as well as to provide communicative intervention, which focuses on the interaction patterns discussed in the next section.

Most services for infants at this stage will be home-based, however. Rossetti (2001) discussed the efficacy of home-based

treatment for infants and reported the Infant Health and Development Project finding that highly positive outcomes result from this model. When services are home-based the SLP will, again, be a member of a team providing counseling and advice to the parents of the at-risk infant. When the team uses an interdisciplinary or multidisciplinary approach, SLPs may visit homes themselves and provide direct consultation to families. In settings using a transdisciplinary model, the SLP may provide information to another professional who will work directly with the family to implement the SLP's plan. Either way, the SLP can play an important role in emphasizing the relatedness of motor, cognitive, and communicative development. The language pathologist can stress to the parents that all the activities the other specialists suggest should be presented in the context of back-and-forth, warm, affectionate

communication. If this communicative aspect of the intervention is lost, it can become a lifeless exercise for both parents and child. The SLP can help to remind everyone on the team, parents and professionals alike, that babies develop within the context of human communication and that this communication is what makes entrance into the human community possible.

Another important function the SLP can fulfill in the home-based interdisciplinary program for the at-risk infant is to serve as coordinator and parent advocate. The team approach provides a broad range of expertise to the family. It also can mean that the family must deal with a lot of different people, each with a different personality and style and each offering different advice. Imagine how a new mother of a handicapped or at-risk baby must feel in this situation. She's just brought her sick baby home from the hospital. The physical therapist visits her and tells her to do exercises with the baby. The nurse tells her to be sure to give the baby medication on time. The occupational therapist tells her to position the baby a certain way for feeding. The physician has told her to watch for a set of danger signs. She's worried and frightened and wonders how she can follow everyone's prescriptions and still care for her other children, manage her household, and do whatever else she did before the baby came. The multitude of professionals inundating her with advice and assignments can be overwhelming, especially in a situation already fraught with worry.

SLPs can take on the role of putting this all in context. We can help the parents sort through the advice; decide on an overall schedule for delivering therapy and medication to the baby; and help the mother seek support from her network of resources, including family, neighbors, and friends, to get her through the difficult first few months. Most importantly, perhaps, the SLP can remind the mother that what the baby needs most is the same thing every other baby needs—to be loved and played with. Furthermore, the baby needs a family that is healthy and rested. If that means skipping the baby's exercises once in a while so that the mother can take a nap, there is always tomorrow. The SLP's awareness of the importance of effective communication as the basis of the baby's development can help us to integrate the information the family receives about their at-risk baby and to put it in perspective. In a transdisciplinary team setting, the SLP can emphasize this perspective to team members and encourage the case manager to communicate it to the family.

Parent-Child Communication

Assessment

The *Parent-Infant Relationships Global Assessment Scale* (Aoki, Iseharashi, Heller, & Bakshi, 2002), the *Parent Behavior Progression* (Bromwich et al., 1981), and the *Observation of Communicative Interaction* (Klein & Briggs, 1987) were discussed earlier as means of assessing parent-child interactions. The *Parent-Child Play Scale* (Dunst, 1986a), the *Parent-Child Interaction Scale* (Farran, Kasari, & Jay, 1983), and the *Caregiver Styles of Interaction Scale* (Dunst, 1986b) are additional instruments that can be used to rate parental communication. These are somewhat formalized means of looking at how parents interact with the young baby who is not yet initiating much communication but is beginning to be able to respond consistently to the interactions of the family.

Parent-child interaction can be assessed informally, too. When observing parents interacting with their at-risk babies, we can look for the following:

1. Pleasure and positive affect.
2. Responsiveness to the child's cues of readiness and unreadiness to interact.
3. Acceptance of the baby's overall style and temperament.
4. Reciprocity and mutuality—the degree to which the parent and infant seem to be in tune with each other.
5. Appropriateness of choice of objects and activities for interactions; the parent's awareness of safety issues and choice of activities and objects that interest and engage the baby.
6. Language stimulation and responsiveness; the degree to which the mother talks to the baby appropriately, engages in back-and-forth and “choral” babbling activities.
7. Encouragement of joint attention and scaffolding the baby's participation, the extent to which the mother is effective in directing the baby's attention to objects of mutual interest, and the ways she evokes progressively more elaborated responses from the baby.

Establishing which aspects of parent-child interaction can be improved will serve as the basis for the intervention program designed to facilitate parent-infant communication. It is crucial to remember, though, that when assessing parent-child interaction patterns, we must show respect and appreciation of the parent's attempts to get through to the child. If we behave as if we know better than the parents how to interact with this baby, we will be undermining rather than supporting them.

And it is important to know, as Whitehurst et al. (1988) pointed out, that even normal parent-child interactions may not be optimal. In other words, it is always possible to intensify and increase the frequency of parental input, even when the parent is doing everything right. The stance we want to project to the parents of a handicapped or at-risk infant is that of maximizing the parents' effectiveness, rather than correcting their mistakes. We want the parents to feel that they are partners in providing an enhanced communicative environment for their child and that we are simply making some suggestions for that enhancement. Using data from the assessment of parent-child interactions can help us to identify *with the parent* the aspects of the interaction that can be enhanced. This approach is greatly preferable to using the assessment to identify what the parent is doing wrong. Everything we discussed in the newborn section about the dangers of formal assessment of parent-child communication and family function applies to the older baby, too.

Management

Intervention in the area of parent-infant communication, in either a home- or center-based setting, involves three components. First, we need to make parents and other caregivers aware of the normal communicative patterns of infants and how to tune in to the baby's communicative capacities. Second, we need to provide instruction and modeling of adult-infant communication. Third, we need to help the parents develop self-monitoring skills so that they can evaluate and modify their own performance.

Awareness of Infant Communication Patterns

Communication with babies is a two-way street. Mothers tend to interact more frequently with and respond more consistently to babies who smile and vocalize at them more often (Clarke-Stewart, 1977; Rossetti, 2001). So if a parent seems unresponsive to the baby, our first task is to remind ourselves that the mother's earlier communicative attempts may have been extinguished by a lack of consistent response from the child. Communication may have to be reinvigorated, no matter whose behavior is extinguishing whose. But we should refrain from being too quick to blame the parent for the dyad's failure to achieve optimal communication. Parents are more likely to cooperate if they feel that we understand the difficulties of communicating with an at-risk baby, who may not be normally responsive and interactive. If the parents feel they

are being blamed for the child's problem, collaboration is more difficult.

Remember, too, that we don't always have to say out loud that we blame the parents. Even unspoken censure can be perceived by parents. However, by reassuring the parent explicitly and repeatedly that we know that communicating with this baby can be hard, we can protect against the potential of this unspoken disapproval to interfere with our relationship with the parent. By acknowledging the difficulty of communicating with the child, we tell parents that we know they are not to blame, that the child participates in forming the quality of the interaction, that it takes two to tango. With this acknowledgment, we can get on cooperatively with the difficult job of providing a mutually positive communicative environment for the parent and child.

Helping parents become aware of basic interactive patterns of preintentional infants can be part of a general program of parent education, involving direct instruction about infant development and directed observation of videotapes or live interactions between infants and caregivers. Many parent education materials, including videotapes, are available for this purpose. Some of these are listed in [Appendix 6-7](#) and [6-8](#). Parent education also can be a more circumscribed exercise, in which the SLP provides information specifically about communication to the infant's family. Either way, we want parents to know several things about how babies communicate. First, we want them to know that, although the infant participates in structuring the interaction, the infant—because of his or her immaturity—has very little choice about how to interact. The infant is not choosing to be difficult or consciously rejecting the parents' advances. Infants are simply expressing their inborn style, as well as their physiological and neurological immaturity in these behaviors. The preintentional infant does not “mean” to be naughty. The parent, though, as a mature adult, has choices. Parents need to know that they are the ones who need to adapt for the interaction to succeed, even when it is the infant who is causing the problem by being difficult or unresponsive.

Second, the parents need to know that the most important thing they can do for their babies is to enjoy them. Whatever they and the baby like to do together is what constitutes an ideal interactive context. If they enjoy making silly faces or funny noises or swinging the baby around, these activities should be encouraged.

SLPs can help parents become aware of interactive patterns of preintentional infants.

Similarly, if the baby's siblings like jostling the baby and the baby giggles and coos, these activities, too, should be fostered, even if they make the parents a little nervous. A bit of extra watchfulness, rather than a prohibition on these sibling interactions, may be needed.

The third thing we want parents to know is that communication that enhances development has two major characteristics: it is *enriching* and *responsive* (Clarke-Stewart, 1973; Poehlmann & Fiese, 2001). This means that as they interact with their high-risk babies, parents should think about providing visual, auditory, and tactile experiences that engage the baby's attention and allow the child to explore novel stimuli that have been carefully chosen for safety and interest. They also should attempt to make their interactions responsive to and contingent on what the infant is doing. This involves needing to tune in to the baby to observe and learn to recognize the baby's signals of need for attention and readiness for interaction. Some parents may need to be educated about the impossibility of “spoiling” the preintentional infant. Parents need to know that being consistently responsive to the infant's cries and moods at this stage can only enhance development.

Modeling Interactive Behaviors

Four types of interactive behaviors should be encouraged in parents to foster communication with their infants. These are: *turn-taking*, *imitation*, *establishing joint attention*, and *developing anticipatory sets*. Gazdag and Warren (2000) showed that adult contingent vocal imitation, particularly, increased the amount of imitation produced by babies with developmental disabilities. These behaviors can first be observed by the parents, using videotapes if they are available. If not, the clinician can provide models directly.

Effective modeling of turn-taking, imitation, and establishing joint attention and anticipatory sets involves, first, being sure that the parent is sensitive to the infant's readiness to interact. It will not be possible to set aside a particular time of day for these activities. The parent must be prepared to engage in them whenever the infant signals readiness through a state of alertness, gaze at the parent, and the expression of comfort vocalizations. When these signals are perceived, the interactions should be initiated. So it is important to be sure parents can recognize and respond to these signs when they occur. Parents should be reminded that these signals can come at any time—during meals, diapering, at bath time, or during a myriad of ordinary daily living routines. Parents can be encouraged to take advantage of the baby's alertness whenever they observe it and can be helped to learn to integrate ordinary caretaking activities with interactive stimulation.

Once parents can recognize the baby's readiness to interact, the four aspects of interaction can be modeled by the clinician. We can use the acronym TIPS to help with this modeling ([Box 6-4](#)). To model *turn-taking* and *imitation*, we can demonstrate observing the infant; using smiles and vocalization to elicit infant behavior; and waiting while the infant performs some behavior, whether it be vocalizing, moving the limbs, or making a face. Once the infant does something, the clinician can imitate it, then wait for the infant to do something else. MacDonald's ECO program (see [Appendix 6-7](#)) for example, encourages parents to use a “match and wait” strategy in developing turn-taking and imitation skills. Parents are advised to imitate or “match” something the child does, then wait for the child to provide a response that the parent can “match” again. The parent can be encouraged to try this turn-taking and imitation while the infant remains in an alert state. Vocalization to the infant and imitation of infant vocalization should be particularly encouraged, since

BOX 6-4 TIPS for Working with Parents of Preintentional Infants to Optimize Parent-Child Communication

- T: Take turns:** Coach parents to engage in back-and-forth interactions with babies through songs, games such as peek-a-boo, and play with toys. Encourage parents to do something the baby enjoys, then wait for the child to do something (anything!) before the adult takes another turn.
- I: Imitate:** Coach families to play “monkey see, monkey do” or “copy cat” by mirroring any infant actions or sounds.
- P: Point things out:** coach families to engage the baby in joint attention routines by bringing things the child likes within view, and monitoring that the child is looking at them before making them move, sound, or operate. Later, when the child is 6 to 10 months old, use gestural pointing to establish joint attention to objects at a distance in addition to bringing objects near the child.
- S: Set the stage:** Coach parents to establish anticipatory sets by repeating simple games and songs the child likes. When the child has become very familiar with these, encourage parents to stop momentarily in the middle to allow the child to anticipate and request the next part of the action.

these are especially helpful techniques for encouraging infant vocal development.

In addition to fostering turn-taking and imitation skills, it is important to help parents learn to develop *joint attentional routines* with their babies. Bruner (1981) emphasized the importance of establishing joint attention to help the baby learn to share focus on a topic and elaborate on it. This ability to share a topic and make additional comments upon it lays the basis for the topic-comment structure of mature conversation, in which a shared topic is established, then elaborated by additional comments from the participants.

The establishment of joint attention can begin by modeling for the parent how to identify the infant's focus and share attention to that. The clinician can show the parent how to follow the infant's line of regard, look at what he or she is looking at, and then make a comment about it or a gesture toward it. For example, we can demonstrate looking at the baby's hands as the baby focuses on them. We can then say, “Hands. You have such little hands!” and gently stroke them as the baby continues to regard them. If the baby's gaze then shifts to the clinician's face, we can return the gaze and remark, “I see you, too!” The clinician can then introduce an attractive toy and demonstrate showing it to the baby to engage his or her attention. When the baby looks at it or reaches for it, the clinician can demonstrate commenting on it or using it in a new way. In this way the clinician can model establishing joint attentional activities with the infant. “Choral” vocalization, saying what the infant says at the same time he or she says it, as if singing together, also can be encouraged as a joint attentional activity.

Another joint attentional activity that can be fostered is the use of baby games. These games also are useful in *establishing anticipatory sets*. Anticipatory sets are expectations that actions that have been repeated often for the baby will occur in a particular sequence, so that the infant “gets ready” to observe them when part of the sequence is enacted. These anticipatory sets provide the baby with predictable series of sound and action that lay the basis for the development of knowledge of scripts or schemata. It is thought that these scripts help organize knowledge and the acquisition of language used to encode this knowledge (see Milosky, 1990, for further discussion). “Peek-a-boo,” “gonna getcha,” and other games that foster predictable series of actions and words are especially useful in laying the groundwork in this process. By observing the parent repeatedly reenact the same actions using the same words, the infant learns to anticipate the climax of the routine. This pleasurable anticipation not only intensifies the baby's interest in the joint action, but also heightens awareness of the

sequence, making it more salient and “learnable.” Once the baby learns the routine as a script, it becomes available for the child to manipulate, as when, for example, the child spontaneously uses an action in the routine as a request for the parent to play the game. Predictable joint action sequences also foster in the baby a sense of trust and reliability, a feeling of knowing what can be expected from people. This sense has obvious consequences for socioemotional development, but it has consequences for communication, too. A child who feels others are dependable and predictable, particularly if they are predictable in providing fun and interesting things for the baby to see and do, is more likely to think that communicating with these people is worthwhile and worth the effort to learn.

It is important for the clinician to determine which games are culturally appropriate for the family. Not all cultures play “peek-a-boo” exactly the same way, and each culture has its own set of baby games that the parents learned from their own parents. The family should be encouraged to recall and to ask older family members if they recall what baby games are traditionally used. These games will have the greatest affective value for the parent and so are likely to be more engaging for the child than games taught by the clinician. If the family is really unable to come up with games that have been used traditionally in their social group, only then should the clinician offer to introduce baby games from the mainstream culture.

Developing Self-Monitoring Skills

Once parents have learned the basics of communication development in the preintentional infant and have had the opportunity to observe the clinician demonstrate appropriate interactive techniques, they need to develop confidence in their own ability to communicate with the baby. One very effective way to achieve this result is through the use of videorecording to monitor communicative interactions and allow the parent to self-monitor. If videorecording equipment is available, parents can be encouraged to interact with their babies, and later, when the baby is no longer alert, review the recording to observe themselves with the baby.

The clinician must be very careful to do this training in a non-threatening atmosphere. It is essential to give the parent a feeling of acceptance and safety. Doing so requires establishing an atmosphere in which both the clinician and parent are attempting to learn about what works best with this baby, rather than one in which the clinician is dictating, or even teaching behavior to the parent. In this accepting atmosphere, parents can learn to observe their own and the baby's behavior, determine whether they have

made a good match between the two, and develop strategies for assessing the effectiveness of the interactions and modifying them when necessary. Allowing parents to view videos and analyze their own performance, rather than having it analyzed by the clinician, can facilitate this process. The clinician can comment on the positive aspects of the interaction. If the parent fails to note some changes that the clinician feels should be made, the SLP can ask the parent how the interaction might be conducted differently or whether there were any times when the baby seemed to be unresponsive. These episodes of unresponsiveness can be used as a springboard for discussing how the interaction might have been made more effective.

After several video sessions, parents will probably benefit from watching a recording of the earliest interactions. They can observe how much the baby has grown, as well as how their own interactions have changed and become more attuned to the child. The clinician can use these occasions to praise and appreciate the efforts the parents have made. The development of confidence in their own ability to do what is best for the baby is what will encourage parents to further progress in providing an optimal environment for their child's growth. The *Hanen Early Language Parent Program* (Girolametto, Greenberg, & Manolson, 1986) is one commercially available program that incorporates many of these principles we've been discussing. Other programs include MacDonald's (1989) ECO program, Bricker's (2002) system, and the *Carolina Curriculum for Infants and Toddlers with Special Needs* (Johnson-Martin, Hacker, & Attermeier, 2004). Additional resources can be found in [Appendix 6-7](#).

ASSESSMENT AND INTERVENTION FOR INFANTS AT PRELINGUISTIC STAGES OF COMMUNICATION: 9 TO 18 MONTHS

In the last quarter of the first year of life, infants undergo an important transition. They move from being participants in interactions to being intentional communicators. Children in this developmental stage, in Halliday's (1975) terms, "learn how to mean." In Bates's (1976) parlance, these children are in the *illocutionary* stage of communication, when they express intentions through signals to others but do not yet use conventional language. At this level, children need interactions that both acknowledge and enhance their growing understanding of the functions and meanings of communication. The techniques used in the preintentional period to evaluate and encourage vocal and oral-motor development, as well as those for assessing and enhancing general cognitive growth and monitoring hearing, are still applicable to the prelinguistic communicator. However, the needs of the child in the 9- to 18-month developmental level will change in terms of the types of communicative interactions that will best foster development. It is important to remember that we are talking about children whose *developmental* level is 9 to 18 months. For children with a history of prematurity, CGA will still determine expectations for performance at this stage. Ten months after Janice's birth, for example, her CGA would be 8 months (40 weeks CA minus 8 weeks prematurity), and she would not be considered delayed if intentional communicative behavior had not yet emerged. Other children with disabilities who are 9 to 18 months old chronologically also may remain in the preintentional stage of development for some time. When cognitive assessment suggests that this is the case for children in the first 2 years of life, intervention should

continue at the preintentional level. Only when a toddler evidences through play and other behavior that intentionality is emerging should the intervention begin to "up the ante," to require more initiation of communication and more conventional forms of communicative behavior from the child.

Assessment

How do we know that the infant has made this transition to intentionality? This question can be answered either formally or informally. The formal assessment procedures listed in [Appendix 6-3](#) can be used for the older infant. When the child achieves a developmental level of 9 to 10 months or more on one of these instruments, readiness for intentional behavior can be inferred.

Intentionality also can be assessed through observation of the child's play. This can be done using one of the formal play assessments listed in Chapter 2, such as the *Symbolic Play Test* (Lowe & Costello, 1976), Carpenter's (1987) *Play Scale*, Casby's (2003) *Developmental Assessment of Play*, or the *Communication and Symbolic Behavior Scales* (Wetherby & Prizant, 2003). It also can be done informally, by providing the child with common objects that invite conventional and pretend play, such as dolls, child-sized common utensils, and familiar household objects. The observation can be used to determine whether the child is demonstrating some recognition of common objects and their uses, such as using a comb to comb hair or putting a toy telephone to the ear, and can engage in simple pretend play schemes, such as pretending to eat from an empty spoon. More detailed information on informal play assessment is provided in Chapter 7. If these conventional uses of objects and early representational behaviors are observed during the play session, the clinician can be confident that the child is ready to engage in intentional communication.

Alternatively, we can use a parent-report instrument to elicit information about early communicative behavior. The Words and Gestures form of the *Communicative Development Inventory* (Fenson et al., 1993), for example, provides a checklist that parents can fill out to answer questions about early communicative and symbolic gestural production. The *Vineland Adaptive Behavior Scales—II* (Sparrow, Cicchetti, & Balla, 2005) also contains items on play development. This information, too, can be used to help determine whether the child is demonstrating behaviors that imply intentionality.

If intentional behaviors are neither observed nor reported, the clinician can attempt to elicit them by modeling conventional use of objects and engagement in simple pretend schemes and observing whether the infant can use the models in his or her own play. If the infant can produce these behaviors in response to a model, some intentionality is likely to be present and the infant could probably benefit from intervention focused on eliciting intentional communication. At least it can't hurt to try. If repeated attempts to elicit conventional and early pretend play do not succeed, however, the clinician may decide to postpone moving to a program for eliciting intentional communication. Instead, we can continue to encourage the parents to engage in turn-taking, imitation, building anticipatory sets, and joint attentional activities in their interactions with the baby, and we can look for evidence of intentional behavior as time progresses.

Once it has been established that the infant can benefit from a program focused on intentional communication, assessment may be useful in determining the frequency and types of communication that the baby is demonstrating. The *Communication and*

Symbolic Behavior Scales (Wetherby & Prizant, 2003) is a formal instrument for assessing infant and toddler communication skills. This procedure involves videorecording the baby engaged in play interaction and using a standard format for examining the child's means of communicating, speech production capacity, receptive language, and related cognitive abilities and social-affective behavior. Paul (1991b) provided a less formalized approach that uses direct observation rather than videorecording to examine intentional communication. We will discuss procedures for assessing early intentional communication in detail in Chapter 7.

The point of assessing communicative behavior in the child with a developmental level of 9 to 18 months is simply to determine whether any functional communication is present. When the intentional underpinnings, as evidenced by the appearance of conventional and early pretend play, are observed in children at this level, functional communication should begin to enter their behavioral repertoire. We simply want to find out whether a play interaction with a familiar adult elicits any communicative behaviors, whether they are gestural, vocal, or verbal. We also would like to know what kinds of intentions are being expressed. Typical functions expressed at this level include requesting objects or actions; attempting to get the adult's attention on what the child is interested in; and initiating social interactions through greeting, calling, or showing off. If any intentional communication on the child's part is observed, we can infer that a child in the 9- to 18-month developmental range is progressing adequately. If intentional communication does not appear to be present in a child functioning at a 9- to 18-month level and parents confirm that the child's behavior during the observation was typical, we can infer that communication development is beginning to lag.

Management

If the child's communication development does seem on target, this does *not* imply that we can stop providing advice or support to the family of an at-risk infant. On the contrary, we want to foster the communication the child is showing, and primary and secondary prevention of later language disorders is still our main concern. For the at-risk child at a 9- to 18-month developmental level who is expressing some communicative intent, we need to encourage parents to learn how to scaffold or support the child's move toward more conventional communication. Brady, Marquis, Fleming, and McLean (2004) showed that parent responsiveness is a significant predictor of language development in children with disabilities. "Upping the ante" is Bruner's (1981) term for the techniques parents normally use to elicit a higher level of response from a child, once a response of some kind has been evoked.

For example, suppose a baby at a developmental level of 9 to 18 months has been playing peek-a-boo for some time with his mother, consistently showing joint attention to her when she covers her face to start the game and demonstrating anticipation of her revealing her face again. The mother can "up the ante" by keeping her face covered until the child does something. At first, she can keep her face covered until he reaches up and pulls her hands away. When the baby does this consistently, she can refuse to move her hands until he vocalizes along with his reaching toward her. By requiring increasingly more mature and sophisticated behaviors on the baby's part to complete the routine, the mother is shaping his behavioral repertoire to include more conventional ways of expressing his intents.

Rossetti (2001) suggested helping parents of infants in this stage to demonstrate contingent relations between words and

actions. For example, parents can be asked to produce a verbal accompaniment to their response to a child's signal to be picked up. They can say, "Up!" when they pick up the child in response to the child's raising arms as a signal. Rossetti also encouraged teaching parents to amply reward any gesture or vocalization used as a communicative signal during this stage.

Warren and Yoder (1998) advocate the use of *prelinguistic milieu teaching (PMT)* to help in making the transition to intentional behavior. You may remember that we discussed milieu teaching as one of the hybrid forms of intervention in Chapter 3. In the prelinguistic period, it involves, first, arranging the environment by putting things the child will want in view but out of reach or by violating the order of events the child has come to expect. So we might put a new stuffed animal on a shelf where the child cannot reach it or offer the child juice before we have given a cup. The next step is to follow the child's attentional lead and focus on the child's item of focus. If the child looks at the new stuffed animal, we can look at it, too, then at the child, and wait expectantly for the child to do something (almost anything!) we can interpret as a request. Warren and Yoder stress that it is important to adapt our expectations to the child's initiation rate, which may be lower than we would like. It is more important to wait for the child to do something, then make our actions contingent on the child's, than it is to get the child to do something as a response to our own action. For children who just do not initiate, Warren and Yoder suggest two contingent strategies. *Contingent motor imitation* is an exact, reduced, or slightly expanded imitation of a child's motor act performed by the adult immediately after the child does it. *Contingent vocal imitation* occurs when the adult follows a child's vocalization with a partial, exact, or modified vocal imitation. Both these techniques allow the child to regulate the amount of social stimulation and may encourage him or her to produce more behavior for the adult to imitate.

Once the child has established some initiation of communication, Warren and Yoder suggest using some additional techniques to increase the frequency of initiation, so long as the teaching episodes are brief, positive, and embedded in ongoing natural interactions. These techniques include using three types of prompts: *time delay*, *verbal*, and *gaze intersection*. *Time-delay* prompts involve interrupting an ongoing turn-taking activity or routine and withholding the continuation until the child initiates some form of request to resume. For example, if the adult and child are rolling a

SLPs can work with parents of at-risk infants to optimize interaction for the purpose of secondary prevention.

ball back and forth, the adult can hold onto the ball during one turn, look at the child, and wait expectantly until the child does something (again, almost anything) to initiate a request to continue. *Verbal* prompts can be open-ended questions (“What?”) or directions (“Look at me”). *Gaze intersection* involves the adult’s moving into the child’s gaze when the child does not make eye contact. This prompt is gradually faded as the child begins to use eye contact more consistently for regulating interaction. Another technique is *modeling*. Models are used to increase the child’s use of vocal and gestural communication. Vocal models of sounds that the adult has heard the child use are matched to communicative events to show how vocalization can express intentions. For example, if the child has been heard to produce /ba/, the adult can use this syllable when blowing bubbles, saying /ba/, /ba/ as each bubble pops. Gestural models can be used in a similar way to encourage the child to imitate communicative actions. For example, if the child has been seen to reach for an object, the adult can point to it. An additional technique that can be used to encourage communication is *natural consequences*, in which the child’s communication is rewarded with its intended goal. If the child points to a cookie jar, the child is given a cookie (even if it is right before dinner). In addition to the natural consequence, though, the adult can provide a simple linguistic mapping (“You want a cookie!”) as well as an acknowledgment that an appropriate form of communication was used (“I can tell because you pointed. Nice job!”). Yoder and Warren (2002) showed that PMT did accelerate growth in frequency of child-initiated comments, frequency of child-initiated requests, and lexical density in some, though not all, children in an experimental study of the technique.

Book-reading situations are particularly apt settings for encouraging communication. Elliott-Templeton, Van Kleeck, Richardson, and Imholz (1992) showed that parents begin reading books to babies when the children are as young as 6 months. Snow (1983) has documented how parents of children with typical development use book-reading situations to scaffold language acquisition, and Bedrosian (1997) discussed this context for use with children with disabilities. Book-reading interactions have been shown to be effective in fostering both language and literacy development (Chomsky, 1972; Whitehurst et al., 1988). Parents of at-risk youngsters should be encouraged to begin engaging babies in looking at simple picture books as soon as the child can sit up. They can first have the babies sit with them and look at the pictures as the parent names each page with a simple label. Girolametto and Weitzman (2002) identify behaviors that can facilitate communication development in this setting, which include the following:

- Waiting for the child to initiate interest in something in the book by looking or pointing;
- Being face-to-face during book sharing;
- Asking questions;
- Verbally inviting children to interact;
- Labeling and talking about pictures in the book.

The child’s first level of response is simply to share joint attention to the pictures. Once the child has seen the book and heard it read several times, the parent can stop on one page and wait for the child to do something. If the child points to the picture, the parent can name it. Later the pointing gesture can be “upped” to a vocalization. Eventually the child will be expected to name or approximate the names of some of the pictures. Upping the ante in this way comes naturally to some parents and caregivers. They spontaneously recognize when the baby is ready to be nudged to a higher level of response or will do so readily once the clinician

points out the baby’s readiness to them. Other parents may need more explicit instruction. Yoder and Warren (2002) showed that training parents to use responsive strategies in communicative interactions does result in positive changes in their ability to respond to child communication. Again, direct modeling by the clinician, showing the parents ways to up the ante in familiar day-to-day routines and activities, is helpful. Parents should then be encouraged to follow the clinician’s example in the same routines. Monitoring, discussion of the effectiveness of the techniques, and self-monitoring using videos are, again, useful adjuncts in this enterprise.

Another technique used to foster the development of communication at this level is *communication temptations*. These involve creating situations in which the child is strongly motivated to try to get a message across to the adult and then responding swiftly and positively when the child does attempt to communicate. Warren and Yoder (1998) and Wetherby and Prizant (1989) presented some examples of communication temptations, which are listed in [Box 6-5](#). These temptations can be used to increase the frequency of communication in at-risk children and to give them practice with using intentional behavior and seeing its positive results. In these activities, the focus is not on the form of communication. Any gesture or vocalization that is clearly intended to send a message receives the desired response. Communication temptations also can be used to elicit initial communicative behaviors from children at this level who are not yet demonstrating such behavior spontaneously.

In addition to fostering the child’s expression of communicative intents, we want to provide experiences in which the child can develop comprehension of language. Rossetti (2001) suggested using baby games to pair words with gestures and referents. Parents can start out demonstrating meaning for the infant by saying, for example, “Show me your nose” and taking the baby’s hand and placing it on the nose. Later, the ante can be “upped” by having the parent say, “Show me your nose” and then waiting until the baby produces some gesture. In addition to developing communicative skills, these kinds of routines are ideal for expanding the child’s comprehension repertoire, by adding new items (eye, ear, mouth) to the game. The same modeling, monitoring, and self-monitoring techniques used to work with parents of younger babies, including use of video to facilitate self-monitoring, can be used as part of these kinds of interactions. Published programs in [Appendix 6-7](#) and [6-8](#) also can be useful at this stage.

These suggestions outline a prevention program for the at-risk child at a 9- to 18-month developmental level who appears to be developing adequately in terms of communication. What about the child who functions at a 9- to 18-month level but who has not yet evidenced intentional use of communication? We would suggest that for this child, intervention should focus on providing intensified input using a “motherese” speech style (Newman, 2003); focusing on developing comprehension skills; encouraging vocalization; and making the adult’s communication contingent on what the child does, rather than on eliciting communication just yet. Providing a responsive atmosphere and a range of models of intentional communication is, in our view, a sufficient goal at this stage. There will be time for more intensive efforts to increase the frequency and maturity of communication when the child moves on to the next developmental stage. For now, both parent and child can benefit from what enriched, contingent input has to offer: for the parent, practice in providing responsive and contingent language stimulation, and for the child, the opportunity to

BOX 6-5 Suggestions for Communication Temptations

- Eat a desirable food item in front of the child without offering any to him or her.
- Activate a wind-up toy, let it run down, then hand it to the child.
- Give the child several blocks, one at a time, to drop in a can, then give the child a small toy figure to drop in.
- Initiate a familiar game, play it until the child expresses pleasure, then wait. Look expectantly at the child, and give a prompt ("What do you want?").
- Open a jar of bubbles, blow some bubbles, then close the jar tightly, and hand it to the child.
- Blow up a balloon, and let the air out. Then hand the deflated balloon to the child.
- Hold a food item the child does not like near his or her mouth.
- Place a desired toy or food item in a clear container with a tight lid that the child cannot open. Give the child the container and wait.
- Put the child's hand in a cold, wet, or sticky substance such as pudding or paste.
- Roll a ball to the child. After several rolls back and forth, substitute a car or other wheeled toy.
- Put a toy that makes noise in an opaque bag. Shake the bag and hold it up to the child.
- Bring the child a new toy, or initiate a silly or unusual event (wear a clown nose). Wait for the child to do something. When he or she does, map the child's action onto a linguistic form ("You think my nose is silly!").
- Pay less attention than usual to the child; back away or turn your back during an ongoing game. Wait for the child to try to elicit your attention.
- Give the child the run of the room for a few minutes. Wait for the child to direct your attention to an object he or she finds of interest.

Adapted from Warren, S., and Yoder, D. (1998). Facilitating the transition from preintentional to intentional communication. In A. Wetherby, S. Warren, & J. Riechle (Eds.), *Transitions in Prelinguistic Communication* (pp. 365-384). Baltimore, MD: Paul H. Brookes; Wetherby, A., and Prizant, B. (1989). The expression of communicative intent: Assessment guidelines. *Seminars on Speech and Language*, 10, 77-91.

experience its benefits for understanding language and providing a reliable scaffold toward linguistic production. Parents and caregivers ought to be encouraged to respond consistently to any initiation on the child's part, of course, even if it is in the form of gestures or nonconventional vocalizations. Focusing on the linguistic environment seems to us to be the most sensible approach for the infant who has not yet figured out the purpose of communication. Although there are no empirical data to support this position, we offer it to you as our best clinical hunch.

Some of the activities outlined in the preceding paragraphs for the emerging communicator can certainly be tried with the 9- to 18-month-level noncommunicator as well. Book reading is clearly an appropriate activity, as are the continuation of joint attention routines and baby games, whether or not the ante gets upped in this

context. Some communication temptations can be tried to elicit intentional communication. However, if they don't elicit the desired behaviors, we advocate returning to basic joint attention activities and enriched contingent input, rather than continuing the temptations for now. They can be tried again when the developmental level moves closer to 2 years. Activities to encourage oral and vocal imitation, including imitating the child's vocal behaviors and providing simple, conventional single words in response to the baby's vocalizations, also can be suggested to parents of these reluctant communicators.

The key, in our opinion, is to keep the focus on responding to the baby's needs and interests, making the parent's communication contingent on the infant's actions, and making sure that the parents and baby are still enjoying each other. Insisting too soon on particular behaviors from infants instead of responding contingently to all their behaviors runs the risk of teaching babies the opposite of what we want them to learn. We want to teach that communication is an effective, pleasurable way to influence those around us and to exert some control over our environment. This is the message that we need to bring home to the baby who is emerging as a communicating human being. This lesson is best taught by example, by providing babies with models of communication that respond to their wants and needs.

It is never too early to encourage parents to share books with their children.

CONSIDERATIONS FOR OLDER PRELINGUISTIC CLIENTS AND THOSE WITH AUTISM SPECTRUM DISORDERS

Some clients who function at prelinguistic levels of communication are older than the infants we've been discussing. Who are these clients? Some are severely or profoundly impaired individuals with cognitive deficits that limit their ability to develop symbolic communication skills. Many of the syndromes of intellectual disability that we discussed in Chapter 4 can present this picture. Some older children with autism may function at prelinguistic levels of

communication, with very little use of words. Young hearing-impaired children who were not identified or amplified early and who did not receive early introduction to sign language can communicate at prelinguistic levels beyond the age of 18 months. Children with severe speech impairments who have not been provided with alternative forms of communication may function at this level beyond the first 2 years of life. Finally, children who suffer severe or profound acquired brain damage through trauma or disease can lose their ability to use language to communicate.

Let's clarify one important distinction, though. A child can be nonspeaking yet still be a linguistic communicator. Children with cerebral palsy, for example, may be unable to speak because of neuromotor difficulties but can communicate linguistically through spelling on a communication board with a headlight or by means of an electronic device that prints out or speaks messages the client creates on a keyboard. These children with severe speech production impairments were discussed in Chapter 4. In this section we are concerned with children who have deficits that extend beyond the neuromotor act of speaking to include limitations in the ability to understand and use words or symbols to communicate. These children, who function within the first 2 years of cognitive development, are considered *prelinguistic* communicators. Let's examine the same issues for this group of clients that we looked at for prelinguistic infants: feeding and oral-motor development, hearing conservation and aural habilitation, behavior and development, and communication.

Feeding and Oral-Motor Development in Older Prelinguistic Clients

Many older children with prelinguistic communication skills have difficulties feeding because of neuromotor involvement. For these children, feeding and swallowing issues clearly need to be addressed. Although an in-depth discussion of feeding and swallowing is beyond the scope of this text, many of the references cited earlier for use with infants in these areas also are useful for addressing feeding issues in older clients. ASHA (2010) discussed the role of SLPs in pediatric feeding, and Claude and Bernard (2006) provided an evidence-based review and practice guidelines for feeding infants and toddlers. McNeilly & Sheppard (2008) provide an extensive discussion of dysphagia treatment in school settings. Arvedson (2008) and Bailey and Angell (2008) provide additional guidelines for SLPs working in schools. Abraham (2003) and McGowan and Kerwin (1993) discussed these issues in detail for children with long-term tracheostomies, with suggestions that can apply to children with a variety of types of feeding disorders. Alexander (2001), Bricker (2002), Eicher (2007), and Hall et al. (1987) provided discussions of feeding issues for children with neuromuscular disorders that are helpful in working with parents on developing children's feeding skills. [Box 6-3](#) and [Appendix 6-6](#) summarize some of the suggestions of these writers. Pressman and Berkowitz (2003) emphasize that before initiating a feeding program, any associated medical problems must be addressed. Arvedson (2000) provides comprehensive guidelines for conducting the major portions of the evaluation of children with feeding and swallowing disorders, which include the following:

- Review of medical, developmental, and feeding history.
- Physical examination, including growth and nutrition, neurodevelopmental, oral-facial, cranial nerve, respiratory, and gastrointestinal elements.
- Prefeeding assessments, such as posture and position,

oral-motor structure and function, and social and affective aspects of feeding.

- Direct observations of chewing, biting, swallowing, and interactions during feeding.
- Assessment of food preferences.
- Deciding whether to employ instrumental assessments, such as the videofluoroscopic swallow study.

Bailey and Angell (2008) suggest that feeding issues, like others, can often be addressed with behavioral approaches, involving new skill acquisition, generalization, and reinforcement. In addition, Jaffe (1989) and Lowman, Murphy, and Snell (1999) are careful to point out the importance of helping parents learn not only the physical skills involved in feeding a child with a disability, but also of emphasizing the communicative aspects of feeding. Eating is a social experience; a pleasant, interactive atmosphere is essential to developing a good feeling about food and eating. If the parent (or therapist) treats eating as a mechanical exercise, this crucial social component can be lost. As a result, both child and parent may come to see eating as a purely biological function, rather than an event in which people participate and interact. Hall et al. (1987) suggested that parents be encouraged to maintain a pleasant, positive facial expression and voice during feeding; that they give lots of praise and verbal encouragement; and that they speak to children during feeding, being careful to time remarks so that they don't excite abnormal patterns of chewing or swallowing. For older children in school programs, developing social opportunities during eating times also is important. Morris (1981) suggested setting up "lunch clubs" for children with feeding problems. These would give the child with a disability the opportunity to eat with small groups of mainstream children, who are chosen as a special privilege, to eat with the client in a special place (such as a classroom or teachers' room), perhaps on a rotating basis. This approach provides social opportunities and reduces the distractions present in a large cafeteria. Lowman, Murphy, and Snell (1999) and Bailey, Stoner, Angell, and Fetzer (2008) provide additional discussion. And because food is so deeply embedded within culture, SLPs need to be aware of and sensitive to the attitudes of families about feeding (Davis-McFarland, 2008).

Hall et al. (1987) emphasized the role of developing feeding skills as a foundation for vocalization and speech. As Ruscello (2008) pointed out, though, it is important to be aware that oral-motor skills such as those used in feeding are necessary, but not sufficient, for learning to talk. Steeve and Moore (2009), for example, showed that mandibular control and coordination for babble and chewing or jaw oscillation were categorically different in infants, and that independent sets of coordinations underlie the two activities. Morris (1981) found that many children who make gains in oral-motor skills do not necessarily translate these skills into speech production. In other words, developing oral-motor skills through feeding is important because eating is important, but it will not guarantee that these skills will generalize to speech. To develop speech skills, speech must be addressed directly in an intervention program. We cannot assume that work on the vegetative function of eating will ensure the development of the voluntary function of speech.

For prelinguistic preschoolers, then, it makes sense to address vocal production explicitly as part of the intervention program. Several approaches are available. Ling (1976) developed a sequenced approach to acquiring vocal skills that was designed for children with impaired hearing but can be adapted for children with other types of impairments. Hayden (1984) advocates the use

of a program of tactile stimulation, derived from work with adults with apraxia, the PROMPT program, although little empirical evidence of its efficacy exists. Since Yoder and Warren (2002) found that production of canonical (CV) syllables was predictive of speech development in preschoolers with disabilities, clinicians might encourage families to stimulate these productions, through modeling and enthusiastic imitation, as we discussed for prelinguistic infants. In addition, the development of consonant production in early childhood has been shown to be a good predictor of speech outcome (Whitehurst, Fischel, Arnold, & Lonigan, 1992), so working on expanding consonant repertoires in prelinguistic children is also important. Bleile and Miller (1993) and De Thorne et al. (2009) presented suggestions that can help facilitate consonant production in children in the earliest stages of speech production. These contexts are summarized in **Box 6-6**. Even if young children are using augmentative and alternative forms of communication (AAC), vocal communication can still be helpful if the child needs to get others' attention, so enhancing the frequency, volume, and maturity of vocal production may be addressed along with AAC provision.

Hearing Conservation and Aural Habilitation

Older children at prelinguistic levels of development can't tell their parents when they have an earache or if they aren't hearing as well as usual. For these reasons, it is especially important to assess hearing regularly in these populations and to be aggressive, as Roland and Brown (1990) suggested, in identifying and treating otitis media. For children who are found to have impaired hearing, early identification and amplification are two of the most important factors in determining good outcomes. If a hearing impairment is identified in an older prelinguistic child, amplification needs to be introduced immediately. Even a child with hearing impairment (HI) who has significant impairments in cognitive and motor areas can benefit from amplification. If amplification can boost auditory stimulation and increase prespeech vocalization in a prelinguistic client, there will be more vocalization that the clinician can work with and shape into speech-like communication. Parents and teachers also need to learn how to

manage and maintain the child's aids in good working order. In addition, as with any child with HI, the older prelinguistic client may benefit from assistive listening devices, such as auditory trainers, to improve signal-to-noise ratio and maximize the benefit the child can receive from the auditory environment. For children who are good candidates, cochlear implantation can also be considered.

Child Behavior and Development

Older prelinguistic clients may become frustrated over the difficulty of getting their messages across to others. For this reason they sometimes display aberrant or maladaptive behaviors such as aggression or self-abuse. Donnellan, Mirenda, Mesaros, and Fassbender (1984) were among the first to suggest that these behaviors can be understood as a form of communication for clients who do not have more conventional, comprehensible means at their disposal. These behaviors are sometimes inadvertently reinforced by parents and teachers, who pay a great deal of attention to a child who is engaging in them. In these cases, one goal of intervention is to provide clients with more acceptable means of expressing their intentions. If, for example, analysis of a child's maladaptive behavior indicates that it is being used to signal frustration with an intervention activity, the child can be given a conventional means of expressing the same idea. A client might, for example, be taught to use the sign for "stop" to signal that he or she has had enough. When the client uses this signal, it must, of course, be respected to reinforce its communicative value. The teacher or clinician will have to do something else with the client once he or she has asked in this more conventional way to have the activity cease. Bopp, Brown, and Mirenda (2004) and Prizant and Wetherby (2005b) discuss the use of positive behavioral support to achieve this end; more detail on their discussion can be found in Chapter 9.

Another approach to coping with maladaptive communication in older prelinguistic clients is to use what LaVigna (1987) called *differential reinforcement of other behavior (DRO)*. If clients are using maladaptive forms of communication to secure attention from adults, these behaviors can be decreased by systematically paying attention to more acceptable behaviors. In this way the client learns that it is not necessary to be disruptive to gain adults' attention.

BOX 6-6 Suggestions for Facilitating Consonant Production in Early Speech

- To increase length and rhythm of productions, engage the child in simple repetitive motor activities, such as bouncing on a large ball while modeling repetitive syllables in time with his movement (/ba, /ba/, /ba/). Stop periodically to attempt to get him to make the sound in order to continue the activity. When he can produce one syllable fairly consistently, switch to a different single syllable (/mi, /mi/, /mi/), then string repeating syllables together (/baba/, /baba/, /baba/), then nonrepeating syllables (/bama/, /bama/, /bama/). Eventually add words ("go, go, go," "jump, jump, jump").
- To connect sounds to with meaning, teach songs such as "The Wheels on the Bus," with verses that include simple sounds (the wipers on the bus go whoosh, whoosh whoosh; the babies on the bus go wah, wah, wah . . .).
- Encourage expression of emotion with conventional vocalizations. Set up games and routines in which exclamations such as "yeah!" "wow!" "uh-oh!" "haha!" and "wheel!" are used in playful interactions.
- Use stressed syllables to facilitate consonant production (*baby* to facilitate /b/).
- Use velar consonants to facilitate closed syllables.
- Introduce alveolar consonants before a front vowel (*tea* to facilitate /t/).
- To facilitate production of a consonant at a new place of articulation, use a word that contains another consonant at the same place of articulation (*toss* to facilitate /s/).
- Use words with fricatives between vowels (*taffy* to facilitate /f/) to elicit first fricatives.

Adapted from Bleile, K., and Miller, S. (1993). Infants and toddlers. In J. Bernthal (Ed.), *Articulatory and phonological disorders in toddlers with medical needs* (pp. 81-109). New York: Thieme; DeThorne, L. S., Johnson, C. J., Walder, L., and Mahurin-Smith, J. (2009). When "Simon Says" Doesn't Work: Alternatives to Imitation for Facilitating Early Speech Development. *American Journal of Speech-Language Pathology*, 18(2), 133-145.

In addition to maladaptive forms of communication, a second area of concern for the older prelinguistic client's development has to do with the progression of cognitive and communicative skills. For older prelinguistic clients, ongoing assessment is necessary to detect whether a shift from preverbal to verbal communication is taking place or could take place with a "push" from the environment. Evidence presented by Pickett et al. (2009) suggested that children as old as 12 have been known to acquire speech. For prelinguistic clients, even when an AAC system is used, continual probes should be used to investigate whether symbolic skills, including linguistic communication, can be acquired. Ongoing cognitive and play assessment using instruments such as the *Developmental Assessment for Individuals with Severe Disabilities—2nd Edition (DASH-2; Dykes & Erin, 1999)* can help to identify the point at which cognitive skills capable of supporting more symbolic communication—in forms such as speech, sign, print, or Blissymbols—can be added to the client's communicative repertoire. For clients with autism particularly, written language may be a useful augmentative modality for aiding in the acquisition of symbolic language.

Intentionality and Communication

Although clients in the prelinguistic stage may not communicate by conventional means, they do communicate, as Siegel-Causey and Guess (1989) pointed out, but these communications may be difficult to interpret. We need to be prepared to search for and identify any such nonconventional forms, whether they appear in guise of *echolalia* (the echoing of others' speech); aggressive or self-abusive behaviors; touching or manipulating others; bodily orientation; generalized movements; or changes in muscle tone (Siegel-Causey & Guess, 1989). Johnson, Baumgart, Helmstetter, and Curry (1996) suggest looking for a behavior that tends to precede the maladaptive one and attempting to use that as a communicative gesture. For example, if the client protests by hitting, the clinician can interrupt the hitting and prompt the client to simply raise an open hand as an alternative. Some formal assessment procedures for guiding this process have been developed by Coggins, Olswang, and Guthrie (1987); Johnson et al. (1996); Linder (1993); Lund and Duchan (1993); Kleiman (2003); Matson and Minshawi (2007); Norris and Hoffman (1990a); and Wetherby and Prizant (2003). Giving children acceptable, readable means to express the intentions they have, whether the form is spoken or through AAC, is a primary goal of intervention for older prelinguistic clients.

In addition to helping older prelinguistic clients map intentions onto acceptable forms of expression, we may need to expand the frequency and range of intentions they express. Wetherby, Yonclas, and Bryan (1989), for example, showed that children with various types of disorders showed different patterns of communication. Children with DS showed communicative skills that were similar to those of normal children. Children with autism (Mundy & Burnette, 2005) have been shown to demonstrate a normal frequency of communicative acts but an abnormal preponderance of regulatory acts (e.g., requests and protests), unlike normal children, who use predominantly joint attentional acts (e.g., showing, directing attention, showing off). Paul and Shiffer (1991) found that toddlers with slow language development also showed a dearth of joint attentional conversational acts when compared with normally developing toddlers. Mirenda and Santogrossi (1985) discussed the fact that clients with severe intellectual disability often don't

communicate much at all without prompting, even when they have communicative means available. These studies suggest that differences in the frequency and range of communicative function need to be addressed in older clients at the prelinguistic stage. Such clients may need to develop a broader base of preverbal intentions at the same time that conventional communication, in speech or AAC, is being acquired. Several commercially available programs can address this issue, including the Ski-Hi curriculum developed for children with hearing impairment (Clark & Watkins, 1985), the INSITE program (Clark, Morgan, & Wilson-Vlotman, 1984), and the ECO Model (MacDonald, 1989). Ronski and Sevcik's (1996) System for Augmenting Language (SAL) also is a useful model. Communication temptations are another way to help elicit communicative functions that a child is not showing spontaneously.

Mirenda and Santogrossi (1985) suggest using a "prompt-free" approach as a way to elicit beginning intentional communication. The client can be rewarded with a piece of cereal each time he or she accidentally touches a picture of the cereal box that has been set in his or her view, for example. As these touches become more frequent and intentional, the ante can be "upped" by requiring that the child not only touch the picture but look at the adult to accomplish a request. More pictures can then be added, until a communication board or a book with a variety of pictures and symbols can be used by the client to get messages across. In this way the frequency of communication can be expanded as a functional AAC system is introduced. Communication temptation activities adapted to the client's physical abilities also can be an important part of this process.

Yoder and colleagues have done several studies (e.g., Yoder & Stone, 2006; Yoder & Warren, 2001) to demonstrate the efficacy of Milieu Communication Training (MCT), which we discussed in Chapter 3. They have shown it is particularly effective for helping children with disabilities make the transition from preintentional to communicative behavior. The major characteristics of MCT include:

- Training is undertaken in everyday environments (e.g., home or classroom) rather than a "therapy room."
- Activities take place throughout the day, rather than only at "therapy time."
- Preferred toys and activities are included in the environment so that participation in activities is self-reinforcing.
- Adults encourage spontaneous communication by refraining from prompting and using "expectant waiting" (use of gaze, posture, and facial expression to indicate the adult expects the child to do something).
- The child initiates teaching situation by gesturing or indicating interest in a desired object or activity.
- Teachers provide prompts and cues for expansion of the child's initiation.
- Expanded child responses are rewarded with access to a desired object or activity.

AAC approaches are often appropriate for students at the prelinguistic stage. These may include books with a small set of simple pictures or photographs that the client can easily transport and point to in order to request objects or activities. Electronic devices such as iPhones and iPads also have applications that can be adapted to display pictures a child can point to. Some of these applications serve as voice output devices that will speak the word for a picture the child touches. These devices are less stigmatizing than a picture book, and they may aid in providing avenues for social interaction, since typical children will find them both familiar and

attractive, and may even want to use them to “talk” with the client. Simple switch devices, those specifically designed for AAC, or consumer products like talking picture frames can be programmed to speak a small number of words or phrases to allow a client to make simple requests. Sources such as Binger and Kent-Walsh (2009), McNaughton and Beukelman (2010), and Mirenda and Beukelman (2006) are available as references for work with clients who require AAC.

Part of the difficulty for prelinguistic communicators is not only that they don’t talk; they also don’t have the underlying linguistic knowledge to make connections readily between words and their referents or to acquire grammatical structures. Developing AAC for these clients requires identifying a relatively small number of ideas the child will be taught in order to maximize communicative potential. Cannon and Edmond (2009) call this small set of functional, high frequency words that can be used across a range of situations a “core vocabulary.” Choosing what to include in this core set of words/symbols to teach can be a challenge, but they advise being sure to teach not only nouns, but functional verbs such as *want*, *give*, *go*, *help*, and *come*, and other important words such as *more*, *good*, *bad*, *yes*, *no*, *mine*, and *wow*, as well as words from a set of functional categories such as foods, toys, self-help items, and favored activities. Choosing pictures, symbols or written forms the child can learn to identify for each concept, placing them in easy-to-transport containers (either paper or electronic), and providing arrays that are easy to locate are all part of the job of designing effective AAC systems for prelinguistic communicators. In addition to the resources cited above, many Web-based resources are available to provide help with AAC issues. Just a few examples include:

www.asha.org/public/speech/disorders/AAC.htm
<http://trace.wisc.edu/>

<http://aac.unl.edu/>
www.isaac-online.org

Halle, Brady, and Drasgow (2004) and Keen (2003) discussed the fact that the prelinguistic communications of children with severe disabilities are often misunderstood, so that frequent communication breakdowns occur. Halle et al. suggested guidelines for programs to help clients repair these breakdowns. These appear in Box 6-7. Attention to repairing communicative breakdowns can help to decrease frustration and provide more effective communication for these individuals. Kevan (2003) reminds us also that communication difficulties may arise not only from expressive limitations, but also from inability to comprehend language spoken to these clients. She emphasizes the importance of careful and thorough assessment of receptive language as part of the evaluation of these students.

A final consideration in organizing a communication system for children with severe impairments involves helping to create more transactional support in their environment and their communication partners for their communicative attempts. Several methods are available for assessing the interactive environment in order to determine how to make it more congenial for the client’s communication. McCarthy et al.’s (1998) *Communication Support Checklist* and Rowland and Schweigert’s (1993) *Analyzing the Communicative Environment*, the *Functional Communication Profile—Revised* (Kleiman, 2003), and the *SCERTS Assessment Process* (Prizant et al., 2006) are instruments to assist in doing these evaluations. It is vital to learn how the communicative environment responds to prelinguistic clients because nonspeaking children (even those with typical cognition) use less communication than would be expected for their developmental level (Falkman, Sandberg, and Hjelmquist, 2002) primarily because environmental supports for communication via AAC are lacking. When developing AAC

BOX 6-7 Guidelines for Teaching Repair of Prelinguistic Communication Breakdowns

- Identify (1) situations in which communication breakdowns are occurring or are likely to occur, (2) function of the communicative behavior associated with the breakdowns, and (3) the responses of social partners in those situations.
- Select AT LEAST two new forms to teach as repairs. Focus intervention on teaching replacement forms that produce a good contextual fit with the demands of the situation.
- Select forms that have wide application and are more efficient than existing repairs. For example, if a child is at the one-word stage, a socially appropriate alternative response might be to point to the desired object. Be sure the new behavior has immediate, consistent, and positive responses from the communication partner.
- Teach the new forms by creating situations that replicate the natural situations in which breakdowns are likely to occur. Have team members agree upon a prompting system, such as graduated guidance or verbal prompts that they can use to ensure that the child will use the new forms. Use a milieu teaching approach, in which adults observe the child carefully and then insert teaching trials at motivating moments. Help the child learn to use an alternate repair strategy if the first fails. This can be accomplished by responding quickly to most opportunities when the child uses a new repair form and, on some small number of occasions, waiting and prompting a second new repair form when the child has already attempted repair. Be sure social partners do not respond to any existing socially unacceptable communication. When it is not possible to ignore unacceptable communication, attempt to ensure that the consequence is less immediate, less consistent, and of lesser quality than consequences for socially appropriate communication.
- Encourage social partners to be responsive to the new forms. Select communication forms that are easily recognized and understood by a variety of social partners. Model the forms for the social partners and alert them to the situations in which the new forms are most likely to occur. Encourage social partners to respond more quickly, more often, and with greater magnitude to the new repair forms.
- Monitor use of new repair forms. Look for instances of new repairs in the child’s everyday settings under communicative breakdown situations. This information can be used to guide and refine instructional strategies because it provides ongoing assessment information about the progress of the interventions.

Adapted from Halle, J., Brady, N., & Drasgow, E. (2004). Enhancing socially adaptive communicative repairs of beginning communicators with disabilities, *American Journal of Speech-Language Pathology*, 13, 43-54.

systems, then, it will be crucial to work with parents, teachers, and other caregivers to be sure they are responsive to the use of these systems in real communicative situations. Duchan (1997) developed a model for optimizing functional communication in natural settings by preparing both the environment and communication partners to ensure successful inclusion of the client and by programming various kinds of ongoing support. These supports are outlined in Box 6-8.

AUTISM SPECTRUM DISORDERS (ASD)

Children with ASD show a wide range of communication abilities, but almost all are delayed in the acquisition of spoken language (Paul et al., 2007), and show a restricted range of prelinguistic communicative intentions (e.g., Clifford & Dissanayake, 2008; Watt et al., 2006; Wetherby et al., 2007). So many children with ASD will present as prelinguistic communicators throughout the preschool period, and 20% to 40% will continue as such into school age. Many of the approaches we have discussed for other prelinguistic communicators, aimed at eliciting first communicative intentions and expanding the range of intentions expressed are appropriate for children with ASD, as well. Methods that have an evidence base specifically for the ASD population include AAC

and MCT (Prelock et al., 2011). In addition to methods we have discussed for other diagnoses, one additional approach is particularly relevant for children with ASD: the discrete trial and behaviorist techniques we discussed under the heading of clinician-directed intervention in Chapter 3. These methods are usually referred to under the general umbrella of applied behavior analysis (ABA). ABA is the broad term used to describe a range of procedures developed by psychologists from a behaviorist or operant school of thought. The methods of this approach include:

- *functional analysis*: This involves objective assessment of the antecedents and consequences of behaviors to be elicited or eliminated. Behavioral theory assumes that behaviors are triggered by environmental events; its goal is to engineer the environment so that desirable behaviors are evoked and undesirable behaviors are extinguished. To do this, antecedents for undesirable behaviors must be identified, so that they can be removed from the child's experience and do not trigger the maladaptive behavior. Similarly, consequences that increase the frequency of desirable behaviors must be identified, so these can be provided to evoke new adaptive behaviors.
- *task analysis*: Goals targeted by functional analysis are broken down into their most fundamental steps. The first step is trained intensively until the child can produce it in response to the appropriate environmental stimulus with minimal

BOX 6-8 Providing Transactional Support to Enhance Communication

SUPPORT	EXPLANATION	EXAMPLE STRATEGIES
Social Support	Helping each communication partner to understand and expand on their assigned roles	• Adjusting the complexity of input, using simpler language • Modeling use of communicative device in <i>input to client</i> as well as by client
Emotional Support	Helping partners to respond to the emotional state of one another	• Providing and responding to client requests to "stop," "start over," etc. • Adjusting task difficulty if client becomes frustrated • Choosing motivating, chronologically age-appropriate materials
Functional Support	Helping partners to achieve their communication goals and to understand and support their partner's goals	• Creating clear opportunities for client to fill in a turn in a back-and-forth activity • Providing a predictable sequence of activities • Arranging the environment to minimize distraction and enhance attention • Providing a clear beginning and end to each interchange
Physical Support	Providing access to communication and physical support for enhancing communication	• Using visual supports to provide a predictable, organized sequence, enhance attention, and encourage involvement in group activities • Using AAC devices and methods • Using prompts and cues to encourage participation
Event Support	Scaffolding events to provide contextual support for communication, to establish participation patterns, and to let participants know what to expect	• Providing activities that include movement as well as sitting • Providing visual schedules to enhance predictability and ease transitions • Offering repeated opportunities to practice new skills with different partners • Coaching within natural interactions to remind client of skills taught
Discourse Support	Providing scaffolds, discourse markers, and discourse support to expand on and encourage communication of others	• Providing opportunities and scaffolds to initiate interactions • Using coaching and modeling to extend interactions

Adapted from Duchan, J. (1997). A situated pragmatics approach for supporting children with severe communication disorders. *Topics in Language Disorders*, 17 (2), 14; Prizant, B. and Wetherby, A. (2005). Enhancing communication abilities for persons with autism spectrum disorders. In F. Volkmar, R. Paul, A. Klin, and D. Cohen (Eds.) *Handbook of Autism and Pervasive Developmental Disorders*. (pp. 925-945). N.Y.: Wiley.

prompting. The next step in the sequence is then “chained” to the first, so that the child must now produce both steps in the sequence to obtain reinforcement. “Backward chaining” is sometimes used in which the child is initially required only to produce the last step in a sequence, then earlier steps are systematically chained to the last, until the child can produce the entire sequence.

- *selection and systematic implementation of effective reinforcers:* Children with ASD often find unusual objects and activities rewarding. ABA approaches identify what serves as a reward for each individual, and then use these rewards according to systematically determined schedules in order to manage maladaptive behaviors and elicit more adaptive ones. Correct responses and behaviors are rewarded with positive reinforcement; incorrect responses and undesirable behaviors are disregarded to as great a degree as possible.

These methods can be incorporated into highly structured activities such as discrete trial training (see Chapter 3) using edible or other tangible reinforcement, or into somewhat more loosely structured activities, such as drill-play (see Chapter 3) that include social or natural reinforcers. It is important to understand that ABA methods are not limited to discrete trials. Activities that we would call hybrid, such as MCT or Picture Exchange Communication System (PECS), can be included under the ABA umbrella. A range of ABA methods, including discrete trials, have been shown to be effective in increasing communicative and other adaptive behavior for children with ASD (see Rogers, 2006; Paul, 2008a; Prelock et al., 2011; Reichow & Wolery, 2009; Smith, 2001 for review), most likely because these children benefit from the highly structured, routine, predictable organization of ABA procedures. Smith (2001) advised that these methods be part of any program for children with ASD, although other methods should also be included. Several ABA programs have been specifically designed to teach language to children on the autism spectrum. These include *Teach Me Language* (Freeman & Dake, 1997), *Verbal Behavior* (Partington & Sundberg, 1998), and *The Me Book* (Lovaas et al., 1980).

An additional method developed specifically for prelinguistic children with ASD was Bondy and Frost’s (2002) PECS. Its primary aim is teaching functional communication initiations. Its goal is to avoid prompts or directives, but to get the client to communicate spontaneously. The client is presented with a desired object (e.g., a cookie) and its picture. When the client reaches for the cookie, an aide standing behind him directs his hand to the picture and guides him to give it to the clinician. When she receives the picture, she exchanges it for the cookie. This procedure is continued, through backward chaining (Sulzer-Azaroff & Mayer, 1991), until the client hands the picture to the clinician spontaneously. The program then focuses on enhancing spontaneity, discriminating among symbols, and acquiring other functions of communication beyond requesting. Several meta-analyses (Flippin, Reszka, & Watson, 2010; Banda, McAfee, & Hart, 2009; Kai-Chen, 2008; Prelock et al., 2011) have established that PECS instruction improves communication, although not necessarily speech.

Yoder and McDuffie (2006) emphasized that many prelinguistic children with ASD will need to develop the foundations for communication before they acquire spoken language. They argued that these foundations include symbolic play and nonverbal communication accomplished through gestures and vocalizations coordinated with gaze. Rogers, Cook, & Meryl (2005) argue that an additional foundation skill is gestural and vocal imitation, which is also significantly impaired in ASD. Koegel and Koegel (2006) call

all these *pivotal* skills, because acquiring them tends to increase children’s responsiveness to treatment. The pivotal skills of symbolic play, nonverbal communication, and imitation have been shown to increase response to language treatment specifically. But Yoder and McDuffie argue that it is not necessary to wait for a child to acquire these pivotal skills before starting treatment to elicit speech. They advocate working on both pivotal and language skills simultaneously. Paul (2009) suggested that intervention for preverbal preschoolers with ASD should include short, daily sessions of discrete trial intervention aimed at motor, vocal, and eventually verbal imitation, while the remainder of intervention time should be focused on hybrid and child-centered activities to enhance pivotal skills, and should include parent training, using methods such as *More Than Words* (Sussman, 1999), Ingersoll, & Dvortcsak’s (2010) Social Communication training program for parents, or *Parent Responsiveness Training* (Yoder & Warren, 2002) to help parents enhance their children’s communication in everyday activities and routines.

The provision of AAC for nonspeaking children with ASD, using methods such as PECS or voice-output communication devices, has also been studied in this population. Like AAC for other communication disorders, this approach has been shown not to preclude the development of speech, although it is not associated with dramatic increases in speech, either (Nunes, 2008; Schlosser & Wendt, 2008). Toth (2009) suggested that AAC may serve as a temporary bridge to speech for some children with ASD. As such, work with AAC may also take place during the same time period that pivotal skills and specific speech treatment is being provided. Since the National Research Council (2001) has recommended that preschool children with ASD receive 15 to 30 hours per week of focused intervention, there should be time for the inclusion of all these elements—as well as work on peer interactions, pre-academic skills, motor abilities, self-help skills, and replacement of maladaptive behavior—in comprehensive programs for these young children.

The role of the SLP, however, will be primarily to establish pivotal skills for language acquisition (i.e., symbolic play, nonverbal communication, and imitation), to work toward the acquisition and generalization of speech as a mode of communication, to provide AAC as a transitional approach for those children who need it, and to train parents and other educators to enhance social communication opportunities and responsiveness throughout the child’s day. The methods for teaching all these skills can include a range of approaches such as discrete trials; naturalistic, hybrid ABA approaches such as MCT; as well as facilitative play and coaching of social interactions with typical peers. It is also important to be aware that many children with ASD have feeding difficulties. Twachtman-Reilly, Amaral, & Zebrowski (2008) provide guidance in addressing these issues in school settings.

There will be some children with ASD, as there are children with intellectual disability, who do not acquire spoken language during their preschool years. Although the proportion of these children has decreased—and there are numerous examples of school-aged children with ASD who have acquired spoken language for the first time, usually through the application of discrete trial procedures (Pickett et al., 2009)—in general, nonspeaking children over the age of 6 require a long-term AAC system that will provide as effective a means of communication as possible. SLPs will be primarily responsible for establishing AAC for these individuals. The system that will work best for a particular child will have to be discovered by experimentation. Options include Signs, pictures, Bliss Symbols, as well as written language. Some

children with ASD show special affinity for alphabet letters and can be taught to read even when other abilities would not suggest readiness for reading. Aided systems such as voice output communication aides (VOCAs) that use either pictures or written words as input have been used successfully with this population, and should be considered when developing an AAC system for nonspeaking older children with ASD, using normative platforms such as smart phones and notepad computers whenever possible to decrease stigma. Cafiero (2005) and Miranda (2008) provide resources on the use of AAC for children with ASD.

CONCLUSIONS

Although infants and other children at prelinguistic levels of communication may look like two very different groups of clients, our goals for these two categories are in some ways very similar: helping caregivers learn to read and respond to the child's signals and supporting the family in providing an enhanced communicative environment for the child, improving feeding and vocal skills, conserving and making best use of hearing, and developing functional communication that has the potential to grow into symbolic language. The SLP has two unique goals in working with at-risk infants and their families: primary and secondary prevention of communication disorders in the infant. The vehicle by which we accomplish these goals in the first years of life is the IFSP. Remember Janice? [Box 6-9](#) gives an example of an IFSP that might have been developed for her and her family. An additional IFSP sample format appears in [Appendix 6-2](#).

The IFSP in [Box 6-9](#) exemplifies several of the critical elements we discussed with regard to work with high-risk infants and their families. First, it looks at the baby in the context of the family. Notice that the intervention services outlined in the plan are exactly the ones that the family identified as their priorities and concerns in their discussion with the IFSP team. Second, the goal of the IFSP is not concerned with prediction of the baby's ultimate outcome but provision of what the baby needs now to achieve maximal potential. Goals are not chronologically age-appropriate milestones, but simply those behaviors that Janice's family feels are important for her to develop now. Finally, the IFSP integrates services from a variety of providers under the watchful eye of a case manager, who develops a real relationship with the family and advocates for them and their concerns.

The SLP has a unique opportunity when working with the family of an at-risk infant. Very often in our profession we are trying to fix what is already broken. With a baby who starts out with risk factors, though, we may have the chance to prevent things from getting broken in the first place. This is a rare opportunity and one that we ought, as a profession, to embrace. Despite our best efforts at primary and secondary prevention, many of the babies we work with will develop communicative problems that we will need to address with rehabilitative methods. However, for some infants, we may be able to ward off the effects of early difficulties. A detailed and comprehensive understanding of infant development and communication, as well as knowledge of the techniques to enhance that development, will ensure that we can take advantage of this invaluable opportunity.

We have some special opportunities when we work with older prelinguistic clients as well. These children may have spent a good part of their lives in enforced isolation because of their inability to find ways to express their interests and desires. Developing a conventional communication system for a child who has never had

one can make a tremendous difference in the quality of that child's life. Giving the gift of communication to such a child is also an achievement in which we can take a good deal of pride.

STUDY GUIDE

- I. Family-Centered Practice
 - A. What is IDEA?
 - B. Describe the Individual Family Service Plan. Name its required elements. How is it used to provide family-centered services to handicapped infants?
 - C. Discuss the uses and dangers of family assessment.
 - D. Discuss communication strategies that can be used in family-centered practice.
 - E. Why is a speech-language pathologist needed on the team that plans services for the at-risk infant?
- II. Risk Factors for Communication Disorders in Infants
 - A. Discuss some of the prenatal factors that can place a child at risk for developmental and communicative disorders.
 - B. How does prematurity influence communicative development?
 - C. Name and describe six genetic conditions that place an infant at risk for communication disorders.
- III. Assessment and Intervention for High-Risk Infants and Their Families in the Newborn Intensive Care Nursery
 - A. Discuss the formal and informal methods available for assessing feeding and oral-motor development in infants.
 - B. Discuss the pros and cons of three major types of nonoral feeding used in the NICU.
 - C. Describe three ways the SLP can facilitate oral feeding in at-risk newborns. What instruments can be used to assess feeding skills?
 - D. How and why should the SLP promote hearing conservation in the NICU?
 - E. What is the purpose of assessment of infant behavior and development?
 - F. What information can the SLP gather in the NICU to assess infant development? What are some of the ways the SLP can contribute to the infant's development in the NICU?
 - G. When is a newborn ready to take advantage of interaction? Discuss the signs of readiness. How can we help families recognize them?
- IV. Assessment and Intervention for Preintentional Infants and Their Families: 1 to 8 Months
 - A. Discuss methods for improving feeding skills in a 6-month-old baby.
 - B. Describe how you would use the assessment of vocal behavior to evaluate an 8-month-old baby. What could be done to enhance vocal production during the first year of life for a baby showing poor vocal skills?
 - C. List several instruments that can be used to assess infant development. What instruments are available for assessing early communicative development?
 - D. How can the SLP work to coordinate services for infants and their families?
 - E. How can assessment of parent-child communication be made family-centered?
 - F. Discuss the three areas in which the SLP can work to enhance parent-infant communication.

BOX 6-9 Example of an IFSP for Janice

Name: Janice XXX
Date of Birth: May 22, 2011
Chronological age: 7 ½ weeks, uncorrected
Sex: Female
SSN: 000-00-000
Case Manager: Kay Jones, CCC-SLP
Assessment date: July 14, 2011
Legal Guardian: Mary and Henry XXX
Siblings: Jenna, 2.6, Harry, 4.8
Address: 6500 S. 36th Ave.
Phone: (205) 555-3788
Referred by: University Hospital

HISTORY

This is the first follow-up assessment for Janice after she left the NICU. She was the product of an otherwise uneventful pregnancy and was identified as having DS at birth. She was born at 32 weeks, weighing 3 lb. 2 oz. Ventilator treatment was needed for respiratory distress syndrome. She was intubated and received gavage tube feeding for the first 2 weeks in the NICU, then graduated to bottle feeding. Initially, feeding was difficult, but her mother was very determined to make the bottle feeding succeed, which it soon did. Janice was removed from the incubator after 3 weeks and did well in the NICU until discharge, at which point she weighed 5 lb. 3 oz.

CURRENT STATUS

The *Brazelton Neonatal Behavioral Assessment Scale* was administered to Janice just before discharge from the NICU. Janice's performance on three of the Brazelton scales—motor capacities, organizational capacities (state), and organizational capacities (stress)—was considered within normal limits. Her score on the interactive capacities scale, however, indicated reduced ability to attend to and process environmental events and to respond to faces and voices.

Hearing status was found to be normal on auditory brainstem-evoked response testing. Vision screening could not be accomplished and should be performed at the next assessment. Hearing status should be monitored regularly because of risks associated with DS.

FAMILY RESOURCES, PRIORITIES, AND CONCERNS

Extensive discussion with Janice's mother and some less extensive conversations with her father revealed the following:

Resources

Janice's mother says she is determined to do the best she can for this baby, even if she has to give up her job; she will stay home with Janice as long as she feels Janice needs it. The mother reports that she was frightened about Janice's retardation, but now that she's seen how far Janice has come in the last few weeks, she feels confident that she can help Janice to achieve her potential.

Priorities

Janice's mother has been expressing breast milk throughout her stay in the NICU and would like very much to breastfeed Janice now that she is home. She is willing to do so even on a supplementary basis and to continue bottle feeding to maintain weight gains. The mother also is very interested in having Janice interact with her brother and sister, so that they can "get to know the baby." Janice's father wants life at home to return to some semblance of normal and hopes now that Janice is home he will see more of his wife and have things run more smoothly. He would like to give Janice's mother some help at home but cannot afford to hire help.

Concerns

Janice's mother is worried about her job and wonders whether she will be able to keep it and still give Janice what she needs. She and her husband are both concerned about the financial repercussions of Janice's hospitalization. They are concerned about their ability to care for a child with intellectual disability over the long term. Their main concern now is to be sure that Janice get everything she needs to grow and develop, but they also are worried that their children will feel slighted or abandoned because of all the flurry around Janice.

OUTCOMES

1. Encourage breastfeeding. SLP will work with mother on positioning to maximize baby's intake during breastfeeding. *Criteria/timeline:* Mother will report on success of breastfeeding at next IFSP meeting; weight gain will be monitored by a pediatrician.
2. Effect of vision on Janice's difficulty in attending to faces will be evaluated. *Criteria/timeline:* Vision check at next pediatrician visit.
3. Provide emotional and financial support to family. Social work service will explore supplementary insurance issues as well as visiting nurse and home health aide services for Janice. *Criteria/timeline:* Check with family at next IFSP meeting; home health aide should be provided within the next month, if at all possible.
4. Provide home visits to develop Janice's interactive skills, particularly with siblings. SLP will meet with both parents to discuss interactive activities and will focus particularly on ways that the siblings can play with the baby. *Criteria/timeline:* SLP will meet monthly with the family to teach and monitor interactive activities. Janice's communicative development will be evaluated formally at 6 months to decide what further intervention is needed at that time.

Continued

BOX 6-9 Example of an IFSP for Janice—cont'd**EARLY INTERVENTION SERVICES AND DATES OF INITIATION OF SERVICES**

1. Monthly meetings with SLP to develop breastfeeding and interactive activities. Begin July 21, 2011.
2. Social work services to explore financial and other assistance. Meet with social worker before the end of July 2011.
3. Visiting nurse or home health care to provide help to the mother as soon as can be arranged by social work service.
4. Explore possibility of classroom-based program for Janice with Regional Early Intervention Collaborative when Janice reaches eligibility age for program (12 to 18 months).

Case Manager

SLP Kay Jones will coordinate services, do monthly home visits with family, contact social work services, and arrange next IFSP meeting after Janice's 6-month development assessment by the pediatrician.

TRANSITION TO PRESCHOOL SERVICES AT AGE 3

SLP will coordinate multidisciplinary development evaluation at 30 months and arrange for coordination and transfer of information to school system Child Find team and oversee their evaluation and recommendations for preschool services. Case manager will argue for need for early intervention services in light of Janice's DS diagnosis.

- G. Name four interactive behaviors the SLP can encourage parents to use with their babies.
- H. To what cultural issues must the SLP be sensitive in teaching baby games to parents?
- V. Assessment and Intervention for Infants at Prelinguistic Stages of Communication: 9 to 18 Months
 - A. How do the infant's communicative needs change in the last quarter of the first year of life?
 - B. How can play assessment be used to evaluate the cognitive level in the prelinguistic infant?
 - C. Discuss the term *upping the ante*. How does it apply to intervention for the prelinguistic infant?
 - D. How and when should communication temptations be used?
 - E. How is language comprehension fostered in the prelinguistic infant?
 - F. What parent training programs are available for the SLP to use in fostering parent-infant communication?
- VI. Considerations for Older Prelinguistic Clients and Those with ASD
 - A. Describe techniques that can be helpful in developing feeding skills in prelinguistic clients.
 - B. How do communication issues relate to feeding? Give examples of some strategies to deal with these issues.
 - C. How are the development of feeding and speech related?
 - D. Describe five methods used to assess feeding skills in infants or older prelinguistic clients.
 - E. How can maladaptive forms of communication be addressed?
 - F. How can we find out whether a client is ready to move from illocutionary to locutionary communication?
 - G. Describe the PECS and talk about clients for whom it might be appropriate.
 - H. Discuss methods of helping clients with prelinguistic communication repair communicative breakdowns.
 - I. Discuss several approaches to communication intervention that are appropriate specifically for prelinguistic children with ASD.
 - J. What are pivotal skills for communication development in prelinguistic children with ASD?

Developing Family-Centered Clinical Practice

Situation	Guidelines for Practice	Intended Outcomes	Communications Strategies
First encounter with family	1. Allow and encourage family members to describe interests before describing services. 2. Provide choices and allow family to make decisions. 3. Avoid being too nosy. 4. Let family know what information you have received from other professional and ask whether they feel it is accurate and unbiased. 5. Reaffirm confidentiality. 6. Respond quickly and don't push families off until "later."	1. To convey to families that you respect them 2. To offer immediate assistance if it is wanted (information, resources, emotional support, services, skills) 3. To give family members control over entry into services (decision making, choices) 4. To let family members know who you are and what you do (e.g., philosophy, qualifications, services) 5. To understand the family's major areas of concern and priorities	1. How are things going with (client)?
Gathering client and family data	1. Requires continuous opportunities for gathering exchanging, and interpreting information. 2. Families should have the opportunity to be present for all discussion. 3. It should be convenient for the family to participate. 4. The language used in communicating with families should be readily understood (e.g., jargon-free, using the family's own words).	1. To identify what families hope to achieve through involvement with you and your agency 2. To determine how families define the issues related to the client's handicapping condition within the context of their family values, structures, and daily routines 3. To establish yourself as a family ally	1. What have you been told about (client's name) (hearing, vision, motor skills, etc., using words of family members)? 2. How does this fit with what you know and believe about (client's name)? 3. What else do you know about (client's identified disability)? 4. In what ways has this information been helpful? Or not helpful?
Involving family in assessment process	1. Assessment should be shaped by family priorities and information needs. 2. Assessment should meet the needs of the family rather than the needs of the program or staff. 3. Preferences for family involvement should be identified and honored.	1. To request and use information provided by family members to understand the client's abilities and plan intervention 2. To promote the building of consensus about the nature of the presenting client and family needs 3. To underscore the client's and family's abilities and potential	1. For what areas do you need or want more information concerning (client's name)? 2. What kinds of information would be most useful to you regarding (client)? 3. Where and what would be the best place and time to assess (client)? 4. Are there other people who you might like to be involved in the assessment? 5. How have you been involved in assessment activities previously? 6. Was that type and level of participation satisfactory to you? 7. Are there additional ways you would like to be involved? 8. If so, which activities would you like to be a part of (e.g., stay with client, sit outside and observe, fill out checklist or survey, perform actual testing)?

Continued

Situation	Guidelines for Practice	Intended Outcomes	Communications Strategies
Reporting assessment information to family	1. Assessment information should be shared at a time and place that are suitable for family members. 2. Families should decide who will be present and how the information will be shared. 3. Families should decide what type of assessment information will be helpful to them. 4. Families should determine when intervention planning will take place.	1. To promote the building of consensus on the nature of the needs of the client and family and the need for treatment 2. To provide family members with information about the client so that they may be able to make informed decisions regarding further assessment and intervention 3. To promote and support family decision making regarding further assessment and/or intervention 4. To promote the building of consensus on the course of action that follows`	1. Where and when would you like the assessment information shared? 2. Who would you like to be present when the information is shared? 3. What part in the information sharing would you like to take? 4. How would you like the information to be shared (e.g., face to face, in writing, in detail, just in an overview, citing age levels)? 5. If face-to-face interaction, whom would you like to go first in presenting information? 6. Are there particular topics you would like discussed first? 7. What would you like to take place after the information sharing (e.g., talk about future plans, wait and talk later, follow-up call)? 8. How did you feel about the assessment activities performed with (client)? 9. Do you think that what we saw today was typical of (client)? If not, what kinds of differences did you observe and how are things typically? 10. Were there any areas that we did not assess that you feel would be helpful to assess? 11. What did you think overall of (client's) interactions with the assessors? 12. Were there things that happened today that surprised you? If so, what? 13. How do you feel about the assessment results? 14. What would you like the next step to be?
Planning intervention program with the family	1. Parents should have the opportunity to be involved in all planning meetings related to the client and family. 2. Intervention plans should be designed to fit within the family's daily routine. 3. Families should be the ultimate decision makers regarding intervention planning; individualize practices to match parent needs and preferences. 4. The written plan should be easy for families to understand and use, and flexible enough to allow ongoing changes.	1. To identify priorities and to promote solution development with families related to their priorities 2. To support family decisions	1. If you were to focus you energies on one thing for (client's name), what would it be? 2. If you could change one thing about (event of importance), what would that be? 3. Imagining 6 months down the road, what would you like to be different in terms of (event or area of importance)? Are there some things that you would like to be the same? 4. What would you like to accomplish in 6 weeks? 6 months? 5. What are some ways of getting to where you want to go? Who would need to be involved in accomplishing what you want to do? 6. What would each of you need to do to accomplish what you want? 7. How will you know when you've done what you want to do? 8. How will you know when (client's name) has made progress in the ways you described? 9. How long do you think it will take to get to where you want to go?

Situation	Guidelines for Practice	Intended Outcomes	Communications Strategies
Throughout all contacts	1. Support, trust, and respect parents. 2. Use a strengths-based approach. 3. Understand and accept parent's perceptions and experiences. 4. Coordinate professional team.	1. To maximize receptiveness and effective bonds 2. To support parent's perceptions of child 3. To overcome past negative experiences and form partnerships with professionals 4. To avoid confusing or overwhelming families

Tools for Assessing Infant Development

Scale	Areas Assessed	Comment
<i>Ages and Stages Questionnaires: A Parent-Completed Child—Monitoring System—Third Edition</i> (ASQ-3; Bricker & Squires, 2009)	4–60 mo; Developmental questionnaires sent to parents of at-risk children. Areas screened include gross and fine motor control, communication, personal-social, and problem solving.	Involves parents in the assessment process. Questions available in Spanish, French, and Korean.
<i>Albert Einstein Scales</i> (Escalona & Corman, 1966)	Tactile exploration activities not readily available in other scales.	Provides a qualitative assessment of behaviors.
<i>Assessing Linguistic Behavior</i> (ALB; Olswang, Stoel-Gammon, Coggins, & Carpenter, 1987)	Birth–2 yr; observational scales to assess the performance of cognitive antecedents, play, communicative intention, language production and comprehension.	Provides a developmental level comparison and detailed instructions for administering assessments.
<i>Assessment in Infancy: Ordinal Scales of Infant Psychological Development</i> (Uzgiris & Hunt, 1989)	Follows Piagetian sequences to measure infant development in communicative and social domains.	Used during the sensorimotor period of development; helpful in the development of functional, generative, instructional objectives; useful as a tool to explain the child's level of achievement across developmental domains to parents.
<i>Assessment, Evaluation, and Programming System for Infants and Children—Second Edition</i> (AEPS; Bricker, 2002)	Birth–6 yr; assessment and evaluation of fine and gross motor movements and adaptive, cognitive, and social communication.	Criterion-referenced assessment and evaluation; also includes a family report measure for parents to assess their child.
<i>Battelle Developmental Inventory—Second Edition</i> (BDI-2; Newborg, Stock, Wnek, Guidubaldi, & Svinicki, 2004)	Birth–7:11; cognitive, perceptual, discrimination, memory, reasoning, academic, conceptual behaviors; personal-social, motor, communication, and adaptive.	Specific adaptations for specific handicapping conditions; very comprehensive standardization data for normally developing children; provisions for testing directly, by observation, and by interview; sparse number of items provided for each age range; a good screening tool.
<i>Bayley Scales of Infant Development—Third Edition</i> (Bayley-III; Bayley, 2005)	12–42 mo; sensorimotor skills; cognitive, psychomotor, social, visual, and auditory. Motor scale can be administered separately.	Used with handicapped infants and children; excellent standardization properties; measures a large number of behaviors; some items may be scored based on observations, omissions, refusals, and caregiver reports; not appropriate for children with moderate to severe sensory and motor deficits; most appropriate with children who exhibit mild cognitive delays or mild sensory communication impairments.
<i>Birth to Three Checklist of Language and Learning Behaviors</i> (BTC-3; Ammer, 1999)	A criterion-referenced tool that measures five categories of early skill acquisition, including language comprehension, language expression, avenues to learning, and social behaviors.	Results yield IFSP for the family and child.
<i>The Brigance Infant and Toddler Screen</i> (Brigance & Glascoe, 2002)	Birth–23 mo; fine motor, receptive language, expressive language, gross motor, self-help, and social-emotional.	Parent-report and direct elicitation versions. Spanish direction booklets available.
<i>Carolina Curriculum for Infants and Toddlers with Special Needs—Third Edition</i> (Johnson-Martin, Attermeier, & Hacker, 2004)	Birth–36 mo; cognition, language, self-help, fine motor, gross motor; includes daily routine integration strategies.	Criterion-referenced procedure for developing intervention targets.
<i>Casati-Lezine Scales</i> (Casati & Lezine, 1968)	Searching for hidden objects; use of intermediaries, exploration of objects, and the combination of objects.	Offers additional Piagetian items not included on the Dunst scales.

Continued

Scale	Areas Assessed	Comment
<i>Denver Developmental Screening Test—II</i> (DDST-II; Frankenburg et al., 1990)	Birth–6 yr; assesses four developmental areas: personal-social development, fine motor–adaptive development, language development, gross motor development.	Determines whether a child performs within normal range on various tasks in the areas of personal-social, fine motor–adaptive, language, and gross motor skills; identifies whether a child is likely to have delays in any of those areas.
<i>Developmental Assessment of Young Children</i> (DAYC; Voress & Maddox, 1999)	Birth–5 yr; communication, cognition, social-emotional development, physical development, adaptive behavior.	Normed on 1269 children. One subtest for each of the five domains listed at left. Administration time: 10-20 min. for all 5 subtests Determines developmental functioning age.
<i>Developmental Assessment for Students with Severe Disabilities—Second Edition</i> (DASH-2; Dykes & Erin, 1999)	For individuals whose developmental age is birth–6 yr; assesses language, sensorimotor function, activities of daily living, and preacademic and social-emotional performance.	
<i>Manual of Developmental Diagnosis</i> (Knobloch, Stevens, & Malone, 1980)	Adaptive, gross motor, fine motor, language, and personal-social behaviors.	Provides examples of developmental skills.
<i>Developmental Profile 3</i> (DP-3; Alpern, 2007)	Used to evaluate a child's functioning and risk of delayed development in five key areas: physical age, self-help age, social age, academic age, and communication age.	Assesses development in the following areas respectively: muscle coordination and sequential motor skills; ability to cope independently; interpersonal abilities, emotional needs; intellectual abilities and prerequisite skills; expressive and receptive communication skills.
<i>Developmental Programming for Infants and Young Children</i> (Moersch & Schafer, 1981)	Assesses function and facilitates development of children in five areas: perceptual and fine motor, cognition, language, social and emotional skills, and gross motor skills.	Provides direct transition to intervention goals and programming.
<i>Early Intervention Developmental Profile</i> (Rogers et al., 1981)	Perceptual and fine motor, cognition, language, social-emotional, self-care, and gross motor domains.	The motor scales are strengths of this scale; comprehensive developmental coverage, intended for use in a team approach; graphic profile of children's abilities; limited number of items at each age range; desirable for screening.
<i>Early Learning Accomplishment Profile</i> (E-LAP; Glover, Priminger, & Sanford, 1988)	Birth–36 mo; cognition, language, communication, adaptive behavior, social and emotional, motor skills.	Criterion-referenced assessment; especially useful in educational settings.
<i>Griffiths' Mental Developmental Scale</i> (Griffiths, 1954)	Locomotor, personal-social, hearing and speech, eye and hand coordination and performance.	Designed for use with children who have delays and deficits; contains the Abilities of Babies Subtest for assessment during the first 2 yr; includes information on performance of children with various handicaps; comparisons of client can be made to children with similar deficits; practical items relate to everyday activities; a general intelligence quotient may be derived; test administration may be limited by the many perceptual motor items that are timed; normed on the British population.
<i>Hawaii Early Learning Profile</i> (Furuno et al., 1994)	Cognitive, language, fine and gross motor, self-help, and social.	Performance is rated on four levels of mastery, rather than pass-fail; provides sequential approach to a Piagetian assessment of cognition particularly during the first 2 yr; sensitive to attachment and bonding behaviors; provides a good number of behaviors to assess; readily integrates into intervention programs.
<i>Infant Developmental Screening Scale</i> (Proctor, 1995)	Screens for developmental delays in six domains: habituation, attention, interaction, motor, physiological movements, and reflexes.	Useful for hospital-based practice with infants.

Scale	Areas Assessed	Comment
<i>Infant Intelligence Scale</i> (Cattell, 1960)	Sensorimotor skills, cognitive, psychomotor, and social.	Very similar to the Bayley, although not as comprehensive; additional items are provided if one item is administered in error; designed to be administered by teachers and instructional personnel.
<i>The Rossetti Infant-Toddler Language Scale</i> (Rossetti, 1990)	Birth–3 yr; areas assessed include play, interaction, attachment, gesture, pragmatics, language comprehension, and expression.	Includes parent questionnaire and test protocol to gather observed, elicited, and parent-report information; also includes a vocabulary checklist for comprehension and production.
<i>Mehrabian and Williams Scale</i> (Mehrabian & Williams, 1971)	Denotation and representational ability, linguistic and nonverbal communication abilities, domains of denotation and representation, observing response, reciprocal assimilation, object stability, imitation, and causality.	Gives level of cognitive development in months; provides assessment framework for the development of nonverbal behaviors and for the cognitive relationship between early “motor gestural” and later linguistic development.
<i>Mullen Scales of Early Learning</i> (Mullen, 1995)	Five brief scales that measure gross motor skills, visual-reception skills, fine motor skills, expressive and receptive language.	Provides examiner with a good picture of early cognitive and motor development; for each scale there is a T-score, percentile, and an age-equivalent score.
<i>Reynell Developmental Language Scales III</i> (Edwards et al., 1999)	Social adaptation, sensorimotor understanding, exploration of environment, response to sound and verbal comprehension, vocalization and expressive language (structure), expressive language (vocabulary and content), and communication.	Designed specifically to assess visually impaired children with additional handicapping conditions; provides norms for sighted, partially sighted, and totally blind children; divides expressive language testing into structure and content areas.
<i>The Portage Guide: Birth to Six</i> (Portage Project, 2003)	General development.	Set of tools for assessment and curriculum planning. One set of materials for birth to 3 yr. Each set of materials includes Tool for Observation and Planning (TOP) Assessment, spiral bound set of Activity and Routines Resource books corresponding to each TOP item, and User’s Guide.
<i>Schedule of Growing Skills, Second Edition</i> (Bellman, Lingam, & Auckett, 1996)	Assesses a range of areas for identification of normal or delayed development.	A rapid and reliable standardized assessment of child development; based on recent data from UK health surveillance.
<i>Syracuse Dynamic Assessment for Birth to Three</i> (SDA; Ensher et al., 1998)	Evaluates development of neuromotor sensation, perception, cognition, language, communication, social emotional behavior, and adaptive behavior, with priority to an integrated assessment of the whole child in the most familiar and natural contexts.	Play-based assessment of early development.
<i>Test of Pretend Play</i> (ToPP; Lewis & Boucher, 1999)	Ages 1–6 yr; measures a child’s ability to play symbolically in structured play conditions and in free play conditions.	Measures conceptual development, ability to use symbols, emotional status, and imagination and creativity.
<i>The Vulpe Assessment Battery—Revised</i> (VAB-R; Vulpe, 1997)	Birth–6 yr; object, body, shape, size, and space concepts; visual memory; auditory discrimination; auditory attention; comprehension; memory; cause-effect or means-ends behaviors; categorizing and combining schema.	Comprehensive, process-oriented, criterion-referenced assessment that emphasizes children’s functional abilities; the VAB-R provides a systematic interactive assessment/analysis of several key developmental domains to identify children who may be at risk of educational failure.
<i>Vineland Adaptive Behavior Scales, Second Edition</i> (Vineland-II; Sparrow, Balla, & Cicchetti, 2005)	Expressive and receptive communication, socialization, daily living, motor.	Extremely well-standardized with norming groups containing normal and handicapped individuals. Structured interview format.

Infant Feeding Assessment Instruments

Instrument	Description
<i>Clinical Feeding Evaluation of Infants</i> (Wolf & Glass, 1992a)	Provides a checklist for recording behaviors as well as a description of normal oral movement patterns.
<i>Early Feeding Skills Assessment</i> (Thoyre, Shaker, & Pridham, 2005)	A checklist for assessing infant readiness for oral feeding.
<i>Feeding Flow Sheet</i> (VandenBerg, 1990)	Used to document feeding progress during NICU stay.
<i>Feeding Assessment</i> (Morris & Klein, 2000)	Provides a questionnaire in both English and Spanish that the clinician can use with whoever is feeding the infant, whether parent or medical staff, and also provides guidance in developing a treatment plan.
<i>The Infant Breastfeeding Assessment Tool</i> (IBFAT; Matthews, 1988)	Used by parent or medical professional to measure infant's rooting, fixing, and sucking behaviors.
<i>LATCH: A Breastfeeding Charting System and Documentation Tool</i> (Jensen, Wallace, & Kelsay, 1994)	Consists of a scale for evaluating breastfeeding.
<i>The Mother-Baby Assessment</i> (MBA; Mulford, 1992)	Used to assess both maternal and neonatal breastfeeding behaviors.
<i>Neonatal Oral-Motor Assessment Scale</i> (Palmer, Crawley, & Blanco, 1993)	Includes both oral-motor evaluation and checklist for scoring normal and disordered feeding movements.
<i>Newborn Individualized Developmental Care and Assessment Program</i> (NIDCAP; Als, 2009)	Provides procedures for observing and summarizing natural infant behavior before, during, and after caregiving, and provides guidelines for developing behavioral goals on the basis of the observation.
<i>Oral Motor Assessment</i> (Sleight & Niman, 1984)	Developed for use with Down syndrome babies, but may be used with infants who have a variety of handicaps.
<i>Preschool Oral Motor Examination</i> (Sheppard, 1987)	Involves clinical direct assessment of motor and feeding behaviors.
<i>Pre-Speech Assessment Scale</i> (Morris, 1982)	Assesses a range of behaviors in addition to feeding, including respiration and vocalization, and provides an extensive questionnaire to be used with parents; also contains a wealth of information on normal and atypical prespeech and feeding development.
<i>Preterm Infant Breastfeeding Behavior Scale</i> (Nyquist, Sjoden, & Ewald, 1999)	Used to assess breastfeeding behaviors in preterm infants.
<i>Systematic Assessment of the Infant at the Breast</i> (SAIB; Shrager & Bocar, 1990)	Used to evaluate the infant's contribution to breastfeeding.

How Can We Help?

APPENDIX 6-5

Family Name: _____ Date: _____

Children and families receiving early intervention services have their own strengths and needs. Please use this form to help us know how we can be most useful to your family. We know that your needs will change from time to time and that this will be just a beginning in helping us to plan together. Answer only those questions that you think will help us to know how we can be most helpful to you and your family.

What pleases you most about your child?

What worries you most about your child?

What kind of help or information about your child do you need?

Are there things that you feel are going well for your family and child right now?

In the next several months, I would like my child to be able to . . .

Besides my family, other people I would like to include in the assessment and planning meeting for my child and family are . . .

In the next several months, I would like my family to . . .

Help planning for the future/transition:			
Eligibility and the public school special education process	_____	_____	_____
Eligibility, legal rights, parent's role	_____	_____	_____
Visiting other service settings	_____	_____	_____
Determining the best setting for my child	_____	_____	_____
Other:	_____	_____	_____

Please tell us the other ways we might be able to help:

The early intervention program can provide services to help you help your baby grow and develop. Families often need many services we cannot provide. When that happens, your case manager will help you find out how to get other community services.

Considerations in Feeding Older Prelinguistic Children

FOOD CHOICE

1. Sweet, sour, salty, or citrus foods tend to increase saliva; may be avoided for children with excessive drooling.
2. Milk tends to thicken saliva; broth tends to thin it.
3. Thin liquids are hard to manage orally; thicker liquids such as shakes or “smoothies” are easier to swallow.
4. Combinations of textures, such as soup with noodles, are hard to handle; they should be blended.
5. Slightly cooked vegetables are easier to chew than raw ones.
6. Avoid foods that could block the airway, such as hot dogs, foods with skin, unmashed grapes, and food in chunks.
7. Keep cold foods cold and hot foods hot so that the child can experience temperature differences; be careful not to overstimulate child with foods that are very hot or very cold.
8. A balanced diet is a must for any child’s health. Vitamin supplements may be necessary and can be added to food.

EQUIPMENT FOR FEEDING

1. Towels and washcloths for cleaning child.
2. Teflon-coated spoon with a shallow bowl to prevent pain if child bites hard.
3. Cup with soft plastic rim; cup should be as big around as child’s mouth is when open.
4. Equipment to maintain food temperature if feeding takes a long time.

POSITIONING

1. Hips and knees at 90-degree angles when seated.
2. Feet supported.
3. Shoulders slightly forward and arms supported.
4. Spine straight.
5. Head at midline and slightly forward.
6. Knees slightly apart.

DEVELOPING CUP-DRINKING SKILLS

1. Introduce cup outside of mealtime in playful situations.
2. Let child play with empty cup.
3. Rub a preferred taste on rim of cup and allow child to mouth it.
4. Introduce thickened liquid in cup, resting cup on lower lip in front of teeth; do not tip at more than a 20-degree angle. Be sure lips are closed before beginning.
5. Let child use upper lip to suck liquid from cup; be careful not to dump liquid in the child’s mouth.
6. To increase stability and facilitate mouth closures and upper lip movement, place middle finger under chin and gently push up while placing index finger or thumb on bottom edge of lower lip and gently pushing up.

DEVELOPING SPOON-FEEDING SKILLS

1. Use adaptive positioning for comfort and stability.
2. Introduce spoon outside mealtime in playful situation, such as pretending to feed doll.
3. Let child play with empty spoon.
4. When child tolerates spoon, dip it in food with a preferred taste.
5. Present spoon to lips or front of mouth. Let child use upper lip movement to remove food from spoon. Do not dump food in child’s mouth.
6. If tongue protrudes or child shows low facial tone, apply pressure down on middle of tongue with the spoon and withdraw it at a neutral angle, being careful not to scrape the spoon upward.
7. Use support to jaw or chin to increase stability, permit graduated jaw movement, and allow child to use upper lip movement to close on spoon.
8. When child accepts food from spoon, gradually increase textures presented.

DEVELOPING CHEWING SKILLS

1. Stimulate a munching pattern by presenting crunchy solid foods between molar surfaces. Look for up-and-down movement of the jaw.
2. Facilitate lateral tongue and jaw movements by stroking the side of the tongue with a solid food, then place the food between the molar surfaces.
3. Stimulate chewing during eating by rubbing the child's cheeks, one at a time, in a circular motion.
4. Provide jaw and chin support (as previously described) to reduce tongue protrusion and facilitate graduated jaw movement.
5. As child develops more control, place food closer to front of mouth.

CAUTIONS

1. The possibility of choking is always present. Practice feeding techniques, use care in choosing foods that will be easy for child to manage orally, and know first aid procedures in case choking occurs.
2. Seizures may occur during eating. If they do, stop feeding and wait until seizure is under control. Check to see whether any food is in mouth during and after seizure.
3. Look for abnormal feeding behaviors, such as those identified by Jaffe (1989) and listed in the following:
 - a. **Tongue thrust:** abnormal protrusion of tongue.
 - b. **Tongue retraction:** strong pulling back of tongue to pharyngeal space.
 - c. **Jaw thrust:** abnormally forceful downward extension of mandible.
 - d. **Lip retraction:** drawing the lips back so that they make a tight line over the mouth.
 - e. **Lip pursing:** a tight protrusion of the lips.
 - f. **Tonic bite reflex:** an abnormally strong closure of the teeth or gums when stimulated.
 - g. **Jaw clenching:** an abnormally tight closure of the mouth.

If these occur, specialized physiological feeding assessments may be necessary.

Adapted from Hall, S., Circello, N. Reed, P., & Hylton, J. (1987). *Considerations for feeding children who have a neuromuscular disorder*. Portland, OR: CARC Publications; McGowan, J., & Kerwin, M. (1993). Oral motor and feeding problems. In K. Bleile (Ed.), *The care of children with long-term tracheostomies* (pp. 157-19d). San Diego, CA: Singular Publishing Group.

Training Resources for Parents of Preintentional Infants

Resource	Comments
<i>Baby Signals</i> (Lynch-Fraser & Tiegerman, 1987)	Helps parents learn to identify infant states and learning styles.
<i>The Carolina Curriculum for Infants and Toddlers with Special Needs—Third Edition</i> (Johnson-Martin, Hacker, & Attermeier, 2004)	Provides comprehensive information on facilitating feeding and communicative development for infants and toddlers with a variety of handicapping conditions.
<i>Curriculum Guide: Hearing-Impaired Children—Birth to Three Years—and Their Parents</i> (Northcott, 1977)	Comprehensive infant program that focuses on home-centered, parent-guided, natural language approach to learning that is based on child's daily activities.
<i>Developmental Communication Curriculum</i> (Hanna, Lippert, & Harris, 1982)	Curriculum intended to help extend prelinguistic communication skills on which language is based; uses play as natural context for learning; includes parent information.
<i>Developmental Play Group Guide</i> (Browne, Jarrett, Hvey-Lewis, & Freund, 1997)	Manual containing group-lesson plans to give parents the information they need to guide the development of their birth to 12-month-old infants; lessons cover communication, cognition, and developmental play intervention.
<i>Ecological Communication (ECO): Becoming partners with children: From play to conversation</i> (MacDonald, 1989)	Helps parents establish a balanced, responsive, and matched social relationship with preverbal children.
<i>Exceptional Children Conference Papers: Parent Participation in Early Childhood Education</i> (Exceptional Children, 1969)	One area covered is programs for training mothers to instruct their infants at home.
<i>Family Administered Neonatal Activities</i> (Cordone & Gilkerson, 1989)	Involves parents in observing and interpreting newborn's actions and reactions.
<i>Hanen Early Language Parent Program</i> (Girolametto, Greenberg, & Manolson, 1986)	Teaches families to develop dialogue skills by responding contingently to children and to increase opportunities for communication by planning play activities with communication goals in mind.
<i>Illinois Early Learning Project Tip Sheets: Language Arts</i> (Illinois Early Learning Project, 2003)	Easy-printing pages are available as Web pages and as PDF files. Tip sheets related to promoting pre-literacy skills and conversation.
<i>Infant Learning: A Cognitive, Linguistic Intervention Strategy</i> (Dunst, 1981)	Intended for use by teachers, therapists, and child-care workers; three phases are response-contingent behaviors, sensorimotor abilities, and early cognitive-linguistic abilities.
<i>It Takes Two To Talk: A Practical Guide for Parents of Children with Language Delays, Third Edition</i> (Pepper & Weitzman, 2004)	Helps parents of children with language delays to promote their child's communication and language development in everyday conversations, daily routines, play activities, music, book reading, and art activities.
<i>Learning Language and Loving It, Second Edition</i> (Weitzman & Greenbar, 2002)	Provides guidelines for developing language in everyday activities. French and Korean version available for 1st ed.
<i>Making the Connections that Help Children Communicate</i> (Girolametto, Greenberg, & Manolson, 1986)	Summarizes the Hanen approach in a workbook format. Teaching aid to support a 1-day workshop for parents awaiting speech-language pathology services.
<i>More Than Words: Helping Parents Promote Communication and Social Skills in Children with Autism Spectrum Disorder</i> (Sussman, 1999)	Guidebook for parents of children with autistic spectrum disorder. Contains descriptions of strategies drawn from current research, which are known to help children with autism develop more advanced communication skills. See accompanying videos listed in Appendix 6-8 .
<i>Parent Articles for Early Intervention</i> (Dunn Klein, 1990)	102 articles that provide parents with practical information on therapeutic ways to interact with their special-needs child.
<i>Parenting a Hearing-Impaired Child</i> (Northcott, 1973)	Systems approach to parental participation, aids for parents.
<i>Parent-Infant Communication, Fourth Edition</i> (Scuyler & Sowers, 1998)	Curriculum for hearing-impaired with objectives in auditory development, presymbolic communication, and receptive and expressive language; helps parents become accurate reporters and coordinate services for their child.
<i>Promoting Communication in Infants and Young Children</i> (Quick & O'Neal, 1997)	500 activities and suggestions for promoting communication development in infants and young children.

Resource	Comments
<i>Reach Out and Teach</i> (Ferrell, 1985)	Two volumes: <i>Parent Handbook</i> and <i>Reach</i> ; contains chapter on "Daily Living and Communicating" (eating skills are a topic in this chapter).
<i>Since Owen: Parent-to-Parent Guide for Care of the Disabled Child</i> (Callanan, 1990)	Discusses raising a disabled child from before birth through life in the adult world.
<i>Speech and Language Handouts Resource Guide, Second Edition</i> (Brooks & Hartung, 2000)	Tear-off sheets that clinicians, physicians, speech pathologists, pediatricians, and others can give to parents who are concerned about their child's speech and language development. Spanish edition also available.
<i>Talk to Me: A Language Guide for Parents of Blind Children</i> and <i>Talk to Me II: Common Concerns</i> (Kekelis, Chernus-Mansfield, & Hayashi, 1984)	Two pamphlets with some suggestions to encourage language development.
<i>Talk! Talk! Talk! Tools to Facilitate Language</i> (Muir et al., 2000)	Birth to 10 yr; strategies for listening and talking to teach to caregivers.
<i>Take Home: Preschool Language Development</i> (Drake, 1998)	Designed for parents of children from 1 to 6 yr of age who have communication disorders. Includes lesson plans and activities.
<i>Teach Your Child to Talk—Revised</i> (Pushaw, 1976)	Manual; slide; cassette tape; movie; parent handbook; and <i>Teach Me to Talk</i> , a booklet for parents of newborns.
<i>The Exceptional Parent</i> (magazine)	Practical information for parents of handicapped children. Also see www.eparent.com .
<i>The New Portage Guide</i> (Portage Project, 2003)	For mental ages birth to 5 yr; two parts: checklist of behaviors and card file; five developmental areas: cognitive, self-help, motor, language, socialization. Also available in Spanish.
"Tips for Parents" (Lawrence, 1991)	Tips for feeding disabled children who have a G-tube or who are developmentally delayed.
"Training Prerequisites to Verbal Behavior" in <i>Systematic instruction of the moderately and severely handicapped</i> (Bricker & Dennison, 1978)	Gives behaviors preliminary to formal language development; strategies included for on-task behavior, imitation, discriminate use of objects, and word recognition.
<i>Transactional Intervention Program</i> (Mahoney & Poweel, 1986)	A home-based program that helps parents to develop a responsive style of interaction with children with developmental delays from birth to 3 yr.
<i>Understanding My Signals</i> (Hussey-Gardner, 1999).	Pamphlets designed to help parents of premature infants.
<i>You Make The Difference: In Helping Your Child Learn</i> (Manolson, Ward, & Dodington, 1995)	Helps parents connect in encouraging a child's self-esteem and learning.
<i>Your Child's Speech & Language</i> (Brooks, 1978)	Provides information about speech and language development from infancy through 5 yr.
<i>When Your Child Has a Disability: The Complete Sourcebook of Daily and Medical Care, Revised</i> (Batshaw, 2007)	Offers expert advice on a range of issues, including doctors, care techniques, and fulfilling educational requirements.

Videos for Training Parents of Infants

Title	Source	Comments
<i>Baby Speech: An Adult's Guide to Helping Your Little One Communicate</i> (Castillo & Ramsay, 2001)	Chatterbox Communications Available through Speech Bin	40 minutes. Teaches parents simple techniques to promote speech.
<i>Communicating Effectively with Young Children</i> (Communication Therapy Skill Builders, n.d.)	Communication Therapy Skill Builders (A Division of the Psychological Corporation) 555 Academic Court San Antonio, TX 78204	Gives families effective communication strategies for use with children who have communicative, physical, social, or cognitive impairments. Teaches, illustrates, and models routines and communication strategies for parental interaction with the child.
<i>Family-Guided Activity-Based Intervention for Infants and Toddlers</i> (Cripe & Crabtree, 1995)	Brookes Publishing PO Box 10624 Baltimore, MD 21285	Helps parents with daily routines and activities to foster skill development in young children with special needs.
<i>Feeding Skills: Your Baby's Early Years</i> (Arens, 1985)	Churchill Films 662 North Robertson Blvd. Los Angeles, CA 90069	How and why babies feed as they do; breastfeeding, transition to spoon feeding, home preparation of food, finger feeding.
<i>Growing Together</i> (AGS Media, 1992)	American Guidance Service 4201 Woodland Rd. Circle Pines, MN 55014	Designed to provide teen parents with practical information on understanding and caring for infants.
<i>Human Development: The First Two-and-One-Half Years: Program 7—Language</i> (Concept Media, n.d.)	Concept Media PO Box 19542 Irvine, CA 92713	Stages in child language development are illustrated: cries of hunger, discomfort, fear; cooing, babbling, first words.
<i>Human Development: A New Look at the Infant: Program 4—Infant Communication</i> (Concept Media, n.d.)	Concept Media PO Box 19542 Irvine, CA 92713	Describes process of communication, three components that form basic structure of communication, and forerunners of full-fledged communication.
<i>Human Development: The First Two-and-One-Half Years: Program 3—The Development of Understanding</i> (Concept Media, n.d.)	Concept Media PO Box 19542 Irvine, CA 92713	Piaget's observations of infant development are discussed; infants actively seek information and absorb information gained.
<i>Making the Most of Early Communication: Strategies for Supporting Communication with Infants, Toddlers, and Preschoolers Whose Multiple Disabilities Include Vision and Hearing Loss</i> (Chen & Schachter, 1997)	Chen, Deborah, & Schachter, Pamela Haag AFB Press American Foundation for the Blind PO Box 1020 Sewickey, PA	This 37-minute video demonstrates selected interventions to assist infants and toddlers with multiple disabilities, including vision and hearing loss, in developing early communication and other skills.
<i>More Than Words</i> (introductory video and teaching tape) (Sussman, 1999)	Hanen Centre Suite 515, 1075 Bay Street Toronto, Ontario Canada M5S 2B1 www.hanen.org	Demonstrations of techniques described in the guidebook (see Appendix 6-7). Introductory video is 20 min; teaching video is 120 min.
<i>Observing and Enhancing Communication Skills: For Individuals with Multisensory Impairments</i> (Rowland, 2001)	Concept Media PO Box 19542 Irvine, CA 92713	Teaches parents how to observe, analyze, and enhance communication skills in children who have vision and hearing impairments or multiple disabilities.
<i>On This Journey Together</i> (4-video set) (Family First & Ohio Department of Mental Retardation, n.d.)	Family First and Ohio Department of Mental Retardation and Developmental Disabilities	Parents speak about their experiences in raising a child with developmental disabilities.

Title	Source	Comments
<i>Premie Potential: Improving the NICU Environment of the Premature Infant</i> (Communication Skill Builders, n.d.)	Communication Skill Builders 3830 E. Bellevue PO Box 42050-P93 Tucson, AZ 85733	Gives how-to's on approaching the infant, determining levels of stimulation, teaching parents interaction skills, making the infant's world as pleasant and nurturing as possible.
<i>Sharing Books with Babies: Promoting Early Literacy in Early Care and Education</i> (Kaplan-Sanoff, 2002)	Margot Kaplan-Sanoff Boston Medical Center One Boston Medical Center Place Maternity 5 Boston, MA 02118	The video demonstrates the following: (1) the developmental stages of early literacy growth in the first 5 yr of life, (2) examples of early literacy-promoting activities which can be used throughout the day, and (3) literacy rich home- and center-based environments for infants, toddlers, and preschoolers.
<i>Successfully Parenting Your Baby with Special Needs: Early Intervention for Ages Birth to Three</i> (Hanlon, 1999)	Produced by Grace Hanlon, M.S. 1999, 60 minutes Brookes Publishing PO Box 10624 Baltimore, MD 21285	60 min. Gives first-time parents of infants with special needs a full introduction to the early intervention process. Covers diagnoses and referral, evaluation criteria, IFSPs, community resources, and transitions.
<i>Your Baby and You: Understanding Your Baby's Behavior</i> (Communication Skill Builders, n.d.)	Communication Skill Builders 3830 E. Bellevue PO Box 42050-P93 Tucson, AZ 85733	Helps parents understand and respond to their infant in the NICU; shows parents what to expect as their baby develops and how they can provide a sensitive environment; available in English and Spanish.

Assessment and Intervention for Emerging Language

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Discuss the principles of family-centered practice for toddlers.
2. Describe the communication skills of typical toddlers.
3. Discuss methods of screening, evaluation, and assessment for emerging language.
4. Describe strategies for using assessment information in treatment planning at the emerging language stage.
5. List appropriate goals, procedures, and contexts for treatment of children at the emerging language stage.
6. Discuss the issues relevant to communication programming for older, severely impaired clients with emerging language.
7. List assessment and treatment issues for toddlers with autism spectrum disorder (ASD).

Joey had been a difficult baby. He'd cry inconsolably for hours on end, and the only way his parents could calm him was to put him in his car seat and drive around. Even at 6 months, when most babies have outgrown their colicky stage, Joey continued to be extremely irritable and unable to find comfort in his parents' cuddling and attention. He sat up at only 4 months, walked at 11 months, and at that time began to take an interest in objects that bounced or sprang. He spent long periods playing with rubber bands. He was quiet, too, and didn't seem to babble as much as his parents' friends' babies. When he was 18 months old, he said a few phrases, usually echoes of what he'd heard before, such as "Go, dog, go," or "I'm lovin' it." He didn't seem to be learning a lot of new words, though, and he didn't seem to listen when people talked to him or even turn when they called his name. Still, he was very good at letting people know what he wanted. He would take adults' hands and lead them to things. It didn't seem to matter much who the adult was, though. Once he got what he wanted, he was content to play with it alone for long periods. Everyone told his parents there was nothing to worry about; Joey was just a "late bloomer." When he had his second birthday, Joey's mother took him to the pediatrician for a checkup. The doctor asked about Joey's speech, and his mother reported that he said a few things. She commented that Joey's brother Bobby had talked a blue streak when he was

2 and said she remembered taking him to an amusement park for his second birthday present. She recalled that he'd known the names of all the animals on the merry-go-round and had labeled each one as it went past. She knew that all children were different, but maybe Joey really was slow in his speech. She expressed her concern to the doctor. Her pediatrician recommended that Joey have his hearing tested. When the test came back within normal limits, the pediatrician reassured her that Joey would probably grow out of his slow start in speech.

Joey's story probably sounds familiar. Everyone knows a toddler who was late to begin talking, and everyone knows that most of them do eventually "catch up." We've all heard stories about how Einstein didn't start talking until he was 4. Popular wisdom, common sense, and most people's experience support Joey's pediatrician's claim that Joey will grow out of his early delay. However, for some toddlers, early lags in the development of speech foretell more long-lasting problems. Some of the other behaviors Joey has displayed throughout his development, such as his early inconsolability, his inordinate interest in particular kinds of objects, his lack of social awareness, and his use of echoed phrases, may suggest greater risk for long-term disability. How can we decide which toddlers with slow language development are at risk for long-term deficits? What should we do about them? These are some of the questions this chapter addresses.

This chapter also discusses assessment and management issues for youngsters identified as at-risk for communication disorders during infancy. These children will probably begin to evidence their delays during the 18- to 36-month period that comprises the toddler age range. This is the time during which children normally begin speaking, producing single words, and beginning to combine words into two-word utterances and simple sentences. If a child is going to have problems developing language, those problems will probably become evident in the toddler stage.

Finally, the approaches and principles discussed in this chapter will be appropriate for assessing and treating children of any age whose language is just emerging. Preschoolers with language disorders and older children and adolescents with severe deficits in language learning also can be seen to function in this stage. In summary, then, this chapter addresses methods of assessment and intervention for any client just beginning to use symbolic forms of expression.

Remember that when we discuss children at this beginning language level we mean children whose *developmental level* is 18 to 36 months. Some toddlers who do not talk, particularly those identified as at-risk during infancy, will not yet function at this

developmental level. Using the general developmental assessment tools outlined in this chapter, a toddler's developmental level can be described. When developmental assessment indicates that a child is functioning below a 12- to 18-month level, even if he or she is chronologically older, management should continue to follow the guidelines given in Chapter 6. Only when general developmental level reaches 18 months or so should the direct communication intervention that is discussed in this chapter be considered.

We'll refer to this period as the *emerging language* (EL) stage, to suggest that this is the period in which conventional words are just beginning to appear as viable forms of communication. Children may enter the emerging language stage at any age, of course, just as the child with prelinguistic communication can be of any age. For normally developing children, this stage corresponds to the "toddler" age range, or an 18- to 36-month developmental level. Let's look first at issues in assessment and intervention for children who are chronologically close to this age range. Then we'll discuss issues for older children functioning as emerging communicators.

ISSUES IN EARLY ASSESSMENT AND INTERVENTION

Screening and Eligibility for Services

The Individuals with Disabilities Education Act (IDEA) 2004 provides for the development of programs for infants and toddlers with disabilities, as we saw in Chapter 6. One of the intents of this law is to affect both primary and secondary prevention by allowing children with disabilities to be identified as early as possible and to receive prompt intervention. Evaluations of early intervention efforts, such as Camilli et al. (2010); Guralnick (1997); McLean and Cripe's (1997); the National Research Council (2001); and Reynolds, Want, and Wahlberg's (2003) comprehensive reviews, have concluded that early intervention is effective, often resulting in faster gains than those seen in normal development, so the justification for intervening in these cases is quite compelling. The law's impact on clinical practice for speech-language pathologists (SLPs), then, is that more and more children younger than 3 are being identified and referred for communication evaluation, assessment, and intervention. SLPs employed in a variety of settings—in hospitals, schools, nonprofit agencies, and private practice—will be seeing this birth-to-3 population.

Children we will serve include those born with known risk factors who were referred for speech and language services during infancy. These are children with identifiable syndromes of developmental disorder, such as Down syndrome or fetal alcohol syndrome; those with hearing impairments identified in infancy; and those with neurological involvement, such as cerebral palsy or prenatal drug exposure. For these children, no screening or evaluation for eligibility will be necessary.

Other children, though, may also present as toddlers with apparently specific language delays. These children may come to us through Child Find or other referral sources or simply because parents are concerned about their development. Some of these toddlers may turn out to have related disorders, such as hearing impairment, that were not previously detected, or less obvious forms of developmental disorder, such as fetal alcohol effects or fragile X syndrome. Some may have suffered from early acquired disorders secondary to diseases such as encephalitis or from trauma or abuse. Some, like Joey, will have disorders on the autism

spectrum. Some will have no evident correlates of their slow language development, but present with circumscribed deficits in language skills that place them at risk for developmental language disorder or learning disabilities at school age. For these children, screening may be the first step in the evaluation process.

In recent years, several screening instruments have been developed and refined to help clinicians make a general determination about whether further evaluation for communication is needed. Two parent-report measures, which focus primarily on vocabulary size, have been prominent. The *MacArthur-Bates Communication Development Inventory* (CDI) (Fenson et al., 2007) has been shown in a variety of studies (e.g., Girolametto, Wiggins, Smyth, Weitzman, & Pearce, 2001; Heilmann, Weismer, Evans, & Hollar, 2005; Lyytinen, Eklund, & Lyytinen, 2003; Weismer & Evans, 2002) to be effective in identifying toddlers with low language skills, and to be valid for both English- and Spanish-speaking toddlers (Marchman & Martinez-Sussman, 2002). The *Language Development Survey* (LDS; Rescorla, 1989) has also been shown to be valid, reliable, sensitive, and specific for this purpose (Klee, Pearce, & Carson, 2000; Rescorla & Achenbach, 2002; Rescorla & Alley, 2001). Rescorla et al. (2005) showed, too, that rankings on the LDS and CDI were highly correlated, suggesting they are equally valid screening tools. Klee et al. (2000) also reported that the number of false positive results decreased when questions about ear infections and whether parents were concerned about the child's language development were added to the LDS criterion of less than a 50-word expressive vocabulary or no word combinations for 24-month-olds. Although there are no current mandates for universal screening for toddlers for language delay, these instruments can be given to parents who have concerns about their children's language development, as a first step toward deciding whether further evaluation is needed. Clinicians can also distribute these instruments to local pediatricians. In fact, the American Academy of Pediatrics recommends screening for toddlers to detect autism spectrum disorder (ASD), although the brief checklists used for this purpose are likely to detect children with language disorders, as well. The SLP can work with pediatricians' offices to review these screeners to decide whether any referrals to birth-to-3 services should be made.

For toddlers who have delays in cognition, motor, social, and other areas besides language, evaluation is clearly warranted. But not all would agree that an otherwise typical child of 18 to 36 months who fails to begin talking or who talks very little is evidencing significant delay. Many professionals both in and outside the field of language pathology would hesitate to label a child with no other difficulties outside of speech development as "language disordered" before the third or even the fourth birthday (Rescorla & Lee, 2001), for just the reasons mentioned earlier—that many children who are slow to start talking eventually catch up. Providing intervention at the 18- to 36-month level for such children would not be cost-effective. Early intervention, although known to be effective when necessary, is expensive. It is wise to conserve such resources for children who really need them.

So who needs them? Ellis and Thal (2008), Whitehurst and Fischel (1994), and Paul (1996, 1997a) have argued that, for children in the 18- to 36-month age range, the decision to intervene should be based on an accumulation of risk factors. They suggested that children with cognitive deficits, hearing impairments or chronic middle ear disease, social or preverbal communicative problems, dysfunctional families, risks associated with their birth histories, or family history of language and reading problems

(Bishop, Price, Dale, & Plomin, 2003; Lyytinen, Poikkeus, Laakso, Eklund, & Lyytinen, 2001; Zubrick et al., 2007) should receive high-priority for intervention. Brady, Marquis, Fleming, and McLean (2004); Campbell et al., (2003); McCathren, Yoder, and Warren (1999); Olswang, Rodriguez, and Timler (1998); and Paul and Roth (2011) suggested that additional factors, listed in Box 7-1, also be considered. In light of these suggestions, a detailed case history and comprehensive direct assessment of all these areas are important for any toddler referred for failure to begin talking. When a toddler with slow language development shows significant risk factors, intervention is clearly warranted. The goal of that intervention is secondary prevention—minimizing the effects of the delay on the acquisition of language.

There are a variety of standardized instruments that can be used to evaluate toddlers for eligibility for birth to 3 services. Generally, regulations require that children show impairments in at least two areas in order to be eligible for services; whether expressive and receptive language constitute two separate areas varies from state to state. Clinicians will need to be familiar with the guidelines for their particular locality. However, informed clinician opinion is always part of the evaluation process, so test scores alone will not be adequate to establish eligibility. Because more than one area of deficit is typically required for eligibility, instruments that sample

several areas of development are often used for this purpose. Some procedures that can be part of this evaluation are listed in Box 7-2.

For toddlers without other known risk factors who are simply slow to start talking, deciding whether to intervene is more difficult. Intervention for this group may accomplish facilitation, hastening development that would eventually happen on its own, rather than induction. Children who have learning disabilities often have histories of delayed language development (Butler & Silliman, 2002; Catts, 1997; Catts & Kamhi, 1986; Maxwell & Wallach, 1984; Steele, 2004; Tallal, 2003; Weiner, 1985). Even late talkers who perform within the normal range in language and literacy measures by age 5 or 6 (Paul & Fountain, 1999) begin to show deficits in literacy skills later in development (Rescorla, 2002), and there is a risk that these will persist into adolescence (Rescorla, 2009; Snowling, Adams, Bishop, & Stothard, 2001; Snowling & Bishop, 2000). Early language intervention may serve a secondary preventive function, then, helping to minimize later effects on learning even when the more basic oral language problems resolve. In addition, Robertson and Weismer (1999), for example, showed that intervention for late talkers not only increased their language skills but resulted in improvements in social skills and reductions in parental stress, so there may be other important secondary effects of supplying early intervention to these children.

BOX 7-1 Predictors and Risk Factors for Language Growth in Toddlers

PREDICTORS OF NEED FOR INTERVENTION

Language

1. Language production
 - Small vocabulary for age
 - Few verbs
 - Preponderance of general verbs (*make, go, get, do*)
 - More transitive verbs (that take a direct object: *hit ball*)
 - Few intransitive verbs (without direct object: *lie down*) and bitransitive verbs (that take both direct and indirect object: *give the ball to me*)
2. Language comprehension
 - Presence of 6-month comprehension delay
 - Comprehension deficit with large comprehension-production gap
3. Phonology
 - Few prelinguistic vocalizations
 - Limited number of consonants
 - Limited variety in babbling
 - Reduced rate of babbling
 - Fewer than 50% consonants correct (substitution of glottal consonants and back sounds for front)
 - Restricted syllable structure
 - Vowel errors
4. Imitation
 - Few spontaneous imitations
 - Reliance on direct modeling and prompting in imitation tasks

Nonlanguage

1. Play
 - Primarily manipulating and grouping
 - Little combinatorial or symbolic play

2. Gestures

Few communicative gestures, symbolic gestural sequences, or supplementary gestures (gestures that add meaning to words produced)

3. Social skills

Reduced rate of communication
Reduced range of expression of communication intentions
Behavior problems
Few conversational initiations
Interacts with adults more than peers
Difficulty gaining access to peer activities

RISK FACTORS FOR LANGUAGE DELAY

1. Males more vulnerable to delay than females
2. Otitis media
 - Prolonged periods of untreated otitis media
3. Family history
 - Family members with persistent language, reading, and learning problems
4. Parent characteristics:
 - Low maternal education
 - Low SES
 - More directive than responsive interactive style
 - Produces less talk contingent on child's productions
 - High parental concern

Developmental Assessment of Young Children (DAYC; Voress & Maddox, 1998)
Developmental Profile III (DP-III; Alpern, 2007)
Hawaii Early Learning Profile: 0–3 (HELP; Furuno et al., 1994)
Mullen Scales of Early Learning (Mullen, 1995)
Preschool Language Scale—Fifth Edition (PLS-5; Zimmerman, Steiner, & Pond, 2011)
The Vulpe Assessment Battery—Revised (VAB-R; Vulpe, 1997)
Vineland Adaptive Behavior Scales—II (Sparrow, Cicchetti, & Balla, 2005)

Paul (2000b) has argued that perhaps the best approach for late talkers without additional risk factors is to provide parent training in language facilitation techniques, rather than direct intervention. Girolametto, Pearce, and Weitzman (1996) and Peterson, Carta, and Greenwood (2005) showed that parents of late talkers could be trained to produce positive effects on the amount of child speech, the size of child vocabulary, and the number of multiword combinations.

Transition Planning

Hadden and Fowler (2000) discussed the importance of developing active coordination among agencies serving young children with disabilities in order to smooth their transition from early intervention to preschool programs. SLPs can play an important role in developing these interagency relationships. Prendeville and Ross-Allen (2002) outlined a variety of ways SLPs can be effective members of transition teams. These include the following:

- Providing families with information and support to participate in transition planning
- Setting aside time to work with team members from both early intervention and preschool service providers to prepare a timely transition plan
- Sharing information about adaptations, accommodations, resources, and developmentally appropriate activities with preschool staff
- Actively helping preschool staff prepare the necessary services and supports to promote successful preschool placement

Family-Centered Practice

Like children at the prelinguistic stage of development, children with emerging language still function primarily in the context of the family. Practice for this developmental level, too, must be

family-centered in order to succeed. Many of the same principles we discussed for infants apply to our work with toddlers. ASHA (2008) Guidelines for early intervention practice emphasize the need for family-centered practice in this area. Dempsey and Keen (2008); Dinnebeil and Hale (2003); Dunst, Boyd, Trivette, and Hamby (2002); and Polmanteer and Turbiville (2000) discuss some of the considerations that are primary in working with families in early intervention. These include the following:

- Spending time with the family to learn about their vision for the child and discussing what parents would like to see their child do as a result of intervention
- Finding out what families expect from the program at the outset and discussing expectations in order to come to a consensus about what is reasonable to expect
- Including the family's assessment of the child in the assessment report; writing the report in the words used by the family
- Including multiple ways for families to be involved in the child's program; providing choices and options
- Working together with families to choose natural environments as a source of learning opportunities
- Reviewing progress with families to make sure new skills are used consistently across natural environments
- Identifying important people with whom the child needs to practice communication skills
- Working with families to find ways to use children's interests to involve them in everyday learning opportunities
- Providing families with opportunities to be involved in both direct work with their child and acquiring new knowledge and skills for interacting with their child
- Enabling parents to decide on the correct balance for their family

Communicative Skills in Normally Speaking Toddlers

What do we mean by "normal language development" in toddlers? Considerable research in recent years has allowed us to flesh out the picture of what constitutes normal language skills in very young children, so that we can determine when development is falling behind. Paul and Shiffer (1991) and Wetherby, Cain, Yonclas, and Walker (1988) reported that children at about 18 months of age produced an average of two communicative acts per minute in interactive samples. The functions of these acts are usually to request objects or actions, to establish joint attention, or to engage in social interaction (Hulit & Howard, 2002; Wetherby et al., 2004). During the second year of life, many of these intentions are expressed not with words, but with gestures (Capone & McGregor, 2004) and vocalizations (Oller, 2000). By 24 months, children produce an average of five to seven communicative acts per minute (Chapman, 2000). The majority of these communicative acts consist of words or word combinations, although some nonverbal acts are still used. Between 18 and 24 months of age, then, children significantly increase their frequency of communication, both verbally and nonverbally, and move toward more frequent verbal expressions of intent.

Luinge et al. (2006) and Nelson (1973) showed that most middle-class toddlers were combining words into simple two-word sentences by 18 to 24 months; Roulstone, Loader, Northstone, and Beveridge (2002) reported that 78% of typically developing 25-month-olds were using multiword utterances. Luinge et al.

(2006) reported that 98% of 24- to 36-month-olds produced two-word sentences, 90% produced three-word sentences, and 84% produced four-word sentences at this age. Grove and Dockrell (2000) reviewed literature that demonstrates that there are predictable patterns in the ways words are first combined, with stable word orders that follow patterns in the adult language, and that the meanings expressed by children in their first “telegraphic” sentences conform to a small set of semantic relations.

Stoel-Gammon (1987, 2002) indicated that normally developing 24-month-olds produced at least 10 different consonants and were 70% correct in their consonant productions. Luinge et al. (2006) reported that over 75% of 24- to 36-month-olds are more than 50% intelligible. Speech samples of these toddlers included a variety of syllable shapes, including consonant-vowel (CV) and CVC, in virtually every child, and two-syllable words in the majority; the most frequent two-syllable form was the CVCV reduplicated syllable. McLeod, van Doorn, and Reed (2001) also showed that 2-year-olds are beginning to produce consonant clusters, although they may not always be correct relative to adult targets.

Detailing changes in expressive vocabulary size in the second and third years of life has been the focus of much recent research (e.g., Dale, 2005; Rescorla & Achenbach, 2002). Fenson et al. (2007) reported that average expressive vocabulary size at 18 months is about 110 words. Dale, Bates, Reznick, and Morisset (1989) have shown that, by 20 months, average productive lexicon size reaches 168 words. By 24 months, Fenson et al. found mean vocabulary size to be 312 words, and at 30 months, 546 words. Stoel-Gammon (1991) pointed out that there is a great deal of variability in lexicon size in young children, but that this variability decreases dramatically during the third year of life. At 18 months, the variability in vocabulary size is larger than the mean, so that more than 16% of children still have very few words at this age. However, by 24 months the average variation in vocabulary size is only half as large as the mean and 84% of children at this age have vocabularies larger than 150 words. At 30 months the standard deviation in vocabulary size is only 18% of the average lexicon size. This means that 84% of children at this age have vocabularies larger than 450 words. The degree to which a small expressive vocabulary represents a significant deficit increases drastically between 18 and 30 months of age.

Traditional wisdom has been that comprehension precedes production. Receptive vocabulary size is always larger than the size of the productive lexicon; this is true even for adults. For example, if you read the sentence, “Her proclivity for using long sentences in lectures drove her students to distraction,” you would no doubt comprehend the word *proclivity*. But if you were asked to come up with a synonym for *tendency* you might not be so likely to produce *proclivity*. The child’s comprehension of a first word is usually about 3 months ahead of the production of a first word, and comprehension of 50 different words usually occurs about 5 months before the productive lexicon reaches this size (Benedict, 1979).

In terms of sentences, though, comprehension is probably not so far ahead of production. Chapman (1978) argued that children in the 18- to 24-month age range probably understand only two to three words out of each sentence they hear (that is, about the same number of words per sentence that they are producing in their own speech). Luinge et al. (2006) found that over 90% of 12- to 24-month-olds understand two-word sentences and names for some body parts, but it is not until 24 to 36 months of age that the majority of children understand three-word sentences. The appearance of more sophisticated comprehension skills that

they often achieve is related to their ability to use nonlinguistic information to supplement their knowledge of language. These comprehension strategies allow the child to combine cues from gestures, facial expressions, and the way they know things usually happen with their understanding of words. The result is that children can appear to comprehend a long sentence such as, “Why don’t you go close that door for me?” by combining their knowledge of the meaning of *close* and *door* with their understanding that adults usually ask children to do things (Paul, 2000a; Shatz & Gelman, 1973; Thal & Flores, 2001).

The information presented here can help to guide us in determining whether a toddler is significantly behind in communicative skills. In some ways, this research may lead us to intervene more quickly than we might have earlier. The demonstration that children as young as 24 months communicate frequently, have large vocabularies, and are accurate in their phonological productions the great majority of the time may emphasize and make more obvious the deficits seen in children with slow communicative growth. In addition, Thal and Clancy (2001) show that the interaction between biological development and environmental input plays an important role in language acquisition, so that providing high-quality input can have significant effects on early development. Still, we want to use caution and remember the large variations seen in normal development. In this chapter we’ll look at some procedures that can be used to assess the various areas of communicative development in children with emerging language: symbolic play and gestural behavior, intentional communication, comprehension, phonology, and expressive language. We’ll then look at some guidelines for integrating these assessment data into the processes of deciding when and how to intervene with children at this developmental level.

Assessment of Communicative Skills in Children with Emerging Language

Multidisciplinary and Transdisciplinary Assessment

When children younger than 3 years are assessed by an evaluation team, the assessment may be multidisciplinary or transdisciplinary. In multidisciplinary assessment, each professional carries out a relatively independent assessment, exploring the issues relevant to his or her own discipline. The SLP assesses communication issues, the physical therapist assesses motor skills, and so on. The team comes together at the end of the assessment to report findings, talk with parents, and plan intervention. Many of the assessment procedures outlined in this chapter could be used in this model. They provide in-depth information that can be used not only to decide whether a client is significantly impaired but also to establish baseline function and identify intervention goals.

An alternative form of assessment used for children younger than 3 is the transdisciplinary approach (ASHA, 2008; Kritzing, Louw, & Rossetti, 2001; Linder, 1993; Rossetti, 2001), sometimes called “arena assessment.” Transdisciplinary or arena assessments involve the child’s interacting with just one adult, a “facilitator,” who performs some formal and informal assessments. The other members of the team, including the SLP, observe the facilitator’s interaction with the client. They may ask the facilitator to present certain tasks to the child, and they take notes on their observations of the child’s behavior in the situation, but they do not interact directly with the client. This approach is useful for looking at very young children who may have difficulty responding to a changing parade of unfamiliar adult faces. Many of the assessment

techniques we discuss in this section can be incorporated into transdisciplinary evaluation by having the SLP go over them with the facilitator before the client is seen and then by having the facilitator include them with his or her interactions with the child. For example, the SLP might ask the facilitator to do a play assessment or a communicative intention assessment (both of which are described in this chapter). The SLP could teach the procedures to the facilitator, gather the necessary materials, and explain the purpose of the assessment. During the interaction with the client, the SLP would observe and score the client's responses on a prepared worksheet and also would note any other relevant behaviors the client displays. Transdisciplinary assessment is generally used to decide whether a young child is eligible for early intervention services. Once eligibility for speech and language services has been established, the clinician can do more in-depth criterion-referenced assessments during the course of the intervention program if additional information is needed to establish baseline function and choose intervention goals.

Play and Gesture Assessment

Before deciding that a toddler has a communication problem, we want to be sure that the child has achieved a general developmental level consistent with the use of symbolic communication. This is a controversial area. Traditional Piagetian thinking on the relation between language and cognitive development held that children could not be expected to use symbolic language until they had achieved certain cognitive milestones, such as the understanding of object permanence, tool use, or symbolic play. A great deal of research on the relations between cognitive and language development (e.g., Tomasello, 2002; Witt, 1998) has suggested, though, that such simple prerequisite relations are not typically found in normal development. Thal (1991) explained that most researchers in this area do not believe that there is a general relationship between language and cognition. Instead there are what researchers call *local homologies*. Local homologies are specific relationships that occur at certain points in development. For example, Bates, Bretherton, Snyder, Shore, and Volterra (1980) have shown that in the single-word period, there is a strong relationship between the use of words as labels and the ability to demonstrate functional play, or to use objects in play for their conventional purposes, such as putting a toy telephone up to the ear. A little later, when children begin to combine words, this relationship decreases in strength. However, a relationship emerges between the ability to combine words and the ability to produce sequences of gestures in play, such as going through the series of motions to feed and bathe a doll. Later, this relationship, too, declines.

Current thinking about these findings (e.g., Casby, 2003a; Crais, Watson, & Baranek, 2009; Watt, Wetherby, & Shumway, 2006) suggests that although particular cognitive skills are not necessarily prerequisites for language development in general, certain behaviors that can be observed in a child's play and gestural behavior tend to go along with particular communicative developments. Brady et al. (2004) and McCathren et al. (1999) for example, showed that prelinguistic children with developmental disabilities who used symbolic play behaviors were likelier than those who did not to increase their rate of communication in an intervention program. If early symbolic behaviors are present, this would suggest that the language skill that normally appears along with them should be within the child's zone of proximal development and that it should be teachable. If the play and gestural skills are absent, as well as the language, then we might attempt to elicit both the play and language

skills in tandem, since their development seems to be parallel and they may reinforce or complement each other.

Assessing Play

Play assessment provides a specifically nonlinguistic comparison against which to gauge a child's language performance. Play can be used as a context for examining cognitive skills often assessed in more traditional intellectual assessments (Dykeman, 2008; Linder, 1993). It can also be observed to gain insight into particular aspects of the child's conceptual and imaginative abilities. The point of play assessment, and more generally of cognitive assessment at the 18- to 36-month level, is not to decide whether the child has the "prerequisite" cognitive skills for learning language. Language learning is more complicated than that. The main thing we have learned about the connection between language and cognition is that we cannot specify what their relationship is, except perhaps for very small segments of time, and even then there is no clear chicken or egg. The point of these assessments is to sketch a fuller picture of the equipment the child is bringing to the task of learning to talk. Knowing what play abilities the child has helps to decide, not so much the language skills the child is ready to learn, but the activities, materials, and contexts that will be most appropriate to encourage that learning and the conceptual referents on which it might focus. Play also is the most natural context for language learning. Knowing the level of play behavior that the child is able to use can help the clinician structure play sessions that will maximize the child's participation and opportunities for learning.

A variety of methods are available for assessing level of play skills in children at the 18- to 36-month developmental level. Several of these were outlined in Chapter 2. Any of these assessments can serve to identify the child's play skills to determine how they can be put in the service of language acquisition. An additional assessment tool specifically designed for the toddler developmental level is the *Communication and Symbolic Behavior Scales-Developmental Profile* (Wetherby & Prizant, 2003). This procedure analyzes samples of interactive play behavior and allows the clinician to score both symbolic and combinatorial play, in order to provide a general level of symbolic development that is relatively independent of language. It has been shown to be reliable and valid for identifying children with developmental delays in the emerging language period (Wetherby, Allen, Cleary, Kublin, & Goldstein, 2002).

Another method is Carpenter's (1987) *Play Scale*. This scale was designed to assess symbolic behavior in nonverbal children who don't "talk out" their play, so that symbolic skills must be inferred from their interactions with objects. As such, the scale is useful both for nonspeaking toddlers and for older children at the emerging-language stage. To use this scale, a parent is asked to play with the child by engaging in four play scenes with appropriate props: a tea party, a farm, and scenes involving transportation and nurturing. Parents are asked to follow the child's lead in interacting with each set of toys for just 8 minutes. Parents are advised to respond to the child in a natural way, but to let the child play without continually talking or giving directions. Parents are asked not to touch the toys unless invited to by the child and not to give suggestions for play. They are given specific prompts to provide only when the child will not touch or play spontaneously with a set of toys. A detailed description of this assessment can be found in Carpenter (1987). A sample of behaviors examined by this assessment and the ages at which they are mastered by more than 90% of children with normal development appear in Table 7-1.

McCune (1995) also provided a detailed method of analyzing play behavior. Using her system, the child is given a standard set

TABLE 7-1 Play Scale Items

Play Behavior*	Definition	Example	Age
Semi-appropriate toy use	Uses object in appropriate but fleeting way; object need not be correctly oriented.	Touches comb to hair with tines facing up; puts blanket on doll in crib but only covers doll's face.	12 mo
Nesting	Object(s) placed or stuffed into a container; need not be correctly oriented or topic-related.	Crams all toys into crib; tosses all cars into cowboy hat.	15 mo
Multiple play episodes with different actions	Two or more appropriate or semi-appropriate toy uses that are thematically related and involve different actions; object may or may not be the same.	Pushes truck, loads blocks in truck; feeds doll with spoon, gives cup to parent to drink.	18 mo
Multiple play episode with same action	Two or more appropriate or semi-appropriate toy uses that are thematically related; the actions are the same but the objects differ.	Feeds doll with spoon, feeds self with spoon; pushes truck, Jeep.	21 mo
Extended multiple play episode	Three or more appropriate or semi-appropriate toy uses that are thematically related. There must be three different actions; objects may or may not be the same.	Dials telephone, puts telephone to ear and talks, hangs up; takes doll out of truck, puts truck in garage, puts doll on motorcycle and "drives" away.	24 mo

*Play behaviors for which three examples were produced by more than 90% of children at given age in a play session in which children interacted with parent during four play scenes for 8 min each. Play scenes: tea party (dolls, table, chairs, eating and cooking utensils); farm animals; nurture (dolls, crib, toy comb, brush, bottle, telephone, hat); transportation (garage, cars, trucks, boats).

Adapted from Carpenter, R. (1987). Play scale. In L. Olswang, C. Stoel-Gammon, T. Coggins, & R. Carpenter (Eds.), *Assessing prelinguistic and early linguistic behaviors in developmentally young children* (pp. 44-77). Seattle: University of Washington Press.

of toys including a toy telephone, dolls, a toy bed and covers, a toy tub, a tea set, combs and brushes, a toy iron and ironing board, toy cars, toy foods, and similar items. The child is then invited to play with the objects along with a familiar adult. Criteria for analyzing the behaviors observed are ordered hierarchically; they are summarized in Table 7-2. The highest level of play the child exhibits spontaneously can be taken as the child's current level of symbolic behavior. Once this has been established, an emerging level of symbolic play also can be identified by having the clinician model the next level of symbolic play. If the child imitates this model, emergence into the next level of symbolic behavior can be inferred. The types of symbolic behavior that the child can attain in assessments such as these can be used as contexts in which language intervention takes place. In addition, higher levels of play behavior can be modeled by the clinician and parents in informal interactions with the child. These models can help the client evolve toward more advanced modes of symbolic thinking that will, in time, provide even richer contexts for language acquisition.

Casby (2003b) provided guidance for conducting these assessments. He suggests presenting the child with a set of toys that lend themselves to pretend. These include blocks, balls, rattles, and paper and crayons, dolls or stuffed toys, feeding utensils (cup, spoon, etc.), hygiene utensils (brush, washcloth, etc.), nurturing toys (blanket, bottle), and a toy telephone. The clinician can then begin playing out a theme, such as feeding the doll, in parallel play with the child, modeling a range of play behaviors. The highest level of behavior the child demonstrates in response to these models can be scored. Casby also suggests that the child should also be allowed to play alone with the materials for part of the time, in order to look for differences in play when a model is absent.

Assessing Gesture

Use of gestures is an additional aspect of symbolic behavior. Several studies have shown that gestures are highly related to language in early development (Bates & Dick, 2002; Crais,

Watson, & Baranek, 2009; Goldin-Meadow & Butcher, 2003). Goldin-Meadow and Butcher (2003) discuss the fact that young children often rely on gestures to express meanings when they are still very limited in their verbal abilities, and that word-gesture combinations often lead the way to multiword speech. Evans, Alibali, and McNeil (2001) showed that children with language disorders, too, use gestures to express meaning that is beyond their linguistic capacity. Moreover, Goodwyn, Acredolo, and Brown (2000) showed that children whose parents used word-gesture combinations in interactions when they were infants outperformed control groups on language measures when they were toddlers. Both Capone and McGregor (2004) and Crais et al. (2009) showed that, for children with a variety of communication disorders, early use of gestures tends to predict language development. Gesture use, then, may be an important prognostic indicator for children with delayed language. Capone and McGregor (2004) discussed the types of gestures that can be assessed and the general sequence of gestural development (Table 7-3). Crais et al. (2009) showed that typically developing children as young as 9 to 12 months already express a range of communicative intentions through gesture, including protesting, making requests, seeking attention, initiating social games and initiating joint attention.

Two assessment instruments provide information on gesture production. The *MacArthur-Bates Communicative Development Inventory* (Fenson et al., 2007) includes questions for parents on child gesture production. The *Communication and Symbolic Behavior Scales* (Wetherby and Prizant, 2003) also has a scale for observing gestures during a play interaction. Assessment of gestural use also can take place in the context of play assessment (Crais et al., 2009). Notations can be made when gestures appear, using a form like the one in Figure 7-1. Crais et al. (2009) provide guidance on interpreting the assessment of gesture. These are summarized in Table 7-4.

TABLE 7-2 Guidelines for Play Assessment

Approximate Developmental Level	Symbolic Play Level	McCune (1995) and Nicolich (1977) Criteria	Examples
<18 mo	1	Presymbolic scheme: the child shows understanding of conventional object use or meaning by brief recognitory gestures. There is no pretending. Properties of present object are the stimulus. Child appears serious rather than playful.	Picks up a brush, touches it to hair, drops it. Picks up the toy telephone, puts it to ear, sets it aside.
18–24 mo	2	Autosymbolic scheme: the child pretends at self-related activities. Pretending is present. Symbolism is directly involved with the child's body. Child appears playful, seems aware of pretending.	Swishes broom on floor briefly. Pretends to drink from toy teacup. Eats from an empty spoon. Closes eyes, puts hands by cheek, pretending to sleep.
24–36 mo	3	Single-scheme symbolic games: the child extends symbolism beyond own actions by including other agents or objects of actions. Pretending at activities of other people or objects such as dogs, vehicles, etc.	Feeds doll. Brushes doll's hair. Pretends to read a book. Pretends to sweep floor. Moves a block or toy car with appropriate sounds of vehicle.
24–36 mo	4	Combinatorial symbolic games: 4a. Single-scheme combinations: one pretend scheme is related to several actors or pretend receivers of action. 4b. Multischeme combinations: several schemes are related to one another in sequence.	Combs own, then mother's hair. Drinks from toy bottle, then feeds doll from bottle. Puts empty spoon to mother's mouth, then experimenter and self. Holds telephone to ear, dials. Kisses doll, puts it to bed, puts blanket on. Stirs in the pot, feeds doll, washes dish.
24–36 mo	5	Hierarchical pretend: 5a. Planned single-act symbolic games: the child indicates verbally or nonverbally that pretend acts are planned before being executed. 5b. Planned multischeme symbolic acts.	Finds the iron, sets it down, searches for the cloth, tossing aside several objects. When cloth is found, irons it.

TABLE 7-3 Gestures and Gestural Development in the Prelinguistic and Emerging Language Stages

Gesture Type	10–12 Mo	12–13 Mo	15–16 Mo	18–20 Mo
<i>Deictic</i> (showing, giving, pointing, ritualized requests such as reaching)	Deictic gestures emerge; use of pointing predicts first word use		Gestures complement spoken forms; children show preference for either gestural or vocal expression	Increased pointing in combination with spoken words
<i>Symbolic</i> (play schemes, including recognitory gestures: actions carried out on an object to depict the object and its function; e.g., holding a toy telephone to the ear)		Play schemes emerge, recognitory gestures first, then self-directed symbolic play; e.g., "feeding" self from empty spoon	Other-directed play schemes emerge; e.g., pretending to "feed" doll	Transition to play schemes w/out object; e.g., holding hand to ear instead of toy telephone to pretend "talking"
<i>Representational</i> (do not manipulate objects; a form is used to stand for a referent; e.g., flapping arms to represent a bird)		Representational gestures emerge; e.g., puts hand to mouth to indicate wants bite of Mom's cookie	Gestures complement spoken forms; children show preference for either gestural or vocal expression	Multischeme symbolic play emerges; e.g., "stirring" then "feeding" Gesture-plus-spoken word combinations emerge; increase in word use; preference for words over gestures

FIGURE 7-1 Sample form for recording play and gestural behavior.

	10-15 mo. level	15-18 mo. level	18-21 mo. level	21-24 mo. level
Deitic	Show _____ Give _____ Point _____ Ritualized request _____		Deictic gesture accompanies word _____	
Symbolic	Recognitory gesture _____	Self-directed play _____	Other-directed play _____ Play scheme w/o object _____ Sequence of play schemes _____	Planned multischeme play _____
Representational	Representational gestures _____		Representational gestures accompany speech _____	Gesture-plus-word combinations used to express two-word meaning _____

TABLE 7-4 Gestural Behaviors Important in the Identification of Developmental Disorders

Gestural Factor	Consequence
Frequency	Toddlers with a variety of disabilities use fewer gestures than typical peers.
Type	Onset of pointing predicts language development; children with ASD and Down syndrome are frequently late to acquire pointing.
Communicative function	Limited variety of gestures (particularly for the purpose of joint attention and social interaction functions) in toddlers 18–24 months is associated with later diagnosis of autism and other developmental disabilities.
Coordination of gesture with gaze and vocalization	By 15 months, typically developing toddlers combine gestures with gaze and/or vocalization. Lack of this coordination is associated with language delay and/or ASD.
Transition from contact to distal gestures	Failure to acquire gestures to indicate objects at a distance is associated with developmental disorders; it is frequently seen in ASD.
Transition to words	By 16 months, typical toddlers use words and gestures to name objects, by 20 months words predominate as names for objects. Children who persist in using gestures to label objects after 20 months may evidence language delay.

Adapted from Crais, E., Watson, L., & Baranek, G. (2009). Use of gesture development in profiling children's prelinguistic communication skills. *American Journal of Speech-Language Pathology*, 18, 95-108.

Communication Assessment

A variety of scales are commercially available for assessing a range of communicative skills in children younger than 3. These measures can be used to provide a broad picture of communicative functioning and to decide whether, in general, it is commensurate with the child's current functioning in other areas. Many of the general developmental assessments outlined in [Box 7-2](#) provide a scale or subtest of language ability or contain some items that tap language skills. The *Transdisciplinary Play-Based Assessment* (Linder, 1993), for example, provides opportunities for observing social-emotional, cognitive, communicative, and sensorimotor skills in a play context. It is particularly useful for clinicians working within transdisciplinary assessment settings. However, it is often useful to look at language and communication skills more specifically in a child in the emerging language stage who is suspected of a delay in language development. In this way we can avoid confounding the child's nonverbal abilities with any deficits in communication that might exist. This is particularly useful for toddlers suspected of having specific communication deficits rather than more general developmental delays.

Here's one strategy for assessing a child with emerging language:

1. Obtain general developmental level from assessment by a psychologist or developmentalist, using one of the general scales outlined in [Box 7-2](#), or by a transdisciplinary team using *Transdisciplinary Play-Based Assessment (TPBA)*.
2. If developmental level is near to or greater than 18 months, use the developmental level to guide a more in-depth comparison of language and nonlinguistic skills. First administer a play assessment (or use data from the TPBA to evaluate play behavior) as a nonverbal index of cognitive development. This index can be used to decide whether the child with emerging language appears to be at or near the level of symbolic development that would ordinarily accompany symbolic communication.
3. Assess language and communication and compare them to nonverbal abilities. If nonverbal symbolic and communicative abilities are both very low, then intervention may focus on providing play contexts that can elicit early symbolic behaviors while providing simple language input around the emerging levels of play. If, on the other hand, symbolic play is more advanced but communication and language are found to be at

lower levels, more focused language elicitation techniques in appropriate play contexts may be used.

We will talk more about decision-making strategies for planning communicative intervention for this developmental level shortly. For now the important point to be made is that we want to have a relatively independent assessment of nonverbal cognitive or symbolic ability and language or communication. One effective way to meet this goal is to assess play and gesture behavior and to use some additional means of assessing communication level, as well.

There are two approaches to accomplishing the communication portion of this assessment. One is to use a formal assessment instrument. Appendix 7-1 lists instruments available either commercially or in the research literature. Some, such as the *Language Development Survey* (Rescorla, 1989) and the *MacArthur-Bates Communicative Development Inventories* (Fenson et al., 2007), use a parent-report format. Others use direct assessment or a combination of direct observation and parent report. The *Communication and Symbolic Behavior Scales—Developmental Profile* (Wetherby & Prizant, 2003) provides an example of one form of direct assessment, and also has parent-report components. The instrument can be used with children who function at the emerging language stage but are as old as 6 years in chronological age. It also has been demonstrated to be valid with children from mainstream (Eadie et al., 2010) as well as culturally different backgrounds (Roberts, Medley, Swartzfager, & Neebe, 1997). Some additional assessment procedures appropriate for this developmental level can be found in *Preschool Functional Communication Inventory* (Olswang, 1996), *Interdisciplinary Clinical Assessment of Young Children With Developmental Disabilities* (Guralnick, 2000), *Alternative Approaches to Assessing Young Children* (Losardo & Notari-Syverson, 2001), and the *Assessment, Evaluation, and Programming System for Infants and Children* (Bricker, Capt, & Pretti-Frontczak, 2002). All these sources include dynamic, criterion-referenced procedures that use developmentally appropriate approaches for evaluating young children.

A second method of assessing communication involves using informal methods to examine communicative functioning in several domains independently. This strategy, advocated by Crais et al. (2009) and Paul (1991b), has the advantage of integrating assessment and intervention activities and allowing more detailed intervention planning. This is possible because, instead of a general level of communication, the procedure allows several areas of communicative behavior to be examined separately and a level of development established in each. In this way, a profile of communication and related abilities can be derived, and specific intervention targets in nonverbal communication, expressive language, receptive language, and phonology can be readily identified.

Paul (1991b) outlined informal procedures for profiling early communicative skills. Many areas assessed in this procedure are very similar to those examined in the *Communication and Symbolic Behavior Scales* (Wetherby & Prizant, 2003). This procedure is described in some detail here, not as an endorsement, but to give the student clinician a detailed idea of what is involved in informal assessment of the various areas of communication at this developmental level.

ASSESSING COMMUNICATIVE INTENTION

Even before they begin to talk, children with emerging language attempt to communicate with those around them. This communication can take several forms. It can be verbal, through the use of

single words or combinations of words, or it can be nonverbal, through the use of a variety of gestures and sounds. Children can get their messages across by pointing, reaching, whining, babbling, or vocalizing a variety of protowords that don't sound like adult targets but do have speech-like components. Many of these nonverbal forms can be recognized by adults as attempts to communicate. Very often an adult familiar with the child with emerging language can discern the child's intention in these nonverbal forms.

There are several ways in which communication typically changes over the course of the second and third years of life. One way is that it becomes more verbal, with nonverbal means of communication gradually giving way to more conventional verbal forms. Another way is that attempts increase in frequency, with rates of communication more than doubling over the 18- to 24-month period. A third way is that the range of intentions the child is trying to express broadens. The result of all these changes is that by the third birthday, the normally developing toddler is more like an adult speaker than like his or her 1-year-old counterpart. Paul and Shiffer (1991), Pharr, Ratner, and Rescorla (2000), and Rescorla and Mirren (1998) showed that late-talking toddlers generally show lower rates of communication, vocalization, initiation, and joint attention, even nonverbally, than their typical peers.

When toddlers are referred for evaluation, it is usually because they have failed to begin talking or are talking very little. One of the things we need to learn about such toddlers, or about an older child with emerging language, is whether this failure to speak is accompanied by a more pervasive deficit in the ability to communicate generally or whether it is restricted to the oral symbolic modality of speech. That is, we need to know whether and how the child is sending messages nonverbally. Children with little speech who attempt to communicate with those around them by other means have a potentially strong foundation that can support the growth of functional language. On the other hand, children with both sparse speech and little or no nonverbal communication have less motivation to acquire symbolic forms, since they are not so actively engaged in attempting to send messages to others. These children may need to learn the purpose of communication in order to lay the communicative grounding on which language can be built.

To assess communicative function in this age range, we need to observe the child playing with some interesting toys and a familiar adult. Casby (2003b) and Westby (1998b) emphasize the importance of providing low-structure interactions in which toys are accessible and the adult follows the child's lead. This encourages the child to call the adult's attention to himself and his actions and prevents an over-representation of request acts. The same toys used in the play assessment can be used here. In fact, if the play assessment is videorecorded, it can be viewed again as a sample of communicative behavior. Because the rate of communication is generally quite low at this developmental level, though, it also is possible to observe communicative behavior without recording but by simply watching a client interact with a parent. After some practice, most clinicians can learn to score communicative behavior in real time (Coggins & Carpenter, 1981), so long as this is the only behavior they are trying to observe. If play assessment also is to be done from a real-time observation, it will have to be done in a separate session, even if the same materials and participants are involved.

Three aspects of communication can be examined as part of this assessment: the range of communicative functions expressed, the frequency of communication, and the means by which the child

attempts to convey his or her messages. Let's look a little more closely at each of these areas.

Range of Communicative Functions

There are a variety of schemes for summarizing the communicative functions typically seen in normally developing toddlers (see Chapman, 1981; Paul & Shiffer, 1991; and Wetherby et al., 1988, for review). Perhaps the most accessible system, though, is the one outlined by Bates (1976) and elaborated by Coggins and Carpenter (1981). Bates divided early communication into two basic functions: *proto-imperatives* and *proto-declaratives*. Proto-imperatives are used to get an adult to do or not do something. They include the following:

Requests for objects: Solicitation of an item, usually out of reach, in which the child persists with the request until he or she gets a satisfactory response.

Requests for action: Solicitation of the initiation of routine games or attempts to get a movable object to begin movement or reinstate movement that has stopped.

Rejections or protests: The expression of disapproval of a speaker's utterance or action.

Proto-declaratives are preverbal attempts to get an adult to focus on an object or event by such acts as showing off or showing or pointing out objects, pictures, and so on, for the purpose of establishing social interaction or joint attention. By far the most frequent proto-declarative function seen in normally developing toddlers (Paul & Shiffer, 1991) is the *comment*, which is used to point out objects or actions for the purpose of establishing joint attention. Comments are very important in the development of mature language because they establish the framework for the topic-comment structure of adult conversation. Social-interactive intentions, such as showing off or calling attention to self, can also be included in this category. Both proto-imperative and proto-declarative intentions appear in normally developing toddlers between 8 and 18 months of age.

Beyond these earliest appearing intentions, several new communicative functions appear for the first time at about 18 to 24 months in normally developing children. These new intentions are evidence of more advanced levels of communicative behavior. They have what Chapman (1981, 2000) called *discourse functions*;

that is, they refer to previous speech acts rather than objects or events in the world. They indicate that the child has now incorporated some of the basic rules of conversation into a communicative repertoire, such as the conversational obligation to respond to speech. These discourse functions include the following:

Requests for information: Using language to learn about the world. At the earliest stages, the requesting information function can take the form of requests for the names of things ("Whazzat?"). Later, they may include a *wh-* word, a rising intonation contour, or both.

Acknowledgments: Providing notice that the previous utterance was received. In young children this is often accomplished verbally by imitating part of the previous utterance or nonverbally by mimicking the interlocutor's intonation pattern. Head nods also can communicate this intention.

Answers: Responding to a request for information with a semantically appropriate remark.

These more advanced intentions, then, are evidence of a higher level of communicative function than the use of the earlier set alone. All seven of the communicative functions we've discussed are listed on the Communication Intention Worksheet in Figure 7-2.

When looking at the range of intentions expressed, we try to determine, first, whether the full range of the early developing intentions is being used. This is because various kinds of disabilities show different profiles of expression of communicative intentions. Mundy and Burnette (2005) and Mundy and Crawson (1997) report, for example, that children with autism are likely to produce proto-imperative functions but less likely to produce proto-declaratives. Children with Down syndrome, on the other hand, show more proto-declarative intentions but have deficits in proto-imperatives. Similarly, Paul and Shiffer (1991) reported that toddlers with slow language development produced significantly fewer proto-declarative comments, even nonverbally, than their normally speaking peers. So failure to produce the full range of early intentions, particularly comments, may be an important indicator of diagnostic category and prognosis in children with delayed language development.

If the full range of early intentions is observed, we then want to determine whether any of the higher level intentions are being expressed. If so, the client would clearly be ready to learn words for mapping these intentions. If not, conventional words for the

early intentions expressed could be targeted. In addition, the clinician could provide simple one-word models of the more advanced intentions. The SLP might, for example, acknowledge client utterances consistently, saying “Yes!” before going on to comment on the child’s remark. Clinicians also can model seeking information by stating simple questions for the client, then answering them (that is, when looking at the client’s shirt, the SLP can say, “What color? Green!”).

Frequency of Expression of Intentions

We’ve talked about how the frequency of communication changes over the age range in which language normally emerges. We expect 18-month-olds to produce about two instances of intentional communication per minute, whereas we generally see more than five per minute in 24-month-olds (Chapman, 2000). If a prelinguistic client over 18 months of age produces fewer than 10 total communicative acts within a 15-minute observation (and if the parent affirms that the behavior during the observation was more or less typical of the child), this rate would be considered significantly low. In addition, Yoder, Warren, and McCathren (1998) reported that children with mild to moderate intellectual disability in the prelinguistic period were unlikely to develop functional speech if they produced fewer than one proto-declarative communication act every five minutes. This suggests that if a nonspeaking client produces fewer than three proto-declarative acts within a 15-minute observation period, there is a risk for development of functional speech. In both these cases, intervention would focus not only on eliciting single-word productions, but also on increasing the frequency of nonverbal communication, particularly proto-declaratives. Communication temptations, such as those outlined by Prizant and Wetherby (1989), may be useful for this purpose.

Forms of Communication

As children progress through the emerging language period, they increase the sophistication of the forms of communication they use. Chapman (1981, 2000) summarized the progression this way:

1. Gestural means of communication are predominant at approximately 8 to 12 months of age.
2. Gestures are combined with word-like vocalizations containing consonants at 12 to 18 months.
3. Conventional words or word combinations are used with increasing frequency to express a range of intentions at 18 to 24 months.

So another aspect of the child’s communication that we would note is the form used. Purely gestural forms would be considered less advanced than vocalizations, which are in turn less mature than conventional words. These stages of communicative form are included in Figure 7-2.

Yoder, Warren, and McCathren (1998) demonstrated that prelinguistic children who produced fewer than one vocal communication act every four minutes were significantly less likely to develop functional speech 1 year later. If fewer than four vocal communications are produced in a 15-minute communication interaction, then an attempt ought to be made to elicit vocalizations for functions the child is already expressing with gaze and gestures. We may need to help children understand that we must do something relatively specific with our mouths to communicate effectively, and this effort may need to precede elicitation of particular words. If, on the other hand, four or more functions are

expressed with vocalizations in a 15-minute sample, words should be taught first in the context of those functions. Later the same words can be taught to express other functions currently expressed with gestures alone.

Using a Communication Intention Worksheet

A worksheet such as the one in Figure 7-2 can be used to summarize the child’s performance during an assessment of intentional communication. Column heads list the form of the communicative act: gesture, vocalization, or conventional word. For the earliest-appearing intentions or functions (proto-imperatives and proto-declaratives), the form of the communication determines its level. For any of these early appearing functions, a gestural form is taken as evidence of performance comparable to that of a normal 8- to 12-month-old. A gesture plus a speech-like vocalization (“dada”) or nonconventional word-like vocalization alone is considered evidence of 12- to 18-month-level performance. An intelligible word or word approximation is assigned to an 18- to 24-month level. For the later-developing intentions—such as requesting information, acknowledging, and answering—the form, whether gesture, vocalization, or word, is noted in much the same way as it is for the earlier set. However, here the form does not determine communicative level. Form is merely noted for intervention planning. All the later-developing intentions are considered evidence of 18- to 24-month communication performance.

Clinicians who devote time to learning the coding system for communicative intents can score a 15-minute interaction involving a nonverbal or minimally verbal child, using Figure 7-2, during short interactions without resorting to recording. The most common mistakes made in using this coding system involve being too generous in attributing communicative intent to the child (that is, beginning clinicians are likely to score any action of the child’s as some form of communication). To qualify as communicative act, though, a child’s behavior must satisfy the following criteria:

1. It must be directed, primarily by means of gaze, to the adult.
The child must look at, refer to, or address the adult directly in some way as part of the act.
2. It must have the effect, or at least the obviously intended effect, of influencing the adult’s behavior, focus of attention, or state of knowledge. The child must be obviously trying to get a message across to someone.
3. The child must be persistent in the attempt to convey a message if the adult fails to respond or responds in a way the child had not intended.

A clinician can become skillful in this kind of observation by coding interactions with another clinician, learning to recognize the communicative acts as a team, then coding independently until their reliability reaches a 90% level.

This form of communication assessment is not based on standardized, quantitative procedures. So it is not crucial to score every single communicative act within an observation period. Instead, a clinician should attempt to note and score the general—not the precise—frequency and function of communication by recording as many acts as can be coded with a reasonable degree of certainty. Note can be taken of the diversity both of functions expressed and of the forms used to express them. Such assessment data have the potential to yield an index of the three dimensions of communicative behavior we have been discussing: (1) *frequency of communication*, (2) *diversity of functions* expressed, and (3) *diversity of*

forms used to express the functions. This index can serve as a guide to planning an intervention program that helps the child to expand the frequency and range of intentions expressed and increase the maturity of the means of expression.

In addition to assessing the child's communication, there also are instruments for assessing parent communication, which we looked at in Chapter 6. Another example is *The Infant-Toddler Family Assessment Instrument* (Apfel & Provence, 2001). As we discussed before, though, it is very important to avoid any appearance of blaming the parent for the child's communication problem. Research on language-disordered children in general (Leonard, 1989) and on toddlers with slow expressive language development in particular (Paul & Elwood, 1991) indicates that parental input is generally well-matched to the child's language level, although there are some subtle differences in the input to late talkers (Vigil, Hodges, & Klee, 2005). This is not to say that there won't be some parents who are poor communicators. But in general, the great majority of parents are doing the best they can to get through to an often hard-to-reach child. They don't need to be made to feel that they are at fault if their child is not developing normally. Rather than subjecting parents to an intimidating assessment of their own communication skills, we would be better off just to ask them what makes communicating with their child hard for them. We can then offer suggestions to address the concerns they raise. These suggestions will probably be the same ones we would offer in any case: following the child's lead, modeling talking about ongoing experiences with self-talk, expanding on what the child says or indicates interest in, limiting initiating new topics, giving the child time to respond, and using other indirect language stimulation techniques and communication temptations (Girolametto, Weitzman, Wiigs, & Pearce, 1999; Ingersoll & Dvortczak, 2010; Vigil et al., 2005). Isn't it better to offer these suggestions in a spirit of helping the parent with needs he or she identifies than as a correction of the parents' mistaken attempts?

We also need to be sensitive to cultural differences in communication styles. Parents from all cultures do not talk to toddlers the way middle-class contemporary American parents do (Garrett, 2002; Richman, Miller, & LeVine, 2010; Rodriques & Olswang, 2003; Westby, 1998b). We in mainstream America tend to use a very contingent form of interaction, making our remarks depend on what the child contributes. However, many other cultures use a more routine style: providing, in a variety of settings, repetitive, predictable language that is initiated by the parent rather than the child. Some cultures use child-rearing patterns that involve encouraging children to listen and observe interactions, rather than speaking themselves. And in many cultures young children spend most of their time with multiple caregivers, including older siblings, rather than with their own mothers. Toddlers in all these cultures learn to talk at about the same rate as toddlers in our own. Our way is one way that works to teach language to children, but there are other ways. If we see parents using these more routine styles, we need to be aware that these styles are not "wrong." They may, in fact, be more "right" for a child who will eventually function within that cultural group than the styles we prefer.

There are some clues, though, that parent interactional style has an effect on how children respond to intervention. Brady et al. (2004) and Yoder and Warren (1998) showed that prelinguistic children with more responsive mothers were more likely to increase the frequency and maturity of their communication in structured intervention. Children with less responsive mothers did better with a small group intervention program that incorporated a

Assessing expression of communication intentions.

more child-centered, facilitative play method. These data suggest that rather than judging parental style as "good" or "bad," we may want to understand it in order to help decide what intervention approach will be most effective for a particular child from a particular family.

To summarize the communicative intention assessment, then, we want to evaluate communicative behavior independent of conventional language use. Looking at the frequency of communicative behavior and the diversity of forms and functions the child has available helps us decide what the client is most ready to learn. If little communicative behavior is present, we need to get clients to see what communication is for and to find ways of getting messages across to others. We can then help them find more conventional means for expressing the intentions they are developing. Parents must see us as allies in this enterprise, since they will be doing much of the communication with the child. It is crucial that we respect their concerns and individual styles of interacting, then try to choose an intervention that complements their style.

ASSESSING COMPREHENSION

Understanding of words in the second year of life is predictive of both expressive and receptive language development as much as 2.5 years later (Bernhardt, Kemp, & Werker, 2007). But as Chapman (1978) long ago pointed out, parents often claim that children as young as 12 months "understand everything" said to them. Still, researchers have found receptive language skills to be quite limited at this age. Normally developing children accomplish this "deception" by the use of a series of strategies for comprehending linguistic input. These strategies change with development to incorporate new linguistic knowledge as it is acquired and to integrate it with knowledge of the way things usually happen. The use of comprehension strategies not only enables the child to "look good" in receptive language activities, but also provides children with stepping-stones to the next level of development by allowing them to participate successfully in interactions and get feedback on their performance. For example, a mother playing with a 10-month-old girl might point to a ball on the floor while saying to her, "Get the ball!" The child would not have to comprehend a single word to comply with the instruction. All she would have to do is to

follow the point gesture and then act in the most customary way on the object noticed. A strategy like “Look at what mother looks at; then do something about it,” would allow her to appear to interact successfully without really knowing the meaning of the words. The child would at the same time, though, be learning to make a connection between the word *ball* and the round thing. Table 7-5 summarizes the strategies identified by Chapman (1978), Edmonston and Thane (1992), and Paul (2000a) that are used in the 1- to 3-year age range.

When evaluating very young children with delayed language, then, we need to be careful about relying totally on parental impressions of children’s receptive skills. Like normally developing children, children with delayed linguistic development may use strategies that make them appear to understand language when in fact their comprehension is based on attention paid to nonlinguistic behaviors and cues, such as gaze, gestures, and situations, or event probabilities (Coggins, 1998; Miller & Paul, 1995; Paul, 2000a). It is important, then, to assess the status of receptive language skills in any child at risk for delayed language development.

Very few standardized tests of receptive language for children younger than 3 years are available. Many of those that are, such as the *Peabody Picture Vocabulary Test—Revised (PPVT-IV)* (Dunn & Dunn, 2006) or *Communication and Symbolic Behavior Scales-DP* (Wetherby & Prizant, 2003), assess only single-word vocabulary. Parent checklists designed to assess receptive vocabulary have been shown to be less reliable than those assessing expressive skills at the emerging language level (Dale, 1991; Thal, O’Hanlon, Clemmons, & Fralin, 1999). General scales, such as the *Receptive-Expressive Emergent Language Scale, 3rd Edition* (Bzoch, League, & Brown, 2003), the *Sequenced Inventory of Communicative Development* (Hedrick, Prather, & Tobin, 1995), and the others listed in Appendix 7-1, look at a range of responses to both verbal and nonverbal auditory stimuli. While these general measures can be quite useful for assessing listening skills, more specific information about how children process word combinations and sentences is helpful for deciding what a child is able to discern from the language in the environment. Miller and Paul (1995) provided a broad range of comprehension assessment activities for this developmental level. We’ll outline a sampling of them here.

The major questions to be answered about the comprehension skills of children in the emerging language stage first involve

whether words are understood at all without the support of nonlinguistic cues. If so, we will want to know whether words within a sentence can be processed and semantic relations understood. These questions can best be answered observationally, not only because there are few standardized tests for children at this level, but also because, as Coggins (1998) and Paul (2000a) pointed out, comprehension in very young children is highly context-dependent. As a result, the ability to manipulate context, disallowed in standardized tests, is an important aspect of the assessment. Also, the vocabularies of these children may be somewhat idiosyncratic. The words they understand may not be those routinely tested on standardized instruments. They may, instead, be words for the family pet, for a particular toy, for a favorite game, and so on. It is often useful, when planning an assessment session, to interview parents briefly on the telephone about their child’s comprehension skills. They can then be asked to bring to the evaluation several items whose names the child might know.

In the first phase of comprehension assessment, the clinician determines whether the child understands any single words without the support of nonlinguistic cues. A collection of six to eight objects (the names of which the parents indicated the child may know) is placed before the child. Single words are then presented in a simple sentence frame (“Give me . . .”). The clinician must be careful not to look at the item being named, point toward it, or name an item the child already is handling or reaching toward. Since only the word for the object is being tested in this procedure, a gesture, such as holding out the hand, can be used to indicate “Give me . . .” Several other words, such as person names (e.g., Mommy, child’s name) and nouns for body parts and locations (e.g., table, chair, floor, door), can be tested using a “Where’s (object)?” sentence frame. These instructions can be modeled by first asking the parent, “Where’s the table?” and having the parent demonstrate answering the question by touching or pointing to the named object.

If the child can identify several nouns in this way, verbs can be tested next. Words for actions that the parent indicated the child is likely to know, such as *kiss*, *hug*, *bite*, *push*, *pat*, *throw*, and *hit*, can be tested by offering the child an object (since only the verb is being tested here) and saying “Hit it. Throw it. Pat it.” and so on. It is necessary in both the noun and verb assessments to have the child demonstrate comprehension of each word two to three times

TABLE 7-5 Summary of Comprehension Abilities in Children Up to 3 Years Old

Age	Comprehension Ability	Comprehension Strategy
8–12 mo	Understands a few single words in routine contexts	1. Look at same objects as mother 2. Act on objects noticed 3. Imitate ongoing action
12–18 mo	Understands single words outside of routine, but still requires some contextual support	1. Attend to object mentioned 2. Give evidence of notice 3. Do what you usually do
18–24 mo	Understands words for absent objects, some two-term combinations	1. Locate objects mentioned, give evidence of notice 2. Put objects in containers, on surfaces 3. Act on objects in the way mentioned (child as agent)
24–36 mo	Comprehends three-term sentences, but context or past experience determines meaning; little understanding of word order	1. Probable location, probable event 2. Supply missing information

Adapted from Chapman, R. (1978). Comprehension strategies in children. In J.F. Kavanaugh & W. Strange (Eds.), *Speech and language in the laboratory, school, and clinic* (pp. 308-327). Cambridge, MA: MIT Press; Edmonston, N., & Thane, N. (1992). Children’s use of comprehension strategies in response to relational words: Implications for assessment. *American Journal of Speech-Language Pathology*, 1, 30-35.

at random intervals during the initial phase of the comprehension assessment. Comprehension of single words without the support of nonlinguistic cues is taken to indicate performance expected at the 12- to 18-month level in normally developing children (Chapman, 1978).

If the child fails to show reliable signs of any lexical comprehension, an attempt can be made to step back and see whether the child makes use of 8- to 12-month-level comprehension strategies outlined in Table 7-5. After the initial phase of the assessment is completed, the same words can be tested again, but this time paired with gestural cues. If performance is better with the addition of these nonverbal cues, the child can be said to be using 8- to 12-month strategies. The worksheet seen in Figure 7-3 can be used to record these data.

If the child demonstrates linguistic comprehension of three to five nouns and three to five verbs at the 12- to 18-month level, testing for 18- to 24-month-level comprehension performance can proceed, as indicated in Figure 7-3. Here the primary goal is to assess understanding of two-word instructions. One such instruction is the *action-object* semantic relation. Because children functioning at 12- to 18-month levels of comprehension use a “Do what you usually do” strategy to respond to such instructions, it is necessary to present *unusual* two-term combinations to assess whether an individual child is responding to the word combinations themselves. Combinations should be generated from the words on which the child succeeded in the first part of the assessment. Using a worksheet like Figure 7-3, we can list words comprehended during the first phase of the assessment in the 12- to 18-month section. In the 18- to 24-month section, the *action (verb)-object (noun)* combinations of these words that we use to test understanding of word combinations can be recorded. Unexpected combinations would include instructions such as “Kiss the apple,” “Hug the shoe,” and “Push the baby.” Each action-object combination should be tested several times, as in the individual noun and verb assessments.

If a child fails to respond correctly to a majority of the two-term combinations presented, then probable combinations can be presented to assess whether the more basic 12- to 18-month level

strategy “Do what you usually do” is operative. Clients can be asked to “Bite the apple” or “Push the car.” If they respond correctly to these instructions but not to the unusual ones, a “Do what you usually do” strategy can account for this performance. (Some children may demonstrate a reliance on this strategy when responding to the unusual combinations in the assessment [that is, when told to “Kiss the apple,” they may bite it, or when told to “Hug the car,” they may push it]).

If the child succeeds on a majority of the 18- to 24-month items, demonstrating linguistically-based comprehension of two-term relations, we can move on to the next phase of the comprehension assessment, in which we try to determine the presence of appropriate behaviors at the 24- to 36-month level. Typical children at this level are able to process *agent-action-object* instructions, but they still rely on a “probable event strategy” for deciding which noun represents the agent and object of action. When presented with a sentence such as “The mommy feeds the baby,” children in the 24- to 36-month period typically perform successfully on object manipulation tasks. But if asked to act out the sentence, “The baby feeds the mommy,” they are likely to interpret it in the more probable direction (mommy feeds baby). To test for basic 2- to 3-year-level comprehension skills, then, a series of probable agent-action-object sentences should be presented, first using the same vocabulary items that were used in the earlier phases of the assessment. Children who get this far in the assessment process generally have larger vocabularies. More nouns (such as *girl, boy, baby, dog*) and verbs (such as *lick, pull, chase*) can be pretested in the same manner as the earlier single words. These words can then be used in constructing probable three-term combinations to be acted out with toys. If children use a “child-as-agent” strategy by performing the requested actions on the named object themselves, we can interpret this behavior as evidence of an 18- to 24-month-level comprehension strategy.

Because these procedures are not standardized, there are no hard and fast criteria for deciding when a child “passes” or “fails” a particular level. If a child is performing correctly on a majority of items at one level, credit for that developmental level of comprehension can be given, at least provisionally, even if the child

Age	Comprehension activity	Linguistic stimuli	No. of trials	Strategy observed from previous level
8-12 mos	Routine games without gestural cues			
12-18 mos	Single words			Look at what examiner looks at; act on objects noticed; imitate ongoing action
18-24 mos	Two-term instructions			Attend to object mentioned; give evidence of notice; do what you usually do
24-36 mos	Three-term instructions: probable			Locate objects mentioned and give evidence of notice; child-as-agent

FIGURE 7-3 Informal comprehension assessment worksheet.

uses some lower-level strategies. If a client is getting the majority of items wrong, we must then ask whether the child is using a comprehension strategy appropriate to the previous developmental level, which is listed in the last column of the worksheet in Figure 7-3. If this is the case, then the previous level of strategy used ought to be attributed to the child. For example, a client may be able to act out unusual two-word combinations, such as “Bite the fish.” When asked to act out three-term combinations such as “Make the horse bite the cow” (24- to 36-month level), though, the child may bite the cow himself or herself. If this happens, failure on the 24- to 36-month-level items is noted on the worksheet. In addition, the “child-as-agent” strategy is circled in the last column of the worksheet at the 24- to 36-month level. This indicates that, although the child is not functioning at a 24- to 36-month stage of comprehension, he or she is using appropriate strategies that would be expected to lead to this level in time. If the child fails the majority of items and does not use strategies from the previous level, comprehension is then ascribed to the highest level at which items were passed.

Children who succeed at the 24- to 36-month level of nonstandardized comprehension assessment can next be tested using formal comprehension measures such as the *PPVT-IV* (Dunn & Dunn, 2006), the *Test of Auditory Comprehension of Language—3* (Carrow-Woolfolk, 1999a), the *Miller-Yoder Test of Grammatical Comprehension* (Miller & Yoder, 1983), *Receptive One-Word Picture Vocabulary Test* (Brownell, 2000), or the *Token Test for Children* (DiSimoni, 1978) to name a few.

If comprehension level is on par with communicative intention level, as assessed by the methods in the previous section, a nonspeaking child can be said to have a relatively isolated language production deficit. If, on the other hand, comprehension skills lag behind communicative intentions, a more pervasive language disorder is present. Longitudinal studies of children with language disorders (Paul, Cohen, & Caparulo, 1983) and toddlers with slow language development (Desmarais, Sylvestre, Meyer, Bairati, & Rouleau, 2010; Olswang, Rodriguez, & Timler, 1998; Yoder & Warren, 1998) suggest that those with poorer comprehension skills have poorer outcomes. Comprehension skills in children with little or no speech, then, may be indicators of prognosis. Analysis of these skills can contribute to the decision as to whether to initiate intervention or continue to monitor language development. Children who have poor comprehension skills but make use of developmentally appropriate strategies may have a better outlook for acquiring receptive skills than children who not only do not comprehend, but also do not make systematic attempts to respond to language. Thal and Flores (2001), for example, showed that the use of comprehension strategies in late talkers, who generally go on to show more or less normal oral language development, was similar to that of younger typical children. Again, information about strategy use in children with receptive problems will help in planning an intervention program.

For children with little or no speech who also have receptive deficits, it is important to build a strong input component into the intervention plan. Focused language stimulation, verbal script activities, and child-centered approaches such as indirect language stimulation, are especially important adjuncts to eliciting expressive language for these clients. Those with limited use of strategies and limited comprehension need additional practice in observing how language maps onto objects and events. Facilitative play and modeling of play behaviors—using both conventional and

symbolic uses of objects—along with simple descriptive language should be added to these clients’ programs.

ASSESSING PRODUCTIVE LANGUAGE

Assessing Speech-Motor Development

One piece of information we would like to have about a client who is not talking concerns speech-motor development. It would be very useful to know whether slow speech development is related to deficits or delays in motor speech abilities. This information is particularly hard to get from children at the 18- to 36-month developmental level, because so much of the speech-motor assessment requires imitation, which children at this developmental level may be unwilling to do. We talked in Chapter 2 about some hints for doing the speech-motor assessment for very young children, such as pretending to make clown or fish faces together, letting the child examine your intraoral cavity with a flashlight first then letting you take a turn, pretending to look for strange creatures in the mouth, and so on. Even the most creative clinician may fail to get the cooperation of a 2-year-old in this phase of the assessment, though. When the child is completely unwilling to imitate oral gestures or let the clinician examine intraoral structures, all we can do is get to know the child better in the course of the intervention program and try again later.

In this case, it is especially important to refrain from jumping to conclusions about relations between speech-motor behavior and speech development. Although Nip, Green, & Marx (2010) showed that there are relationships between language and speech-motor development in the early years, Dodd & McIntosh (2010) reported that motor development was not the strongest predictor of phonological skills in 2-year-olds. In a 2-year-old who is not talking, there is just not enough information available to determine whether speech-motor deficits or childhood apraxia of speech (CAS) contribute to the speech delay. Diagnostic criteria for CAS, as we saw in Chapter 4, include inconsistent speech errors, reversing sounds in words, more errors as utterances become more complex, and errors in stress production (Betz & Stoel-Gammon, 2005; Forrest, 2003; Shriberg et al., 2003). Toddlers who do not talk simply do not produce enough speech to judge whether these symptoms are present, and their imitation skills are too immature to accurately assess oral motor imitation. The best approach to use for a child who is suspected of CAS at this level is to provide the kinds of focused, developmentally appropriate speech and language intervention that we would use for any nonspeaking toddler (e.g., Davis & Velleman, 2000; DeThorne, Johnson, Walder, & Mahurin-Smith, 2009), and monitor progress. Children who show substantial growth in speech production by age 3 probably did not have true CAS. If the kinds of symptoms outlined above begin to appear as the child begins to produce more speech, more focused CAS assessment and intervention methods can be considered.

One aspect of speech-motor development we can accomplish in children in this age range, though, is the feeding assessment. All the instruments and procedures suggested for feeding assessment of infants in Chapter 6 are relevant for children with emerging language, too. The feeding assessment can be used to look for muscular weakness, paralysis, or dysarthric-like conditions that might interfere with speech development. Feeding assessment, though, does not rule out other types of neuromotor disorders that affect only voluntary functions. For these, a more specific speech-motor assessment is needed. Again, we may not be able to be as

thorough as we would like in accomplishing a speech-motor assessment of a child at this level. When we cannot, the best approach is to gather as much information about present and early feeding skills and early babbling behavior as we can. The vocal development assessment in Figure 6-1, or that presented by Nathani, Ertner, and Stark (2006) can be very helpful in the evaluation of prespeech vocal behavior. If feeding and babbling history appear normal, then neuromotor involvement is probably not the primary cause of the slow speech development. If feeding and babbling skills do appear to be problematic, some motor involvement may be implicated. In this case, we would want to try especially hard to do a more thorough speech-motor assessment as we get to know clients better and win their trust and cooperation. But again, we really cannot assess the degree of speech-motor involvement until the child produces enough speech to manifest the characteristic symptoms of CAS. For many late-talking children, this may not be until 3 or 4 years of age, and, in our opinion, no diagnosis of CAS should be made before this point. Nothing is lost in simply providing traditional speech and language intervention to the toddler with limited speech. These techniques will help to develop the conceptual and symbolic foundation for language that will then be in place when the child is developmentally ready for more focused speech therapy to begin.

Collecting a Speech Sample

Children with emerging language being assessed for communication disorder probably don't talk much, so collecting a speech sample may seem an unimportant part of the evaluation. Trying to collect a free speech sample in the clinic setting may, in fact, not be very successful. However, we would like to get some idea of what words and sounds the child is producing. There are two ways we can gather these data: from a sample audiorecorded in the home and from a parent diary.

Perhaps the simplest way to collect a vocalization sample is to send a good audio recording device home with a family and ask them to turn it on during several periods in which the child usually produces a lot of sounds. Playtime with a sibling or during dressing, feeding, or bath time (remind parents to be sure to keep the recorder away from the water!) are often such times. This method allows us to hear the child's vocalization in natural settings and will probably paint a more valid picture of productive skills than trying to elicit words in an unfamiliar environment. Problems can arise, though, if there is too much background noise or if parents

forget to make the recording or return the recorder. Providing a self-addressed stamped mailer or, if possible, going to the home to make the recording may increase the chances of getting it back. As smart phone video capability increases, parents may be able to record several minutes of their children's vocalizations on these several times to send on to the clinician.

Another way to collect information about the child's spontaneous vocalization is to ask parents to keep a diary of the child's productions, again during times when the child normally vocalizes. Miller (1981) provided guidelines for collecting a parent diary. He suggested asking parents to record everything their child produces during several 10- to 15-minute intervals over the course of 1 week. A form such as the one in Figure 7-4 is provided to the parent. Miller suggested that the parents keep a form and pencil with them during several activities when the child usually produces a lot of sounds. Then they simply record as much as they can of both what the child means and how it actually sounds. Miller's method asks parents to note whether the vocalization was an imitation, if it was directed to a particular person, and what was going on when the child said it. This kind of record also can be very helpful in determining the words, sounds, and communicative skills the child is showing. However, it does require a fairly dedicated parent. Clinicians will have to use judgment to decide which families can keep an accurate record. When this task seems to be too much to ask of a family, sending home an audio recording device or getting cell phone video may be a better alternative.

Once a speech or vocalization sample has been collected, we want to examine several aspects of the child's production. These include phonological skills—the sounds and syllable types the child produces—as well as the frequency and types of conventional words the child uses and how the child combines words. Let's look at each of these areas.

Assessing Phonological Skills

Stoel-Gammon (1998, 2002) and Williams and Elbert (2003) talked about the close relationship between the development of words and sounds in very young children. Although it is conceivable that a child could have a rich phonological repertoire in babbling but to fail to use it in meaningful words, this scenario is not usually what we see. Typically, children with small expressive vocabularies also show small phonetic inventories of consonants and a restricted number of syllable shapes in both meaningful speech and in nonverbal vocalizations (Mirak & Rescorla, 1998;

Child's name _____				
Age _____				
Date _____				
Activity observed _____				
<u>Word(s) child meant</u>	<u>How it sounded</u>	<u>Imitated?</u>	<u>Spoken to?</u>	<u>What was happening?</u>
<i>baby</i>	baba	no	Mom	reached for doll
<i>blanket</i>	baki	no	Mom	Mom took blanket from dryer
<i>cookie</i>	googi	no	Mom	reached for cookie jar
<i>cookie</i>	googi	yes	Dad	He asked if she wanted a cookie
<i>no night-night</i>	no ni	no	Mom	bedtime

FIGURE 7-4 Sample parent diary form. (Adapted from Miller, J. [1981]. *Assessing language production in children: Experimental procedures*. Needham Heights, MA: Allyn and Bacon.)

Paul & Jennings, 1992; Rescorla & Ratner, 1996; Williams & Elbert, 2003). Children with autism spectrum disorders may be one exception to this rule (Paul et al., 2006). Generally, the development of words and sounds seems to be very closely linked in both normal and delayed language development (Fletcher et al. 2004). Furthermore, the development of consonants specifically is closely related to the development of words. Whitehurst et al. (1991) have shown that there is a strong correlation between the amount of vocalization containing consonants and language outcome in late talkers. What's more, the amount of vocalization that contained only vowels was negatively related to expressive language growth. Williams and Elbert (2003) presented a list of phonological behaviors that predict long-term speech delays in late talkers. These appear in Table 7-6.

Assessing phonological production in children with emerging language is very useful, then, both as a prognostic indicator and as an aid in choosing words to be included in the child's first lexicon, since Schwartz and Leonard (1982) have shown children are more likely to add words to their productive lexicons if the words contain consonants already in their phonetic repertoire. One option for phonological assessment at this age is the compilation of a consonant inventory (Shriberg & Kwiatkowski, 1980). This can be done by listening to a live or recorded vocalization sample and simply writing down each consonant that is used at least once in the sample, regardless of whether it appears in a conventional word, word approximation, or nonconventional vocalization. If a diary has been provided by the parents, a consonant inventory can be gathered from the "what it sounded like" column of the diary form. The consonant inventory can be used in two different ways:

1. Consonants already in the inventory can be used to select words to be included in the first lexicon to be taught to the child. Although there are other considerations, too—such as concepts the child has available for mapping onto words and the familiarity and communicative value of the words to be taught—choosing words that have sounds already in the child's repertoire greatly enhances the chances that the child will add the word to the productive lexicon (Schwartz & Leonard, 1982). The consonant inventory should be used primarily to select *words* to be taught, rather than as a way to identify *sounds* we should try to get the client to say. Children of this age have little phonological awareness, and there is not much evidence that children can learn sounds in isolation at this developmental level. Rather than trying to increase the consonant inventory at this stage, we would suggest using the consonant inventory to help choose words that will be easy for the child to learn. Later, after the child reaches a developmental

level of 3 or so and has more cognitive awareness, focused work on the acquisition of additional consonant sounds can be undertaken.

2. The number of consonants present in the inventory can be used as an index of severity of phonological delay. Paul and Jennings (1992) and Williams and Elbert (2003) reported that normal 18- to 24-month-olds produced an average of about 14 different consonants in a 10-minute communication sample, whereas 24- to 36-month-olds produced an average of 18. Children with small expressive vocabularies, however, produced significantly fewer consonant types: an average of six at 18 to 24 months and 10 at 24 to 36 months. Comparing a client's consonant inventory size with these data can help a clinician decide whether the child more closely resembles a normally speaking peer or a child with a significant language delay. This information can be useful in deciding whether to recommend early intervention.

Morris (2009) warns, however, that consonant inventories change from sample to sample, and advocates collecting samples at least 30 minutes in length to increase stability of the sample.

Another measure that may be helpful in phonological assessment is the syllable structure level (SSL), which was developed by Paul and Jennings (1992), based on Olswang, Stoel-Gammon, Coggins, and Carpenter's (1987) mean babbling level. This measure examines both intelligible words and nonconventional vocalizations. It is derived by rating 20 to 50 child vocalizations, each at one of the following three levels, in terms of canonical (syllable) structure:

Level 1: The vocalization is composed of a voiced vowel ([a]), voiced syllabic consonant ([l]), or CV syllable in which the consonant is a glottal stop or glide ([h], [w]).

Level 2: The vocalization is composed of a VC ([up]) or CVC with a single consonant type ([kek]), or a CV syllable that does not fit the criteria for level 1. Voicing differences in CVCs are disregarded (*toad* would be considered a level 2 vocalization).

Level 3: The vocalization is composed of syllables with two or more different consonant types, disregarding voicing differences ([pati] would be considered a level 3 vocalization; [dati] would be considered level 2).

The SSL is then computed by averaging the levels assigned, adding up all the ratings given to each vocalization, and dividing by the number of vocalizations rated.

Paul and Jennings (1992) found that SSLs for normally developing 24-month-olds were about 2.2, indicating that most utterances were at level 2 and some were at level 3. SSLs for toddlers

TABLE 7-6 Predictors of Long-Term Speech Delay in Late-Talkers at 30 to 35 Months

Phonological Characteristic	Description/Examples
Limited phonetic inventory	Order of acquisition of phonemes is delayed, not deviant; at 30–35 mo, late-talkers have only 6–9 different consonants
Simple syllable structures	Fewer syllables with more than one consonant or consonant clusters (Pharr et al., 2000)
More sound errors	Percent consonants correct <0.45
Greater inconsistency in substitution errors	Individual phonemes are produced in a variety of ways
Atypical errors	Unusual substitutions (/d/ / h/); vowel errors
Slow rate of resolution	Little change over the 24- to 36-mo time period

Adapted from Williams, A., & Elbert, M. (2003). A prospective longitudinal study of phonological development in late talkers. *Language, Speech and Hearing Services in Schools*, 34, 138-154.

with small expressive vocabularies, on the other hand, were about 1.7, showing that many of their utterances were at levels 1 and 2, but very few at level 3. Pharr et al. (2000) found that, at 24 months, most syllables produced by late talkers were at level 1 and fewer syllables had a final consonant, more than one consonant, or a consonant cluster.

Morris (2009) reported that SSL was a reliable measure within short (20 minutes) samples. Moreover, because they place less emphasis on accurate phonetic transcription, they are a good option for speech that is difficult to transcribe. Morris (2010) reviewed a range of studies that used SSL and concluded that it is a valid and reliable measure of speech development in 2-year-olds. The ability to include more than one consonant within an utterance, particularly in closed syllables, then, seems to be an important phonological milestone that 2-year-olds with slow language development are missing.

Computing an SSL from a communication sample or diary may be useful for determining whether a client is seriously limited in phonological skill. This can be done by simply rating each of the client's vocalizations according to the three levels described and averaging these ratings. If the average is less than 2, we can conclude that the child with emerging language is showing limited syllable structures. Alternatively, we might simply want to inspect the communication sample or diary form for any evidence of level 3 structures, those containing more than one consonant type. If more than 25% of syllables are at level 3 structures, we would be less likely to conclude that the child has a limitation in the development of canonical form. If fewer than 25% of the syllables are at level 3, however, and if we believe the sample we are inspecting is a valid reflection of the child's phonological performance, a deficit in syllable structures might be inferred. Some additional approaches to examining phonological complexity in early speech include Stoel-Gammon's (2010) *Word Complexity Measure* (WCM), Preston et al.'s (2011) *Weighted Speech Sound Accuracy* (WSSA) score, and the *Index of Phonetic Complexity* (IPC; Jakielski, Maytasse, & Doyle, 2006; Morris, 2009).

Whether we compute an SSL, look for the presence of level 3 syllable structures or use the WCM or IPC, a deficit in complexity of phonological production would lead us to try to elicit more advanced forms, first in imitative babbling and only later in conventional words. Data from Paul and Jennings (1992) indicated that the most common level 3 syllable types produced by normally speaking toddlers are C_1VC_2 ([pat]) and $C_1VC_2V(C)$ ([baki], [patIt], or [pati]). These kinds of productions can be elicited in back-and-forth babbling games. First the clinician can simply imitate the child's vocalization. Next, the clinician can expand the child's vocalization to include one of these more advanced syllable forms. If the child says [baba], the clinician can respond with [bata]. If the child imitates this expansion, the clinician can imitate it again, encouraging the child to repeat the more advanced syllable form. If not, the clinician can continue to produce the more advanced structure in response to the child's simpler one, giving additional opportunities for the child to take advantage of the model. Goldstein and Schwade (2008) showed that these kinds of interactions were effective in increasing vocal complexity in typically developing infants. It is important to remember that the goal of these activities is *not* to elicit particular sounds, but only to get the child to try to produce two different sounds within an utterance. If the child produces *any* two different sounds, lavish praise ought to be the consequence, regardless of whether the two sounds are the ones the clinician produced.

The two methods of phonological assessment we have been discussing are both examples of what Stoel-Gammon (1991) called *independent analyses*. That is, they look only at the child's productions themselves, not in relation to adult targets. *Relational analyses*, on the other hand, compare what the child produces with an adult form and identify whether it is right or wrong. Stoel-Gammon (1987, 1998), for example, showed that normally developing 24-month-olds are close to 70% accurate in their production of consonants, relative to adult target words, whereas late talkers have been found to be less than 50% accurate (Paul & Jennings, 1992; Williams & Elbert, 2003). Stoel-Gammon (1991) also reported limited vowel repertoires in children with language delays. Roberts, Rescorla, Giroux, and Stevens (1998) and Stoel-Gammon (1991) have shown, though, that many of these errors resolve spontaneously between 2 and 3 years of age. For this reason, Stoel-Gammon recommends using only independent analysis to evaluate phonology in children with developmental levels younger than 3 years. Relational analyses, such as examination of phonological process use (Preisser, Hodson, & Paden, 1988) or analysis of percent consonants correct (Shriberg & Kwiatkowski, 1982b), are best reserved for children who function above 3 years of age. One promising procedure in this area is McIntosh and Dodd's (2008) *Toddler Phonology Test*, a formal assessment involving production of 32 words, either spontaneously or in imitation. Although quantitative scores are not reliable in identifying toddlers with delayed speech, the types of errors seen at age 2 were predictive, so that children who used atypical error patterns (i.e., patterns *other than* cluster reduction, final consonant deletion, stopping, fronting, unstressed syllable deletion, gliding, and deaffrication) were likely to qualify as speech delayed at age 3.

Still, many children with 18- to 36-month developmental levels produce few words. Our goals are generally to increase their vocal production and to expand their vocabularies, without regard to phonological accuracy. Precise articulation and the relational assessments needed to assess it can wait. The two independent analyses we've talked about—collecting a consonant inventory and looking at the sophistication of syllable structures produced by the client—will be sufficient for most clients at the emerging language level. Both these measures are relatively easy to compute from live, recorded, or diary samples, and each contributes information that is useful for assessing prognosis, designing a program to increase the sophistication of the child's vocalizations, monitoring progress, and for choosing words that the child will be likely to incorporate into a first lexicon.

Assessing Lexical Production

Children at the 18- to 36-month developmental level who are referred for communication evaluation will probably be producing few intelligible words. There are, though, several ways to get an idea of the size and range of vocabulary these clients do produce. One is through language sampling, using the methods we have already discussed, such as observation of a play session, recorded communication samples, or parent diary recordings. These methods give us some notion of the words the child produces but are unlikely, because they are samples, to show us all the words the child says. Some of the screening measures we discussed earlier, including Rescorla's (1989) *Language Development Survey* and the *MacArthur-Bates Communicative Development Inventory* (Fenson et al., 2007) are well-constructed parent-report measures that can be used for this purpose (Eadie et al., 2010; Klee et al.,

1998; Rescorla, Mirak, & Singh, 2000; Rescorla, Ratner, Jusczyk, & Jusczyk, 2005; Thal, O'Hanlon, Clemmons, & Fralin, 1999). Parent report of expressive vocabulary size is, then, an easy-to-collect and useful index of the number of different words that a child with emerging language can produce. Both these instruments also divide words into semantic classes. This semantic class information can be used to decide what concepts and meanings the child is currently talking about and to aid in determining the concepts and categories for words that are available to be added to the child's lexicon.

A variety of general expressive communication measures also are given in [Appendix 7-1](#). Direct assessments of expressive language in this age range have, like the language sample procedures we discussed, the problem of representativeness. When a child fails to produce a form, we don't know whether that failure is a reflection of the fact that the form is really absent from the repertoire or whether the child just didn't feel like producing it. This problem is especially acute for children with emerging language for two reasons. First, their rate of communicative behavior is relatively low, so the samples we get from them are fairly sparse. Second, children in the emerging language stage often just don't comply with requests from adults, particularly with requests to talk or name things. For these reasons, parent-report instruments or those that allow parent report as one source of data are especially useful for this age group. The *Vineland Adaptive Behavior Scales II—Communication Domain* (Sparrow, Cicchetti, & Balla, 2005) is, like the vocabulary checklists we have been discussing, a parent-report instrument. It displays high correlation with direct measures of language use (Paul, Spangle-Looney, & Dahm, 1991; Rescorla & Paul, 1990) and is another measure that can be considered in examining expressive language in this age group.

Assessing Semantic-Syntactic Production

Most clients with emerging language have little to show in the way of productive syntax. If they are verbalizing at all, it is likely to be in the form of single words. In normal development, children do not begin to combine words until vocabulary size reaches about 50 words. Therefore, if a client is producing fewer than 50 words, we would be wiser to work on increasing expressive vocabulary size before trying to get the child to produce word combinations. When the productive lexicon reaches about 50 words, syntactic intervention becomes appropriate, if word combinations have not appeared spontaneously. Detailed productive syntactic assessment, then, is not likely to be an important part of our evaluation in the emerging language stage. Computing a mean length of utterance (MLU) is fairly easy for this age group; it will generally be either 0 or 1. But there may be some children with emerging language who have productive lexicons larger than 50 words or who are beginning to combine words into sentences. When this is the case, we want to look at two aspects of these combinations: the relative frequency of word combinations within a communication sample and the range of meanings or semantic relations expressed. Let's see how we might examine each of these parameters.

Relative Frequency of Word Combinations

To look at the relative frequency of single-word versus two-word utterances, we need to collect a fairly large sample of verbal production from the client. This may not be so easy. If a communication sample is being collected to look at expression of intents, a separate portion of the session needs to be reserved for recording

the interpretable one- and two-word combinations. The recording collected from a home sample by the family or from a clinic play or communication sample can also be transcribed and inspected for two-word combinations. If we use the diary method, we can note the relative proportions of one- and two-word utterances recorded by the parents from the several sessions during which they took data. We might ask the parents to be especially careful to record word combinations.

If the rate of word combinations is too great to be recorded easily from either a sample or by parents keeping a diary, it may be that the child is moving out of the emerging language stage into the next phase of language development. If this is the case, we need to do a more detailed assessment of syntactic skills, using methods such as those we'll discuss in Chapter 9 for children with developing language. Toddlers with a history of risk factors at birth who are being followed for communication development may present this happy picture. Rescorla, Dahlsgaard, and Roberts (2000) found that 30% to 40% of late-talking toddlers had moved into the normal range of syntactic production by age 3. If an at-risk toddler's MLU exceeds 1.5 at about 24 months, or if half the utterances contain word combinations, we are justified in feeling that a major hurdle toward normal development has been overcome. Further monitoring may be necessary, but the client is well on the way toward normal language acquisition.

For most clients with emerging language, though, frequency of word combinations is much lower. We can compute a proportion of word combinations by simply dividing the number of utterances containing more than one word by the total number of interpretable verbal utterances in any speech sample we can collect. This proportion gives us an idea of how frequently the child combines words. If the proportion is close to or exceeds 50%, we can conclude that the client is functioning at least at a 24-month level in terms of syntactic production. If the proportion of word combinations is much less than 50%, we can conclude that the client is functioning below this level. It would be surprising if a child with a very small expressive vocabulary (fewer than 50 words) used a lot of word combinations. Like the connection between lexical and phonological acquisition, the link between the acquisition of syntax and vocabulary size is usually quite close, too. Typically, all these aspects of early language acquisition proceed in tandem. However, there may be the unusual client for whom some separation of developmental strands has taken place. For this reason, we want to look at each of the areas of language individually.

Semantic Relations Expressed

When children begin combining two words in sentences, these combinations result in new meanings that are not present in the meaning of either of the words alone. For example, there is nothing about the word *doggy* or the word *bed* that means possession. But when the two words are combined into the utterance *doggy bed*, this utterance can convey a meaning of possession (it's the doggy's bed) if spoken in the right context. Further, children do not combine their words randomly but use consistent word order to denote the relations. This ability to combine words syntactically to produce new *semantic relations* that are not part of the meaning of either of the component words in the utterance is one of the accomplishments of normally developing children in the 18- to 36-month age range.

When children are producing some word combinations, it makes sense to examine the meanings expressed in these combinations. Generally, normally developing toddlers express a relatively

small range of semantic relations in their speech. Eight to 11 major ones (depending on which researcher's coding system you use) can usually account for the great majority of relations used by children in this age range. Table 7-7 gives the semantic relational categories used by Brown (1973) that are typically found in the speech of normally developing toddlers who are learning a variety of languages and dialects (Stockman & Vaughn-Cooke, 1986). Haynes and Shulman (1998b) reported that children with language disorders have been shown to produce these same relations when they begin to combine words.

One assessment method appropriate for this developmental level is Lahey's (1988) content/form assessment. This approach uses both semantic and syntactic information, gathered from the analysis of a spontaneous speech sample, to target goals in emerging content-form-use interactions. This method can provide a rich source of data for planning intervention targets and charting the progress of children in the emerging language stage. Detailed instructions for this method can be found in Lahey's (1988) text. Lee's (1974) Developmental Sentence Types (DST) procedure is another method of speech sample analysis appropriate for this stage.

Alternatively, we can look more narrowly at the expression of semantic relations in children with emerging language. Using this approach, we would first attempt to code each multiword utterance in our language sample (derived from an observation, recording, or parent diary) into one of the categories in Table 7-7. Utterances that did not fit any of these would be placed into an "other" classification. One way to start the analysis would be to look at the proportion of utterances we had to call "other." Normative research indicates that this should be about 30%. If it is more than 50%, we would want to inspect the "other" utterances to see whether they are encoding higher-level semantic relations having to do with concepts such as time (go now), manner (go fast), sequence (eat [then] drink), or causality (cry [because] hurt). If these higher-level relations are being conveyed frequently, they would suggest to us that the child is exhibiting some advanced cognitive development

in the presence of delayed expressive language. We would want to foster this advanced development with appropriate play contexts and attempt to provide the child with more conventional means for expressing these sophisticated notions.

If the proportion of "other" utterances is less than 40% or 50%, we then look at the distribution of relations expressed within the set of utterances coded according to Brown's (1973) categories. If a client is encoding a range of these relations, we conclude that the child is moving toward normal semantic and syntactic development. Intervention, if needed, would focus on increasing the vocabulary available for combining into multiword utterances. Even if the range of relations expressed is somewhat restricted, we would not necessarily conclude that the child is showing a deficit. Lahey (1988) discussed the fact that children sometimes show preferences for encoding certain semantic relations in early language development. Until developmental level exceeds 36 months, we should not discourage the client from these preferences. Rather, we should teach more words that the child can use to express them and provide increased opportunities in play contexts for the client to encode these relations with the new words. In addition, we can supply models in appropriate play contexts for the child to hear other relations expressed and give opportunities, through indirect language stimulation, for the child to imitate these models.

Box 7-3 provides a sample transcript from a 28-month-old child in the emerging language stage. You might like to try some of the semantic and syntactic analyses we've been discussing on this transcript. You can compute the relative frequency of word combinations. Then assign each word combination to one of the categories in Table 7-7 or to the "other" category. Compute the proportion of utterances rated "other" and examine the range of semantic relations expressed. Our analysis is given in Appendix 7-2.

In summary, assessing production in a child with emerging language involves looking at phonological skills, vocabulary size and content, and semantic-syntactic combinations. Typically, all these areas are closely related. Some children may show disconnections, though. Children with hearing impairment, for example, may have semantic relations and pragmatic intents that are more advanced than their syntax and phonology. Children like Joey may show just the opposite pattern, with relatively strong skills in language form and less development of semantic and pragmatic skills. For clients like these, clearly, it is important to have a complete picture of language skills in each area. Even when clients show the normal interrelatedness of these areas, though, we need to know something about each in order to plan the most effective program for improving expressive skills. Because lexical development is closely tied to phonology, we need to know what sounds and syllables the child can produce so that we can choose words appropriately. Because syntax usually does not begin until vocabulary size reaches 50 words, we need to look at the productive lexicon before making decisions about teaching word combinations, and so on. Even when there is little productive language to assess, it is our responsibility to find out as much as we can about what expression there is.

TABLE 7-7 Semantic Relational Categories Used by Brown (1973) to Account for the Majority of Word Combinations in Toddlers' Spontaneous Speech

Semantic Relation	Example
Attribute-entity	Big shoe
Possessor-possession	Mommy nose
Agent-action	Daddy hit
Action-object	Hit ball
Agent-object	Daddy ball
Demonstrative-entity	This ball
Entity-locative	Daddy chair [Daddy's in the chair.]
Action-locative	Throw chair [Throw it onto the chair.]
Recurrence	More milk
Nonexistence, denial, rejection	No cookie
Disappearance	Allgone cookie

DECISION MAKING BASED ON ASSESSMENT INFORMATION

The essence of the model of assessment of emerging language involves comparing a child's functioning in various areas of communicative development and using this information in developing

BOX 7-3 Sample Transcript from a 28-Month-Old Child (C) Collected during Free Play with Parent (P) Using Dollhouse Toys

P: Do you see the kitchen? C1: Yeah.	P: Are you making spaghetti for dinner? C15: Yeah.	P: Where's Daddy's clothes? C27: Mine upstairs.
P: What's this doll's name? C2: Name, Mom	P: Maybe lasagna? C16: Yeah. [Holds up small, white plastic box.]	P: Oh, in the closet? C28: Yeah.
C3: Name Cinderella.	P: Is it a cake? C17: No, that bed.	P: OK. C29: Daddy cowboy! [Holds up doll in cowboy suit]
P: Oh, that looks like a changing table. C4: Yeah.	P: Oh, should you put it in the bedroom? C18: Yeah.	P: What's this? C30: (um) window.
P: For the baby. C5: No, Mom, no.	P: Where's the bedroom? C19: Right here.	P: How many windows are in your room? C31: What?
P: Can you find a bed for the baby? C6: Yeah.	C20: Oh, don't fit.	P: How many windows are in your room? C32: No.
C7: No, here is.	P: Too big. C21: Mom.	C33: Hey, baby.
P: Where's the living room? C8: What?	P: What is it? C22: Baby.	P: Is Baby crying? C34: No.
P: Where is it, the living room? C9: Here is.	P: Oh, what's the baby's name? C23: Name.	P: Is Baby hungry? C35: Yeah.
P: Can I sit in the living room? C10: Yeah.	P: We know some new babies, don't we? C24: Yeah.	C36: Baby me hold.
C11: Here Daddy.	P: Auntie Barbie's gonna have a baby? C25: Yeah.	
P: What is this? C12: What that?	C26: Baby go in bed.	
P: I think it's a stove. C13: Yeah.		
P: There's the kitchen. C14: Mommy cook.		

a prognosis that will help us decide whether a child would benefit most from direct intervention or continued monitoring, as well as to help in devising a treatment plan. The model is schematized as a decision tree represented in Figure 7-5. Crais and Roberts (1991) and Whitehurst and Fischel (1994) also provided decision trees for planning intervention for children with emerging language. Olswang, Rodriguez, and Timler (1998) provided an alternative means of evaluating the need for intervention. In the model we've proposed, the decision process begins with the question of whether the child demonstrates functional or symbolic play behavior that would normally accompany the use of conventional language. If a nonspeaking client is not using these play behaviors, then intervention should focus not only on developing communication but also on modeling the use of objects for conventional and pretend play schemes. If these kinds of symbolic play are present, we then look at nonverbal communicative behavior. If the frequency and/or range of communicative behavior is found to be limited, we would use modeling and communication temptations to try to increase the frequency of intentional behavior in addition to heightening the rate of vocal production. These activities could either precede or accompany the development of early vocabulary. If the child appears to be a good nonverbal communicator but to lack the conventional verbal forms of communication, the issue of level of language comprehension is raised next. If comprehension skills are found to be below those expected for the level of communication demonstrated, then activities to foster receptive language skills, such as focused stimulation activities and indirect language stimulation, should be an important component of the management program.

If receptive language is adequate for developmental level, then we need to take the child's level of accumulated risk factors into account. Children without any other risk factors who are slow to

start talking have a good chance of "catching up" with their normally speaking peers by school age if their deficits are limited to expressive language; they begin to use some speech by 30 months; and their cognitive, symbolic, receptive, and communication skills are developing normally (Capone & McGregor, 2004; Ellis & Thal, 2008; Girolametto et al., 2001; Paul, 1996a; Thal, 1991; Whitehurst & Fischel, 1994). These children with circumscribed expressive language delays should be monitored closely throughout their third and fourth years of life. If expressive deficits persist through the preschool period, intervention options can be carefully discussed with parents (see Paul, 2000b; Whitehurst & Fischel, 1994, for suggestions). For children who have known developmental disorders or other risk factors such as those listed in Figure 7-5 or Box 7-1, though, early intervention seems appropriate even if only expressive language is delayed. The consequences of language delay for a child's social and cognitive development can be pervasive and language is one of the most vulnerable functions in young children's development. Providing help to children who are slow to learn to talk serves an important secondary prevention function and ought to be considered if the child is known to be at risk (Paul & Roth, 2011). For children with severe language deficits who are older than 3 years but still in the phase of emerging language, intervention or tertiary prevention is always appropriate, of course.

FROM ASSESSMENT TO INTERVENTION

The decision tree in Figure 7-5 can be used to help us decide when to recommend intervention for a child with emerging language. Once we have decided to provide intervention, of what should the intervention consist and how should it be delivered? We have

FIGURE 7-5 Decision tree for intervention planning in the emerging language stage.

already discussed some suggestions about appropriate targets and methods of intervention for this developmental level, but let's address these issues more directly now.

Family-Centered Practice

Most clients in the emerging language stage will, like their prelinguistic counterparts, be served through an Individual Family Service Plan (IFSP) designed by a team of professionals, as mandated by IDEA. Unless the SLP is designated as the case manager, we provide just one part of that plan: the data on language assessment and the family-based services in communication development. The form of the IFSP for a child with emerging language is very similar to the one designed for a prelinguistic child (see Chapter 6 for examples), except that the section on planning for transition to preschool services is more detailed. The issues discussed in developing an IFSP for a child with emerging language are very similar to those discussed in Chapter 6.

Parental involvement increases the effectiveness of intervention for children with emerging language.

One issue we'll need to consider in the development of the intervention plan is the parent's role. When fostering communication at the prelinguistic stage for developmentally young children, we definitely want to involve the parent as the primary agent of the intervention. The communicative routines that the young prelinguistic child needs are not hard to learn; in fact, they come naturally to most parents. The management program for children at the emerging language stage is somewhat more focused and specific, though. Are parents still the ideal primary agents of intervention at this stage?

Many programs have been developed for addressing communication disorders in children with emerging language that use parents as the primary agents of intervention. Some of these programs involve teaching parents clinician-directed or behaviorist approaches to eliciting language (Kemper, 1980; MacDonald, Blott, Gordon, Spiegel, & Hartmann, 1974; MacDonald, 1978; Whitehurst et al., 1991). Others teach parents to use hybrid (Cheseldine & McConkey, 1979; Clezy, 1979; Girolametto, Pearce, & Weitzman, 1996; Ingersoll & Dvortczak, 2010; Lederer, 2001; Peterson, Carta, & Greenwood, 2005; Wulz, Hall, & Klein, 1983; Yoder & Warren, 1998, 2002) or child-centered methods (Chandler, Christie, Newson, & Prevezer, 2002; Fey, Newhoff, & Cole, 1978; Hubbell, 1981; Kaiser & Hemmeter, 1996; MacDonald, 1989; Manolson, 1992; Norris & Hoffman, 1990b; Seitz & Marcus, 1976; Yoder & Warren, 1998). The rationale for parent involvement includes the notion that parent-implemented intervention will promote more generalization and may improve other aspects of functioning, such as social skills, in addition to improving communication (Kaiser, 1993; Paul, 2000b). It also grows out of the concept of family-centered practice, which encourages family involvement in all aspects of service delivery (Crais & Calculator, 1998; Rini & Hindenlang, 2006). Unfortunately, the rationale sometimes includes the notion that part of the child's communication problem resides in the parent's communication style. Many people, even SLPs, believe that children fail to start talking because people in their environment anticipate their needs and the child has no incentive to learn language. From this point of view, the way to improve the child's communication is to improve the parent's.

But remember: *normally* speaking children don't *need* to talk either, in the sense that their needs, too, are anticipated and their nonverbal communications are consistently responded to and rewarded. They learn to talk because it is part of their biologically programmed development (Locke, 2005; Pinker, 1994). Data on mother-child interactions (Desmarais, Sylvestre, Meyer, Bairati, & Rouleau, 2008; Paul & Elwood, 1991; Vigil et al., 2005) showed very few differences in linguistic input to normally speaking toddlers and their late-talking peers. Still, it is possible, as Girolametto et al. (1996, 1999) and Whitehurst et al. (1991) have shown, to maximize the quality of parental input to a child in the emerging language period. Maximizing their input does not mean that they were doing anything wrong in the first place, nor does it mean that the entire burden of intervening in their child's communication disorder should fall on the parents' shoulders. There may be times when parents should *not* be teachers but should instead make their child feel understood and accepted, even if his or her speech is not working well. However, helping parents provide the most beneficial input to their child is certainly an attainable goal. Much of the intervention we will provide to children in the emerging language period can be done successfully by parents with some training and monitoring from the SLP. Family-centered practice dictates that we encourage parents to do as much of the intervention as they feel is appropriate for them and their child. In cases in which they do not

feel comfortable doing so, it is appropriate for the SLP or another intervention agent to be provided. However, as Robertson and Weismer (1999) showed, clinician-delivered intervention can also have important secondary effects, such as improving overall social skills and reducing parental stress. We need to keep both the costs and benefits of parent-delivered intervention in mind when we plan programs for these children.

Appendix 7-3 lists printed materials that clinicians can use to help parents maximize the communicative and cognitive value of their interactions with their children. Appendix 7-4 lists videotaped presentations that have been developed to help parents understand their toddlers' development and to communicate more effectively. *Exceptional Parent* magazine also contains a wealth of helpful information for parents of children with disabilities. These resources can be used by the clinician to involve parents in fostering their child's growth, in understanding the complexity and wonder of development, and in providing the most appropriate forms of play and interaction of which their child can take advantage.

The family can and should be actively involved in setting goals for their child's intervention program, and the clinician should consult the parents as to what they most want their child to learn and how much of the intervention they would like to deliver themselves. Parent training that incorporates materials such as those in Appendices 7-3 and 7-4 can be used by the clinician in a consultative role to maximize the impact of parent-child communication on the child's development. In addition, teaching or encouraging parents to use indirect language stimulation techniques, using either video or printed materials that address this area (some can be found in Appendices 7-3 and 7-4), will be particularly useful for optimizing the linguistic input the child with emerging language receives. However, we believe that there also is a role for more focused, direct intervention for a child with emerging language who meets the criteria we've discussed for entrance into early communication intervention. Let's look at some of the specific goals and methods that might be used in this intervention.

PRODUCTS, PROCEDURES, AND CONTEXTS OF INTERVENTION FOR CHILDREN WITH EMERGING LANGUAGE

Intervention Products: Goals for Emerging Language

We want to address several areas of communicative development in children with emerging language. We select these areas based on the results of our assessment, following our decision tree structure. Depending on these results, we will decide to address one or more of the following areas in the intervention plan: the development of functional and symbolic play and gesture; the use of intentional communicative behavior; language comprehension; and production of sounds, words, and word combinations. As we discuss each of these areas, suggestions for procedures and contexts for the intervention program also will be presented.

Developing Play and Gesture

If the child is not demonstrating any appropriate or semi-appropriate use of objects or symbolic play and gestures listed in Tables 7-2 and 7-3, a foundation for symbolic function in reciprocity and anticipatory sets may need to be established. Using techniques outlined in Chapter 6 can help to establish this basis. What if observation of play and gesture indicates that the child is already showing reciprocal behavior, such as turn-taking in back-and-forth babbling

games, and anticipates actions in baby games, such as peek-a-boo, but is not yet using the functional and symbolic behaviors? This child is probably ready to be encouraged to use the next levels of symbolic behavior, such as early conventional and symbolic play and deictic gestures. Barton and Wolery (2008) identified studies that taught play behaviors to children with disabilities, and found studies that successfully employed physical prompts, live and video modeling, as well as verbal prompting to teach play behaviors in a hierarchy given in Table 7-8. They reported significant increases in pretend behaviors related to adult modeling and/or prompting using materials typically found in early childhood classrooms. These findings suggest play behaviors can be effectively taught to very young children. Deictic and representational gestures can be modeled in a similar way. For example, if the child bangs a cup, the clinician can imitate the banging, then hold the cup up to the child's face to show it, saying "Cup!" If developing conventional and symbolic play and gesture is one goal of the intervention, this is an ideal context for parent involvement. Parents can easily be shown how to model these play and gesture behaviors, and engaging in them provides an ideal setting for positive, facilitative parent-child interactions. Encouraging parents to use gestures as they talk with their toddlers, both to indicate referents for words (by pointing to what they are naming) and to serve as accompaniments to words (such as holding up two fingers in a "V" when they are talking about a rabbit) can enhance children's word learning (McGregor, 2008).

Using Intentional Communicative Behaviors

You'll remember that we evaluated the frequency, form, and functional range of expression of communication intentions in the child with emerging language. Intervention aimed at increasing the frequency of intentional communication bumps us up against what Hubbell (1981) called the "*be spontaneous paradox*" (p. 250). We

Eliciting intentional behavior is often a communication goal in the emerging language stage.

want children to *initiate* communication, but we have to somehow *get* them to do it. Here we can use communication temptations, such as those of Wetherby and Prizant (1989) listed in Box 6-5. In providing communication temptations, we are using a hybrid method of intervention. We do not require a specific response (although there is one

TABLE 7-8 Taxonomy of Play Behaviors to be Taught in Intervention for Toddlers

Play Type	Definition	Example
Functional play with pretense	Use of actual or miniature objects in the manner in which they were intended without the reality-based outcome.	Pretending to eat from empty spoon.
SUBSTITUTION		
Object substitution	Use of one object as if it were a different object.	Holding a block to the ear and pretending to talk on the phone.
Imagining absent objects	Performing an action as if an object were present in the object's absence.	Holding an empty hand to the ear and pretending to talk on the phone.
Assigning absent attributes	Assigning dramatic roles or emotions to the self, others, or inanimate objects.	Hugging and comforting doll that is "crying."
SEQUENCES		
Functional play sequence	A series of at least two functional play with pretend actions related to same theme or routine.	Putting a doll on a bed then covering it with a blanket.
Substitution sequence	A series of at least two substitution actions related to same theme or routine.	Putting a doll on a piece of paper ("bed") and covering it with a washcloth ("blanket").
TALK AND PLAY		
Confirmatory vocalizations	Identifying specific roles children are acting out; assigning attributes to themselves; or planning, mapping, or confirming pretend play behaviors.	"You be the doctor and I'll be the mommy."
Scripts	Verbalizations taught <i>via</i> a script (targeted behaviors).	"Tell the storekeeper, 'I need some milk.'"

Based on Barton, E. E., & Wolery, M. (2008). Teaching pretend play to children with disabilities. *Topics in Early Childhood Special Education*, 28(2), 109-125.

we are hoping for), but we do structure the situation and provide multiple opportunities and models for the child. An excellent way to involve parents in this aspect of the intervention is to demonstrate the communication temptation to the parent and ask the parent to respond as we want the client to respond. If we hand the parent the clear, closed container, for example, we can let the parent know that we want her to hand it back and use a direct gaze, questioning expression, or simple single-word request (“Help”). After modeling this several times, we can hand the container to the client.

Another hybrid approach to increasing the rate of communication is to use the milieu teaching techniques discussed in Chapter 3. Warren and Yoder (1998) and Yoder and Warren (2002) trained parents to use what they called prelinguistic milieu teaching (PMT) to increase intentional communication in children with developmental delays. The method follows the basic principles of milieu teaching. It involves arranging

the environment to elicit child communication, focusing on and following the child’s attentional lead, embedding instruction in ongoing interaction, focusing on specific target behaviors, and using prompts and reinforcement to elicit and maintain communicative behaviors. An important component of this approach is to provide a long time for the client to emit a response (Olswang & Bain [1991] suggested 15 seconds). Warren and Yoder found the method to be highly effective, particularly for children with mothers who were already quite responsive to the children’s communicative attempts. Fey et al. (2006) also found significant increases in the number of intentional communication acts for children who experienced PMT with parent training, relative to a “treatment as usual group.” PMT, then, appears to be a very promising practice for improving communication for very young children with a range of developmental delays. Some specific methods used in this approach appear in Box 7-4.

BOX 7-4 Prelinguistic Milieu Teaching Methods

ARRANGING THE ENVIRONMENT

- Place desired materials in view but out of reach.
- Place materials where adult assistance is necessary to obtain them (such as in a tightly closed, clear plastic jar).
- Violate the expected order of events (e.g., give the child a shoe to put on before giving a sock).

FOLLOWING THE CHILD’S ATTENTIONAL LEAD

- Attend to and talk about toys selected by the child from an array.
- Reduce adult behavior to child’s rate of initiation, even if this means long periods of silence.
- Use contingent motor imitation—an exact, reduced, or slightly expanded imitation of a child’s motor act immediately after the child’s production to establish early turn-taking.
- Use contingent vocal imitation—following a child’s vocalization with a partial, exact, or modified adult vocal production (e.g., if the child says “aaah,” the adult can say, “aah” or “baa”).

BUILDING SOCIAL ROUTINES

- Engage the child in repetitive, predictable games, such as “patty-cake” or “peek-a-boo”; encourage parents to play the game at least once a day with the child.
- Vary the game slightly (e.g., if the child has learned “patty-cake,” change it to “Bake me a cake as S-L-O-W as you can,” with a corresponding change in the pace of the song).

USE SPECIFIC CONSEQUENCES

- Provide the following specific consequences in teaching episodes that are brief, positive, and embedded within the ongoing interaction:

Prompts

- *Time delay prompts:* Nonverbal prompts that interrupt an ongoing turn-taking routine (e.g., if the child and adult are rolling a ball back and forth, the adult can hold onto the ball instead of returning it and wait with an expectant look for the child to initiate a request to continue).
- *Gaze intersection:* To establish eye contact, the adult moves his or her head into the gaze of the child. This is faded out as the child begins to engage in eye contact more regularly.
- *Verbal prompts:* Attempts to elicit communication, such as an open-ended question (“What?”) or directive statement (“Look at me.”).

Models

- *Vocal models:* Delayed imitations of sounds that the adult has heard the child use. If the child is heard saying “ba,” for example, the adult can use “ba” at another time to try to elicit a vocalization from the child.
- *Gestural models:* Encourage the child to use presymbolic gestures by modeling them at appropriate times (e.g., if a plane passes overhead, the adult can point up to it, as a model of nonverbal commenting).

Natural Consequences

- Be sure the child achieves any intent expressed. If the child expresses a protest, honor it by ceasing the protested action.
- Provide any object the child requests and attend to anything on which the child is seeking joint attention.
- Provide acknowledgment of communication. Smile, look at, or comment on any intentional behavior of the child. Make sure the child knows the message was received.
- Provide linguistic mapping. Use simple language to “translate” a child’s nonverbal intention to words. If the child holds up a cup, respond, “It’s a cup! I’m glad you showed me!”

Routine or script therapy also can be used. Here we would establish routines in games or day-to-day activities and then playfully violate the routine in the hope of eliciting a protest or correction from the client. Social games such as “peek-a-boo” and “Gonna getcha” work well. Sussman’s (1999) book and accompanying video provide a variety of ideas for these activities that can easily be taught to parents. Other resources available from the Hanen Center (www.hanen.org) can also be useful in parent education. Parents can observe the clinician engage in these kinds of activities and be encouraged to try them during routines in the home.

If the child is showing low rates of communication overall and our goal is simply to increase the frequency of any kind of intentionality, we must be prepared to accept any form of behavior as conveying an intention. In fact, if the child does not give us any clear sign of communication, Prizant (1991) suggested that we impute intent to some behavior we do observe, treat it as communicative, and respond accordingly. In this way we can begin to shape the child’s behavior into communication.

Another aspect of expression of communicative intent that we addressed in assessment involved the range of intentions expressed. If assessment indicates that a child is expressing a restricted range of intentional functions, it is important to remember to work toward eliciting both proto-imperative and proto-declarative functions in an intervention program. Proto-imperatives are often addressed first because they are easier to elicit. We can use many of the techniques in [Box 7-4](#) for arranging the environment to encourage their production. Warren and Yoder (1998) also suggest establishing social routines, then having the adult withhold a turn and look expectantly at the child or provide a verbal prompt, such as “What do you want?” to encourage the child’s production. If this fails, the adult might use gaze intersection or a gestural model (see [Box 7-4](#)) to assist the child.

While the proto-imperatives are often targeted first, it is the proto-declaratives that more closely resemble the great majority of conversational speech acts. These acts also are less frequent in the communication of children with a variety of disabilities (Adamson & Chance, 1998; Rescorla & Mirren, 1998; Wetherby et al., 2004; Wetherby, Yonclas, & Bryan, 1989), although they are much more frequent than requests in typical children (Paul & Shiffer, 1991). For these reasons, it is especially important that we encourage the production of proto-declarative acts when attempting to broaden the range of expression of intentions. Warren and Yoder suggest that, because proto-declaratives involve sharing states of feeling and attention, it is important to develop a strong positive relationship with the child. Once this relationship is established, they advocate introducing novel events or objects to the child to encourage comments. New toys can be placed within established routines (rolling a car instead of a ball). Routines also can be sabotaged with silly or unusual events, such as pouring juice into a bowl, instead of a cup, at snack time. Adults also can pay less than the normal amount of attention to the client by backing away or facing away from the child during an interaction. This forces the child to do something to regain the adult’s attention (Note that this technique will generally not work so well with children with ASD, who may be relatively indifferent to adult attention). Adults also can pretend not to notice something the child has directed our attention to or can begin to comply with a request and fail to finish. Then the child needs to get our attention back to complete the task or game. These kinds of activities can help children learn how to direct other people’s attention to topics on which they are focused. Warren and Yoder suggest continuing these kinds of activities until the child produces more than one communicative act per minute. When this milestone is reached, we can begin to focus on initial symbolic communication.

For children who show relatively frequent expressions of a range of proto-imperative and proto-declarative functions but use only gestures as the form of their expression, we want to increase the maturity of the mode of communication. With children for whom speech seems a reasonable goal, we will attempt to elicit vocalizations, and eventually conventional words. Here our approach must be somewhat different than the one we used to encourage intentional communication. In this case, instead of responding to all the child’s actions as if they were communicative, we want to “up the ante” and withhold responding until the child produces some vocal behavior. Capone and McGregor (2004) suggest that we first identify concepts and intentions the child is already expressing with gestures. Since these are early symbolic behaviors, they should be within the child’s zone of proximal development for expression with a more mature form. They suggest we present higher level forms along with an imitation of the child’s gesture, to help make the connection between the child’s current symbolic representation and the new word we would like to become a symbol for the same idea. We don’t want to ignore gestures, though, as they may be the only way the child has at present to express wants and needs. Rather than trying to “extinguish” gesture use, we would be wiser to help children augment their gestural communication with increasingly mature vocalization. Using manual signs may be a bridge from gestures to symbolic communication. DiCarlo, Stricklin, Banajee, and Reid (2001) and Toth (2009) showed that teachers’ using manual signs along with speech led to increases in communicative interactions by toddlers with disabilities.

Whitehurst et al. (1991) suggested, further, that vocal forms of communication containing only vowels actually compete with the development of linguistic forms of communication. In other words, one type of vocalization is not as good as another. Only those vocalizations that contain consonants help to move the child in the direction of speech. This would suggest that vowel-only forms of vocalization, such as grunts, whines, and “uh-uh”s, ought to be treated no differently from gestures. When the child produces these forms of communication, we should first acknowledge that we perceive the child’s intention by saying something such as, “You want it. Tell me.” As a first step, any vocal behavior will be acceptable as long as it contains a consonant. As soon as clients produce a vocalization including a consonant, we can give them what they want or engage in joint attention. If they continue only to gesture or produce a vowel-only vocalization, these attempts can be ignored and further prompts for speech-like productions can be given. Once some consonant productions have been elicited, we can “up the ante” again and require a closer approximation to a conventional word.

There is one exception to this general series of procedures. That involves clients who use maladaptive means of expressing their intentions. Some clients, for example, use self-abusive behavior to get attention or to express boredom with a task. Others may use aggressive behavior to request objects. These forms of behavior are certainly communicative and ought to be understood as such. But because of the inherent danger of such behaviors, we will not be able to simply accept or ignore the maladaptive form of expression. Functional communication training has been shown to reduce these behaviors in toddlers, as it does in older children (Dunlap, Ester, Langhans, & Fox, 2006), and the advantage of managing these behaviors early is that they are less likely to escalate. Again, we always want to acknowledge to the client that the message was received; however, in the case of maladaptive forms of communication, we need to provide an alternative means quickly and to make clear that the form the client used was not acceptable. If a client, for example, requests a snack by grabbing food from another client, we

can say, “I see. You want it. Point to it, and I’ll give you one. Like this. Now you show me.” If the child uses self-injurious behavior to request the end of an intervention session, the clinician might say, “No. Don’t scratch. You’re tired. Show me (demonstrate a gesture, like putting face on hands as if sleepy). Then I’ll know you’re tired. We can stop then. You show me.” It is important, of course, once these more acceptable forms of expression have been acquired, that we honor them. If the child uses the new signal we’ve taught to request an end to an activity, then we need to end it. Otherwise, the signal will not have been an effective means of communication and the old maladaptive means will reappear.

All the approaches we have been discussing for increasing the frequency, range, and maturity of communicative behavior involve, to some extent, a refusal on the adult’s part to anticipate the child’s needs and a delaying of the adult’s provision of goods and services to the child. Should parents be providing this kind of intervention? Family-centered practice dictates that parents be involved in the decision about who should deliver this and any other form of intervention. We should discuss this issue with parents and ask whether they are comfortable behaving this way with their child. These discussions also should emphasize that it was not the parents’ willingness to respond to the child’s immature forms of communication that caused the problem. We would suggest, too, that regardless of who provides the intervention, parents should be encouraged to continue to anticipate and respond to the child’s needs, at least some of the time, and to feel that they do not have to provide this aspect of the intervention if that is their preference. Again, we want the child to feel that the parent can be relied on to understand and accept the child’s attempts to get messages across. Occasional playful violations of routines and communication temptation games are appropriate activities for parents, but children also should be able to feel that their parents will respond when they communicate with them, even if the attempts are immature. This is one area in which direct service by a clinician may be appropriate, until the child establishes a repertoire of consonant-containing vocalizations that are used for communication. Once this repertoire is established, parents may be able take over and up the ante to requiring these more speech-like forms in their own communication with the child.

Not all practitioners accept this view. Whitehurst et al. (1991), for example, argued that parents should be taught to ignore all gestures and vowel-only communication in these children. They advocated giving parents structured activities to do with the child to elicit speech. As in many areas of language pathology, this is an issue about which experienced clinicians disagree. Whitehurst et al.’s suggestions for parent activities are detailed in Table 7-9.

Developing Receptive Language

In Chapter 3, we said that intervention should focus primarily on productive skills, but that an input component ought to be included in the intervention program when comprehension deficits are identified. Indirect language stimulation (ILS) is one form of this structured input. ILS is especially appropriate for clients in the 18- to 36-month developmental range and can be used to provide multiple opportunities for the child to observe how language works to map the nonlinguistic context onto words. It allows the client to try out comprehension strategies and to develop expectations about conversational structure. It also can be combined with efforts to develop play skills by providing ILS in the context of facilitative play interactions. This aspect of the intervention is, in our view, particularly well suited to using parents as intervention agents. ILS is an ideal vehicle for giving the child a clear set of examples for

TABLE 7-9 Suggestions for a Parent-Administered Program of Early Language Intervention: First Words

Biweekly Assignment	Activity
1	Forced choice: Ask the child to choose between a liked and disliked object. Give the desired object only if the child tries to label it or imitates parent labeling it.
2	Develop vocabulary: Clinician chooses 20 words to begin vocabulary; parent asks <i>wh-</i> questions when child is attending to the referent for one of these words. Parent gives item or complies with child request only if child tries to label item or imitates parent’s label.
3	Incidental teaching: Parent asks child to label or imitate parent’s labeling any object or activity child is attending to or requests, and over which parent has control.

Adapted from Whitehurst, G., Fischel, J., Lonigan, C., Valdez-Menchaca, M., Arnold, D., & Smith, M. (1991). Treatment of early expressive language delay: If, when, and how. *Topics in Language Disorders, 11*, 55-68.

how language can be used to describe experience. It allows, but does not require, clients to try out this new understanding in their own production.

Reese, Sparks, & Leyva (2010) reviewed a range of studies that demonstrate parent training has the capacity to improve children’s language and literacy. Parents can be trained to use ILS techniques by taking advantage of some of the materials in [Appendices 7-3 and 7-4](#). The Hanen Program (Girolametto & Weitzman, 2006) has been particularly successful in providing this kind of training and publishes books for parents (Manolson, 1992, 1995) in English, Spanish, and French. Prizant (1991) suggested that training for parents in ILS should focus on helping the parent learn to follow the child’s lead by imitating actions, sounds, and words the child produces and providing words to match the child’s actions and activities. Parents need to be made aware of the importance of letting the child choose the topic, activity, or material and of being sure to comment on something the child is already doing.

The standard ILS techniques outlined in Chapter 3—such as expansion, extension, recasts, and open-ended and verbal reflective questions—can be taught to parents through modeling. Although parents normally supply these kinds of input to their toddlers, we want to encourage parents of clients with emerging language to provide *super-normal* levels of these facilitative stimuli. Explaining to the parents that we are trying to provide very high levels of facilitative input can help to allay any lingering suspicion parents may have that we feel they have failed to give adequate stimulation to the child. Our research on maternal linguistic input to toddlers (Paul & Elwood, 1991) suggested that one of the few ways that parents’ interactions with normally developing toddlers differ from those with children who have slow language development is that the mothers of normally developing toddlers get more speech from their children. This in turn gives them more opportunities to expand and extend the child’s remarks. You may remember that we said in Chapter 3 that these expansions and extensions are some of the

most efficient types of input for encouraging language acquisition. So one important way we can influence the child's linguistic environment is to ask the parents to expand or extend just about anything the child says. Furthermore, we can instruct parents to provide simple one-word labels for whatever the child is focusing on or referring to with preverbal communication. They can then expand or extend their own one-word label, modeling how simple language can be built upon and used. For example, if the child is looking at a doll, the parent can say, "Doll. Pretty doll! It's a pretty doll." Fey (1986) provided guidelines for training parents to understand the goals and methods of ILS. These are summarized in [Box 7-5](#). The relations between receptive and expressive language also are important to emphasize to parents. Although lexical production in clients with emerging language may be quite limited, we want to provide a broad range of models in play and other facilitative contexts to build receptive vocabulary. Getting a child to say words is not the only goal of ILS.

Developing Sounds, Words, and Word Combinations

Increasing Phonological Skills

The primary goal of phonological intervention in the earliest stages of language development is the enlargement of the consonant inventory and the range of syllable shapes the child can produce. Goldstein and Schwade (2008), as well as a review by Dunst, Gorman, and Hamby (2010), showed that imitating an infant's vocalizations had large effects on increasing infants' vocalizations. For the child with fewer than 50 words in expressive vocabulary, this enlargement can take place in the context of back-and-forth babbling games. These games involve, first, having the clinician simply imitate the child's vocalization. Once a back-and-forth imitation pattern is established, the clinician can introduce a new consonant into the babble and produce it for the child to imitate. New consonants that are added would be selected on the basis of the order of acquisition of consonants by normally developing children. Fasolo, Majorano, and D'Odorico, (2008), as well as Paul and Jennings (1992), found that late-talking toddlers acquire

consonants and syllable shapes in the same order as normally developing children do, but at a slower rate. By 18 to 24 months the late talkers produce most stop, nasal, and glide consonants, but few fricatives or liquids. So a clinician working to increase the phonetic inventory of a child with emerging language would first attempt to fill out the stop and nasal inventory, providing models for the child of any stops or nasals that were currently absent. If, for example, the client were producing only front stops in babble, the clinician would respond to the child's /bababa/ with /gagaga/. Once the full range of stop and nasal consonants is present in the child's babbling repertoire, the clinician can begin introducing some fricatives. It's important to remember that even though we are modeling sounds in developmental order, the goal of these activities is *not* to get the child to produce particular sounds, but only to increase the consonant inventory. Any new consonant produced, even if it is not the one modeled by the clinician, should be rewarded. Work on expanding the range of syllable shapes would proceed in an analogous way.

When speech is a goal for children at the 18- to 36-month developmental level, phonological work should focus primarily on expanding the repertoire of sounds and syllable shapes, rather than on correcting errors relative to adult target words. Normally developing children at this developmental level still use a variety of processes to simplify their speech (Bernthal & Bankson, 2004; McLeod et al., 2001; Roulstone et al., 2002). Any conventional word approximations that children with developmental delays are producing ought to be rewarded, not corrected. When expressive vocabulary and sentence length increase, there will be ample opportunity to work toward correct articulation. At the emerging language stage of development, the goal is to get the child talking and to increase the range of phonological structures available to support this talk.

Developing a First Lexicon

In Chapter 3 we discussed some of the considerations in selecting the first words to teach to children with small expressive vocabularies. These considerations include choosing words that are similar to those used first by normally developing children. Nelson (1973) found that close to one half of normally developing children's first words are nouns. These nouns include the child's own name and names of pets and family members, names for objects the child acts on directly (*shoe, spoon*), names for body parts (*nose, belly button*) and preferred foods (*cookie, juice*), labels for objects that move and change (*ball, light*), and for social games and routines (*hi, bye-bye, and patty-cake*) (Owens, 2009).

Nelson's data, though, suggested that the other half of children's first words are *not* nouns. Lahey and Bloom (1977) also emphasized the importance of teaching first words not just as labels for objects but also for other kinds of communication. They stressed the need to teach words that can be used to talk about the relations among objects. In fact, Banajee, DiCarlo, and Stricklin (2003) found that none of the most commonly used words in toddlers' vocabularies were nouns; instead they consisted of pronouns, (*I, you*), function words (*that, the*), verbs (*help, is*) and relational words (*more, all done*). Teaching these kinds of words gives the child the opportunity to express more communicative functions than simply naming. It also provides a set of words that can be readily combined with others into two-word utterances when the child is ready to make that step, so that a whole new set of vocabulary items would not have to be taught when the time arrives to make the transition to syntax. [Table 7-10](#) presents the words found to be most common in children's early lexicons. These would be good words to include when teaching first words to children with emerging language.

BOX 7-5 Guidelines for Parent Training

1. Be sure parents understand specific goals before beginning training.
2. Involve as many family members and caregivers as are willing to participate in the intervention.
3. Delineate parent and clinician responsibilities clearly.
4. Explain the purpose of all procedures.
5. Collect baseline data.
6. Model procedures for the parent; observe parent using procedures.
7. Provide feedback to parent, using videotape or group-training procedures.
8. Monitor the parent's use of the procedures, using direct observation or audio recorded by the parent during intervention sessions in the home.
9. Encourage parents to make incidental use of the procedures in natural day-to-day activities.
10. Maintain regular contact with families.
11. Monitor the effectiveness of the intervention.

TABLE 7-10 Words for a First Lexicon

Communicative Function to be Served	Relational Word	Substantive Word
Rejection, nonexistence, or disappearance	<i>No, allgone, away</i>	
Cessation or prohibition	<i>No, stop, alldone</i>	
Recurrence	<i>More, again</i>	
Existence	<i>This, that, there, what</i>	
Action on objects	<i>Get, do, make, throw, eat, find, draw, fix, wash, kiss, bump, help</i>	
Locative action	<i>Put, take, up, down, out, fit, sit, fall, go, dump, turn, in, on, here, out, off</i>	
Attribution	<i>Big, hot, pretty, dirty, some</i>	
Naming	<i>I, it, you</i>	Objects child acts on (<i>shoe, cup</i>) Objects that move (<i>dog, car</i>) Familiar people (<i>mom, dad, sibling names</i>)
Possession, commenting	<i>My, mine, want</i>	
Social interaction		<i>Hi, bye-bye, night-night, yes</i>

Adapted from Lahey, M., & Bloom, L. (1977). Planning a first lexicon: Which words to teach first. *Journal of Speech and Hearing Disorders*, 42, 340-350; Lahey, M. (1988). *Language disorders and language development*. New York: Macmillan; Banajee, M., DiCarlo, C., & Stricklin, S. (2003). Core vocabulary determination for toddlers. *Augmentative and Alternative Communication*, 19, 67-73.

An important consideration in choosing words for a first lexicon is that first words are functional and fulfill a broad range of communicative purposes (Owens, 2009). We want to teach children words that they can make use of often to accomplish their social goals. We don't want word training to consist of the clinician asking the child, "What is this?" since this kind of format is unlikely to teach the child how to use the word in the real communicative world.

MacDonald (1989) suggested further that words be chosen that encode ideas and interests children already have. These ideas and interests can be identified through analysis of play behavior. If, for example, a child demonstrates driving cars during the play assessment, *drive* would be an accessible word, although simplified pronunciation (/dai/) should be expected.

One further consideration in choosing a first lexicon has already been mentioned: the phonological shape and composition of the words to be taught. You'll notice that most of the words in Table 7-10 have simple, one-syllable CV or CVC shapes. These restrictions are appropriate for an early lexicon. In addition, when planning a lexicon for a particular client, it is important to match the words taught to the child's consonant inventory. If only stops /b/, /p/, and /g/ and the glides /h/ and /w/ are present in the inventory, then first words ought to contain those sounds primarily, at least in initial position. *Hi* and *bye-bye* would be good choices. So would *go, get, put, allgone, and bump*. Later, as new sounds enter the inventory by means of phonological work in back-and-forth babbling activities, new words containing those sounds can be added.

What are the best procedures for increasing early vocabulary? As with any language goal, we have clinician-directed, child-centered, and hybrid methods available to us. Many clinicians (Lahey, 1988; Owens, 2009) favor a child-centered (CC) approach involving natural play contexts. This involves introducing activities and objects to which the targeted words can refer and having the clinician provide numerous models of the use of the target words to refer to these objects, activities, and their relations. Choice of target words, again, would be influenced by play assessment. Words chosen on the basis of the child's current knowledge and interests would be included.

Play contexts that give opportunities for incorporating these words into the interaction would allow the client to learn words for ideas already being expressed through play. As in all our CC approaches, clients would not be required to imitate the adult's model in these activities, but would be generously praised if they do.

Hybrid approaches, such as milieu teaching, using either the mand-model or incidental teaching format (see Chapter 3 for details), also can be used to elicit words from the child, and have a strong base in evidence (Hancock & Kaiser, 2006). Milieu teaching, you'll remember, involves organizing the environment so that desired objects and activities must be requested or commented on by clients for them to get the goods and services that they want. Weismer (2000) advocated another hybrid approach, script therapy. In this approach the clinician and child engage in a verbal routine or a ritualized pattern of actions that involves the use of words targeted for the child's early lexicon. At first the clinician does all the talking. If a verbal routine is used, it can be accompanied by a mime or finger play that the child performs. Alternatively, action routines can be used. For example, the clinician can go through a series of steps to place the child's nametag on a board to indicate that he or she is present each day at the intervention session. The clinician can accompany each action in the sequence with a simple utterance (for example, "You're here! Your coat. Take it off. Put the tag on. You put your tag on!"). When the routine is over-learned, the clinician can violate an aspect involving one of the target words. Or the SLP can use a cloze technique, providing the routine language but leaving a blank for the child to fill in the target word ("You put your tag. . . ?"). Whitehurst et al. (1991) have devised a hybrid program for stimulating the early stages of language development that was intended to be used by parents of children with specific language disorders. The methods they suggested for eliciting first words are described in Table 7-9. Lederer (2001) showed that a focused stimulation approach delivered by parents was also effective in increasing overall and target vocabulary acquisition.

It is, of course, also possible to use clinician-directed (CD) approaches, such as drill, drill-play, or CD modeling, with required

imitation to elicit early words. For some clients, this may be an appropriate tack to take. Friedman and Friedman (1980) reported that elicited imitation techniques such as these were more effective with minimally verbal children with low IQs than were more naturalistic approaches, whereas the more naturalistic approaches worked better for children with higher IQs. Connell and Stone (1992) showed that children with specific language impairment were more likely to learn to produce new grammatical morphemes if they were required to imitate during instruction than if modeling alone were used. Kouri (2005) reported that approaches using both CD elicited imitation ("Say, shoe") and hybrid focused stimulation, in which children listened to multiple models of target forms during play interactions without being required to imitate, were equally effective in producing increased use of target words in natural, home settings for toddlers with developmental delays. This suggests that, like older children, toddlers with language delays can benefit from a range of approaches, so long as focused attention on language is present in the activities; whereas CD approaches to early lexical development may be better-suited to the older, developmentally delayed child at an emerging language developmental level. Like all choices about processes of intervention, though, hard and fast rules rarely apply. We need to determine which approach, or mix of approaches, works best for the particular client. Whatever approach is used, the same considerations we have discussed for choosing lexical items should apply. Even in a CD approach, words taught ought to have potential communicative value and appropriate phonological shapes.

Issues concerning receptive language also should be kept in mind when developing a first lexicon. Receptive vocabulary is typically in advance of expression in the emerging language period (Owens, 2009). Children with language impairments in this stage should not be deprived of hearing a rich mix of words, even though we may concentrate on eliciting only a few of them in production. Beyond the specific language elicitation procedures we use with these children, we should encourage parents *not* to limit their word use to the lexical items the child can say (Hart, 2004). Instead we should urge parents to provide a range of labels for objects, events, and relations in clear, here-and-now contexts. If they see that the child is looking at a truck, for example, we should encourage them to label it for him not only as *truck*, but with more specific terms, as well, such as *flatbed*, *cherry-picker*, or *pick-up*. In this way, receptive vocabulary can continue to move ahead even when production is limited.

Developing Word Combinations

Children's first word combinations are used to talk about the semantic relations they already have been encoding with single words (Bloom & Lahey, 1978). As we've seen, most early two-word sentences convey a small range of semantic relations that are common across children and related to their current knowledge and interests, regardless of the language they are learning (Brown, 1973; Grove & Dockrell, 2000). When we try to elicit first two-word utterances, we want to encourage children to talk about these typical early semantic relations. The semantic relations listed in Table 7-7 can serve as a framework.

As with all our language goals, CD, hybrid, and CC approaches can be developed to elicit two-word utterances. CC approaches involve the use of indirect language stimulation. Here the adult engages the child in a play situation. Whenever the child produces a one-word utterance, the clinician expands it to encode the same relation the child intended, using a two-word phrase. For example, if the child were playing with a spoon to feed a doll and said,

"Eat," the clinician might reply, "Yes, the doll eats!" If the child were playing with a car and bumped it into another one, saying, "Bump!" the clinician could remark, "Yes, the cars bump!" or "You bump the cars!" As with all types of ILS, no imitation would be required. The child would be praised for imitating a two-word combination and the clinician could imitate the child's two-word production once again. Our goal would be to provide models of two-word utterances that map ideas the child is already expressing in play. Frome-Loeb and Armstrong (2001) showed that indirect language stimulation techniques aimed at increasing word combinations were effective in eliciting longer utterances from toddlers with language delays.

Hybrid approaches also can be used at this stage. Schwartz, Chapman, Terrell, Prelock, and Rowan's (1985) vertical structuring technique is one example. Here, the clinician responds to a child's incomplete utterance ("doggy") with a contingent question ("Where is the doggy?"). If the child then responds to the question with another fragmentary remark ("bed"), the clinician takes the two pieces produced by the child and expands them into a more complete utterance ("Yes, the doggy is in the bed."). Since this is a hybrid approach, the child is *not* required by the clinician to imitate this expansion. If the client does spontaneously imitate, lavish praise is given. If not, the clinician simply goes on to elicit another set of related utterances from the child and offers the vertically structured expansion again. Enhanced milieu teaching, using incidental teaching techniques to elicit early multiword utterances, has been shown to be effective in eliciting multiword speech (Hancock & Kaiser, 2006), as has conversational recasting (see Chapter 3; Camarata & Nelson, 2006).

Whitehurst et al. (1991) also have developed a hybrid program intended to be used by parents to elicit two-word utterances. This program is an extension of the activities described in Table 7-9 for eliciting single words. The steps in this program are outlined in Table 7-11.

In a script therapy approach (Weismer, 2000), the clinician might teach a finger play, such as "Where is Thumbkin?" After the child has done the finger play with the clinician singing the song numerous times, the clinician might violate it by singing, "What is Thumbkin?" or by holding up one of the fingers ("pinky" is probably easiest to pronounce) and delaying the production of the line in the song. If the child corrects the clinician ("No! Where pinky?") or produces an appropriate two-word utterance when the clinician delays ("Where pinky?"), lavish praise can be used as a reward, and additional violations or delays can be used later. If the child does not correct or fill in, the clinician can continue to provide the language routines and try again another time. Focused stimulation is another hybrid technique that has demonstrated efficacy in eliciting both early words and word combinations (Bunce, 1995; Kouri, 2005; Weismer & Robinson, 2006; Wilcox & Shannon, 1998).

CD approaches also have been used to elicit early two-word utterances. Leonard's (1975a) modeling procedure has been used successfully. As you'll recall from Chapter 3, Leonard's (1975a) method involves a confederate of the clinician's, such as a parent or puppet, who is used as a model. The clinician, after pre-testing the client on the target structure, gives the model a set of pictures not used in the pretest and asks the confederate to "Tell what's happening here." The confederate provides a two-word utterance that describes each picture presented by the clinician (e.g., "boy drink," "girl eat," "cat walk"). After 10 or 20 of these descriptions, the client is asked to "talk like" the model and to

TABLE 7-11 Suggestions for a Parent-Administered Program of Early Language Intervention: Word Combinations

Biweekly Assignment	Activity
1	Introduce word combinations: Begin to require child to produce two-word versions of requests used in earlier activities. Reward with verbal praise ("Good talking!").
2	Shift reward from verbal to social: Have the child label objects and activities in which the reward is attention and praise, rather than receipt of the object or activity.
3	Storybook reading: Parent asks the child to label pictures during book reading. Parent responds to child's label with a <i>wh</i> -question ("What does the cow say?").
4	Open-ended questions: Parent uses open-ended prompts during storybook reading ("Tell me about this page."). Parent is taught to expand on child's remarks.

Adapted from Whitehurst, G., Fishel, J., Lonigan, C., Valdez-Menchaca, M., Arnold, D., & Smith, M. (1991). Treatment of early expressive language delay: If, when, and how. *Topics in Language Disorders, 11*, 55-68.

describe a similar but not identical set of pictures. The model and client alternate their productions until the child produces three consecutive correct versions. Then the child is asked to continue until a criterion (say, of 10 consecutive correct responses) is reached. At this point the pretest stimuli would be post-tested without models.

MacDonald et al. (1974) developed the Environmental Language Intervention Strategy (ELI), which is summarized in Box 7-6. This is a CD approach that has some naturalistic modification in that it involves some extensions into semi-controlled versions of conversation and play. Parents are taught to work on the same language goal, usually a particular semantic relation, for 15 minutes in each of the three conditions—imitation, conversation, and play. Sessions take place three times a week in the child's home. The SLP visits the family monthly in a consultant capacity to review progress and make any changes necessary in the child's program. As semantic relations are added to the child's repertoire, new ones are introduced into the intervention program.

One issue that commonly comes up when we attempt to elicit early two-word utterances is whether the linguistic input should be well-formed or contain the deletions that children are likely to make in these utterances, resulting in telegraphic productions. In other words, we need to decide whether we will say, "Pat bunny," or "Pat the bunny." We discussed this issue in Chapter 3, but let us reiterate our position here. Although Van Kleeck et al. (2010) were not able to find definitive evidence that telegraphic or grammatical input made a difference to children with emerging language, Fey, Long, and Finestack (2003) and Leonard (1995) have argued that the sentences children hear should contain all the required grammatical elements, even if we expect that the child will delete them in his or her own production. And Kouri (2005) showed that reduced models were not more effective than grammatical models in eliciting longer utterances from toddlers with delayed language. It may be that hearing a full sentence can help the child to build up an accurate auditory image of what well-formed sentences are supposed to sound like. Leonard (1995) suggests that it helps to focus on the weak-strong syllable pattern that is prevalent in English and appears to facilitate children's identification of important units in the speech stream. The rhythmic frame of the utterance that is created by the inclusion of grammatical morphemes may eventually help the child to fill in the slots created by the rhythm. If the child does not comprehend the morphemes and inflections, Chapman

BOX 7-6 Three Phases of the Environmental Learning Intervention Strategy

PHASE ONE: IMITATION

A linguistic and nonlinguistic stimulus are paired. The child is told to imitate the adult; e.g., the adult pets a stuffed animal and says, "Pet the bunny. You say it: 'Pet the bunny.'"

If the child responds correctly, the adult repeats the child's utterance, gives praise and a token reinforcement (e.g., "Pet the bunny. Good talking!" and presents a plastic chip).

If the child fails to respond or responds incorrectly, the adult looks away for 3 seconds, then repeats the stimuli.

PHASE TWO: CONVERSATION

The nonlinguistic stimuli are the same as in the imitation phase.

The linguistic stimulus is a question, rather than a request for imitation (e.g., "What am I doing?").

Response to correct productions is the same as in the imitation phase.

If the child fails to respond or responds incorrectly, an imitative prompt is given, followed by a repetition of the linguistic

stimulus (e.g., "Say 'Pet the bunny.' What am I doing?"). This may be repeated.

PHASE THREE: PLAY

While the child is playing with the materials used as nonlinguistic stimuli in the imitation and conversation phases, the adult asks for the conversational response in an appropriate context (e.g., if the child pets the toy bunny, the adult can ask, "What are you doing?" Or the adult can pick up one of the toys and ask, "What shall I do?").

If the child gives a correct response containing a two-word expression of the target semantic relation, a confirming response is given (e.g., "Yeah, you pet the bunny!").

If the child does not respond or responds incorrectly, the adult does not confirm the response or comply with the request. Instead, a 3-second pause is followed by a request for an imitation of the target utterance.

(1981) argued that they will simply be filtered out by the child's comprehension strategies and so will not get in the way of understanding the message. Well-formed, grammatical input cannot do any harm, and it may do the young child some good. It also is a more naturalistic form of input, and parents who are involved in delivering intervention will probably feel more comfortable speaking to their child "correctly." As always, the decision as to the method of intervention, whether it is CD, CC, hybrid, or some combination of the three, will be based on the needs of the individual client. But whatever approach we use, we would argue that the linguistic input ought to be complete and well-formed.

Preliteracy Development

It may seem early to be thinking about literacy, but the emerging language period is a time in which typically developing toddlers are acquiring important experiences with books and print (Dodici, Draper, & Peterson, 2003). Bernadowski (2008), Machado (2010), Rosenquest (2002) and Scheffell and Ingrisano (2000) described ways to use storybooks in working with toddlers and their families in order to build early language and literacy skills:

- Working collaboratively to select books that are developmentally appropriate and attractive to toddlers and being sure families have access to these books
- Teaching parents routine interactive reading strategies, such as pointing out connections between pictures and text, stopping to let children "fill in" elements after they have heard the story a few times, etc.
- Encouraging parents to use exaggerated intonation and stress during reading to highlight important elements in the text
- Encouraging parents to develop play activities around the themes from storybooks read; e.g., after reading *One Fish, Two Fish*, children can be encouraged to find red and blue things in their house
- Exposing children to decontextualized talk relating the stories they have heard to their own day-to-day activities; e.g., talking about times the child has seen fish

Zeece and Churchill (2001) discussed additional strategies for choosing and using books with toddlers. For SLPs, preliteracy development at the emerging language stage will consist primarily of encouraging families to expose their children to interactive storybook reading, and helping parents develop book sharing strategies that fit

in with their parenting style and schedule. Trivette, Dunst and Gorman (2010) reviewed literature that showed having parents read to children increases receptive and expressive language. They found the most effective characteristics to be those that encouraged children's engagement and active participation in shared reading experiences. We know that children with disabilities tend to have less exposure to books during their early years than typically developing children do (Goin, Nordquist, & Twardosz, 2004), so anything we can do to enhance toddlers' opportunities to get experiences with literate language and literacy artifacts will be helpful.

TODDLERS WITH ASD

Until recently children with ASD were rarely diagnosed before the age of 3 (Fombonne, 2005), but current research suggests that the clinical diagnosis of autism can be reliably assigned in the second year of life, and is stable when conferred by a multidisciplinary team of experienced clinicians (Chawarska et al., 2009). Since impairment in communication is one of the core symptoms of this syndrome, SLPs who work in early intervention will have toddlers who have received a diagnosis of ASD on our caseloads, and we will be expected to develop and implement programs to improve their communication and language. Although many of the assessment and intervention topics we have discussed for children in the emerging language phase will apply to toddlers with ASD, as well, there are a few special considerations we will want to apply for this population. Let's take a look at what these are.

Assessment Considerations for Toddlers with ASD

Screening

Several screening measures have been developed specifically to identify toddlers with ASD. In fact, the American Academy of Pediatrics recommends that pediatricians routinely screen for ASD with instruments like these during the second year of life. SLPs who work in early intervention settings may advocate for these early screening efforts. Box 7-7 contains some examples of instruments designed to screen for ASD in toddlers. Children who fail these screeners will need to be evaluated to determine whether ASD is present.

Evaluating Communication

In addition to using screeners like these, SLPs also need to be aware of the symptoms of ASD that tend to predominate in toddlers. Box 7-8 summarizes the communication deficits most often seen in 18- to 36-month-olds with ASD. Paul (2008b) suggested that assessment focus most sharply on these areas where problems are likely to be seen. Standard measures of expressive and receptive language, like those listed in Appendix 7-1 can be used to document delay in language, but additional measures will be needed to describe the areas of difficulty seen in Box 7-8. Intentional communication is likely to be impaired; assessments we discussed for this area, including the *Communication and Symbolic Behavior Scales—Developmental Profile* (CSBS; Wetherby & Prizant, 2003), the *Prelinguistic Communication Assessment* (Stone et al., 1997), and *Communicative Intention Inventory* (see Figure 7-2) can be used to document restrictions in frequency, form, and functions of communication. Play and gesture are also likely to be impaired. The CSBS has Play and Gesture scales, and the instruments

Preliteracy development for children with emerging language means encouraging families to help their toddlers learn to enjoy books and reading.

BOX 7-8 Communication Deficits in Toddlers with ASD

Delayed acquisition of spoken language.

Depressed rate of preverbal communicative acts.

Delayed development of pointing gestures, both in terms of use and responsiveness.

Use of nonconventional means of communicating, such as pulling a person by the hand, instead of pointing or looking.

Reduced responsiveness to speech and to hearing their names called, resulting in lower scores on comprehension than production.

Restricted range of communicative behaviors, limited primarily to regulatory functions (getting people to do or not do things), with very limited use of communication for social interaction or to comment or establish joint attention.

Atypical preverbal vocalizations.

Deficits in pretend and imaginative play.

Limited ability to imitate.

Cohen (Eds.), *Handbook of Autism and Pervasive Developmental Disorders* (3rd ed., Vol. 1, pp. 223-246). New York: Wiley; Paul, R. (2008). Communication development and assessment. In K. Chawarska, A. Klin, & F. Volkmar (Eds.), (pp. 77-103) *Autism Spectrum Disorders in infants and toddlers*. New York: Guilford Press.

we have already discussed for assessing play and gesture can also be used.

Diagnostic Assessment

Bishop, Luyster, Richler, and Lord (2008) advocate the need for a multidimensional, multidisciplinary assessment to diagnose ASD in toddlers. Figure 7-6 provides an outline of their recommendations. Several instruments have been designed specifically to assist in diagnostic assessment for this population. Standardized parent interviews have been developed to probe for information regarding autism-specific behaviors. The most widely used is the *Autism Diagnostic Interview-Revised* (ADI-R; Lord, Rutter, & LeCouteur, 1994); however its validity for children under 3 is not yet fully established. The *Diagnostic Interview for Social Communication Disorders* (DISCO; Leekam, Libby, Wing, Gould, & Taylor, 2002) has similar shortcomings.

Bishop et al. (2008) also recommend direct observation of behaviors characteristic of ASD. Measures designed to provide “presses,” or temptations for the display of these behaviors, such

as difficulty in imitation, play, joint attention, and gaze include The *Autism Diagnostic Observation Scale-Module 1* (ADOS; Lord et al., 2000). This measure assesses communication, social and repetitive behaviors in children with prelinguistic and emerging language function. The *Autism Observation Scale for Infants* (AOSI; Bryson et al., 2008) is designed to elicit a similar set of behaviors. The administration and interpretation of these measures requires specialized training, but this training is very valuable for identifying autism specific behaviors in young children and is worthwhile for SLPs who see many children with ASD in their practice. ADOS training is available through Western Psychological Services. (http://portal.wpspublish.com/portal/page?_pageid=53,80783&_dad=portal&_schema=PORTAL)

Intervention for Toddlers with ASD

As we discussed in Chapter 6, the primary role for SLPs working with toddlers with ASD who remain in the prelinguistic phase of development (as many with this disorder will) is to establish the foundational skills for language learning—imitation, prelinguistic communication, and play skills—to enhance language comprehension, which is usually impaired in this population (Hudry et al., 2010), and to work toward the acquisition of spoken language. For children with no speech who are showing communicative intent, Signs and other AAC approaches may be presented as a bridge to speech, but vocal imitation and speech production should also be a focus of intervention for these children. More detailed discussion of intervention for prelinguistic children with ASD can be found in Chapter 6.

Toddlers with AAC who are in the emerging language stage will be those who use some words, many of whom display immediate or delayed echolalia. Here our primary intervention goals will be to, again, enhance attention to speech and receptive language ability, to increase spontaneous spoken vocabulary and utterance length, and to work with echolalia (not extinguish it) to increase its functionality.

Receptive Language

Little research has been directed to increasing receptive language in toddlers with ASD, but work by Adamson, Bakeman, Deckner, & Ronski (2009) indicates that symbol infused joint attention; that is, the amount of time spent attending to a shared object that the communication partner is naming and talking about; is related to the growth of receptive (as well as expressive) language. This suggests that working toward increased understanding of language would include

- providing highly engaging joint attentional opportunities, by
 - sharing interesting objects and activities with the client
 - actively attracting their attention and gaze to the object and to the communication partner
 - providing simple, repetitive language to accompany the activity

Kasari et al. (2008) provide detailed discussion of joint attention intervention for this population. Taylor and Hoch (2008) used applied behavior analytic approach, in which an instructor walked the child toward a preferred item and waited 5 seconds for the child to initiate a comment on the item. If the child did not, the instructor used physical and gestural prompts to point to the item and provided an echoic prompt to make a comment about the item (“Say, ‘Look!’”). They were able to show increases in proto-declaratives in children with ASD using this method.

FIGURE 7-6 Bishop et al.'s (2008) recommendations for multidisciplinary diagnostic assessment of ASD in toddlers. (Modified from Bishop, S., Luyster, R., Richler, J., and Lord, C. [2008]. Diagnostic assessment. In Chawarska, K., Klin, A., and Volkmar, F. R. [eds]: *Autism Spectrum Disorders in Infants and Toddlers: Diagnosis, Assessment, and Treatment* [pp. 23-49]. New York, 2008, Guilford Press.)

Work by Preissler (2008), in which she found that when taught names of pictures, children with ASD did not recognize the real objects the pictures represented as having the same label as the picture, suggests that children with ASD have difficulty understanding that pictures are representations of objects. This means that it is important to teach receptive language in relation to real, functional objects rather than pictures with this population.

Vocabulary and Utterance Length

Several approaches have shown promise for increasing expressive vocabulary in young children with ASD. McDuffie, Yoder, and Stone (2006) showed that the techniques used in milieu teaching—such as following the child's attentional lead, labeling objects the child shows interest in, withholding objects in which they child shows interest and using expectant waiting—were associated with increases in spoken vocabulary in children with ASD, and they seem to be effective when presented by both clinicians and parents (McDuffie and Yoder, 2010). Discreet trial methods have also shown efficacy (Prelock et al., 2011), but again, it must be remembered that real objects rather than pictures should be used, and the approach should be supplemented with naturalistic opportunities to use new words learned.

Several applied behavior analysis (ABA) programs have been specifically designed to increase expressive language in children on the autism spectrum. These include *Teach Me Language* (Freeman & Dake, 1997), *Verbal Behavior* (Partington & Sundberg, 1998), and *The "Me" Book* (Lovaas et al., 1980). Reichow and Wolery (2009) reported that these approaches are moderately successful in guiding children with ASD from single words to longer utterances, although as Smith (2001) advised, they should always be supplemented by more functional, naturalistic activities. McClannahan

and Krantz (2005) provide a manual for using script therapy to increase productive language in children with ASD. Their research demonstrates that this approach is especially effective when scripts are first learned, then gradually faded, by removing small parts of the script with each successive practice. McClannahan and Krantz's book provides detailed instructions for using script therapy for children with ASD from prelinguistic to advanced language levels.

Working with Echolalia

When children with ASD start talking, they often begin by imitating what others say, either just after they say it (immediate echolalia), or as a "script" they repeat later (delayed echolalia). Often this talk appears self-directed and is not used for communicative purposes, but it is sometimes used to serve a range of functions (Prizant & Duchan, 1981; Stribling, Rae, & Dickerson, 2007), which are summarized in Table 7-12. Echolalia usually decreases spontaneously as expressive language skill increases (Tager-Flusberg et al., 2005), but part of our role with children at this phase is to push this decrease along. Several approaches to help reduce echolalia include:

- *Using a third person (or puppet) to model what should be said.* For example, to get a child to use language to make a request, instead of prompting, "say _____," demonstrate what happens when the puppet makes an appropriate request (says "I want juice, please" and gets juice), then encourage use of this model. This activity can be turned into a turn taking game, in which the puppet makes a statement and the child imitates it in order to accomplish what the puppet did (make a request, get another piece of a puzzle, etc.). In this way functional models can be given that demonstrate how to use language to accomplish social goals.

TABLE 7-12 Some Communicative Functions of Echolalia

Function	Description and Example
Turn-taking	Adult: How was your weekend? Client: Weekend.
Verbal completion	<i>Completes a familiar routine initiated by an adult.</i> Adult: What do you do first? Client: Hang up coat (echoed from adult's completion of routine on previous occasions).
Declaration	<i>Labels using an echo.</i> Adult: What kind of ice cream do you have? Client: Ice cream.
"Yes" answer	Adult: Do you want a cookie? Client: Cookie.
Request	Adult: There's a car in the toy garage here. Client: Car in garage (used with gesture toward car).
Protest	<i>Delayed echolalic remark used to protest or prohibit others' action.</i> Adult: Let's do our speech work now. Client: Don't you dare! (echoing remark parent made earlier).
Directive	<i>Delayed echolalia used to direct others' actions.</i> Client: Time to clean up now (echoed from teacher's previous remark; used to tell fellow student to pick up blocks).
Calling	<i>Delayed echolalia used to get attention.</i> Client: All eyes up here (echoed from teacher's use of same phrase; used to get peer to pay attention to client during play interaction).
Provide information	<i>Delayed echolalia used to give new information not in the immediate environment.</i> Client: Dog's loose again (echoed from parents' use of same remark; used to inform teacher that something anxiety-producing has happened).

Adapted from Prizant, B., & Rydell, P. (1984). Analysis of functions of delayed echolalia in autistic children. *Journal of Speech and Hearing Research*, 27, 183-192; Stribling, P., Rae, J., & Dickerson, P. (2007). Two forms of spoken repetition in a girl with autism. *International Journal of Language & Communication Disorders*, 42(4), 427-444.

- *Mitigated echolalia.* When an echoed utterance is produced, the clinician can echo it back, then ring a slight change and invite imitation of the change. For example, if the child says, "yellow balloon," the clinician can say "Yellow balloon! I like blue! Blue balloon!" Available materials that correspond to the modified model can be offered and withheld until the mitigated form is produced. Once this can be done in short phrases, longer utterances can be used. When the child is able to make changes fairly quickly, the changes can be made more extensive. Instead of changing one word, the clinician can change a whole phrase within an utterance (Child: "I wanna play bubbles"; Teacher: "You do? I wanna clap hands!"). The same kinds of activities can take place around the social routines being learned. If learning to sing "Five Little Monkeys," for example, the routine can be changed to "Five Little Doggies," etc.
- *Adapting scripts.* Using McClannahan and Krantz's script therapy approach, starting with scripts the child already echoes, and changing small parts of the script to more adaptive, other-directed speech. For example, if the child likes to recite a script from Thomas the Tank Engine, the clinician can start by changing the names and actions in the script to names of people in the child's family and things they normally do, and encouraging the child to imitate these changes, using a script fading procedure.

It is important to remember that, as we work on decreasing echolalia, we want at the same time to work on increasing vocabulary and sentence length, since children with ASD typically decrease their echoed speech as their spontaneous language grows.

CONSIDERATIONS FOR OLDER CLIENTS IN THE EMERGING LANGUAGE STAGE

Some children with severe disabilities remain in the emerging language stage for an extended period. Children with severe intellectual disability, those with autism, and children who suffer severe effects of acquired neurological damage are examples of clients who may present this picture. Many of these children have feeding and swallowing problems; these can be addressed with all the techniques and resources we discussed in Chapter 6. Older clients at this stage of development have some rudimentary form of symbolic communication but have not progressed beyond the one- or two-word (or symbol) stage in their expression of communicative intents. Our responsibilities with these clients are threefold: to maximize the effectiveness of the emerging communicative forms they express, to provide opportunities for them to expand the sophistication of their communication to as great an extent as possible, and to work on expanding the opportunities for and responsiveness to their communication by people in their environment.

Modifying Assessments for Older Clients with Emerging Language

When assessing communication skills in the older client with emerging language, we address the same issues we talked about for children at this stage with mild to moderate disabilities: play and symbolic skills; intentional communicative abilities; comprehension; and expressive capacities in the areas of phonology, vocabulary, and word combinations. When speech is not an option for

these clients, the viability of augmentative and alternative forms of expression also need to be explored. We may have to modify some of our assessment procedures to gain the information we need, though. Let's take a look at how this might be done.

Play and Gesture

The first point to remember in developing play and symbolic assessments for children in the emerging language stage is that the purpose of these evaluations is *not* to determine whether the child has the "prerequisites" for a communication system. Instead, we use this information to help us decide how best to implement communication intervention for these clients. When we evaluate children with motor impairments, they may have trouble demonstrating the symbolic behaviors we usually look for, such as use of objects for pretend or the use of conventional gestures. If this is the case, we may need to turn to other types of nonverbal assessment that can be demonstrated without so much motor involvement. Object permanence skills are one example of cognitive skill that can be demonstrated with eye pointing. Some assessment of object permanence ability, using methods such as those outlined in Dunst (1980), might serve as an index of cognitive skill in severely motorically involved clients. Traditional Piagetian assessments also can be modified by the clinician. For example, we can supply the child with a Velcro mitt to allow him to use a support (pillow or cloth) to obtain a toy out of reach, or attach string toys to switches to allow the child to operate the switch in order to use the string to obtain the toy. Guerette, Tefft, Furumasa, and Moy (1999) have validated a cognitive assessment battery for use with individuals with physical disabilities. Robinson, Bataillon, Fieber, Jackson, and Rasmussen (1985) have developed a parent-interview form to assess sensorimotor skills in children with physical disabilities. These procedures can be helpful in making an estimate of symbolic ability in children with severe speech-motor impairments. In addition, Byrne et al. (2001) reported on the development of new tools that measure brain activity during tasks such as looking at sets of pictures that do and do not match. These emerging protocols do not require either verbal or motor responses; they may be helpful in the future for getting a more accurate picture of the cognitive function of children with severe motor disorders.

Intentional Communication

In assessing intentional communication skills in older clients with emerging language, we want to look at *all* expressions of intent, including nonconventional and maladaptive forms. For clients without functional speech, it is especially important to assess the use of other communicative signals, such as gestures, sounds, limb actions, facial expressions, body postures, and orientation. We need to know what and how the client is attempting to communicate in order to provide more mature means for expressing these intentions that are already present. When we observe maladaptive behavior in these clients, it is especially important to attempt to identify the communicative intent of these behaviors. Rather than ignoring or extinguishing them, we may want to attempt to shape them into more conventional forms. It is important to observe the client in natural settings, such as the home or classroom, to see when these behaviors occur, what precedes them, and how adults in the environment react to them. These observations help us understand what intents the client is communicating by the behavior, what environmental events trigger the behavior, how the contingencies the client receives as a result of the behaviors tend to reinforce rather than reduce them, and the degree to which

breakdowns in communication contribute to maladaptive behavior (Halle, Brady, & Drasgow, 2004). With this information we can work to give the client conventional ways to express the intents once we understand them. In addition, we can work toward modifying the environment so that acceptable behavior is reinforced while maladaptive behavior is not.

Halle et al. (2004) remind us that we need to use both naturalistic observations and structured probes in assessing the communication of AAC users. Naturalistic observations can show us how often communication occurs, how it is responded to, when breakdowns occur, and their relations to maladaptive behavior. This kind of functional assessment is crucial to understanding the communicative needs of clients with emerging language. But it may take a long time to gather all the information we need if we wait for it to happen naturally. That's why we can also learn a lot by using structured communication temptations to elicit particular kinds of communicative acts. For example, if we want to know how a child will clarify a message if it is misunderstood, we can offer the child two objects, see which one he or she chooses, then pretend to misunderstand and give the wrong one. This probe elicits the child's strategies for clarifying communication without having to wait until a natural misunderstanding occurs.

Comprehension

When we assess comprehension skills in older clients with emerging language, we may again be faced with motor impairments that limit a child's ability to respond. If a child cannot point, we can have the client use eye pointing for picture or object identification. Eye-pointing behavior may need to be taught explicitly during the assessment session to maximize its use. Yes/no responses are another alternative to pointing or object manipulation for assessing comprehension. Instead of asking a child, for example, to "Show me, 'The horse pushes the truck,'" we might demonstrate a toy truck pushing a toy horse, and ask "Is the horse pushing the truck?" Any *yes* or *no* response the child has available (head nod, sign, pointing, or eye pointing to a yes or no signal on a communication board) can be accepted. Miller and Paul (1995) provided additional suggestions for modifying informal comprehension assessments for children with a variety of disabilities.

We need to be careful in using pictures for assessing comprehension in clients at this level. As Glennen (1997) discussed, we should not assume that children understand that a picture is a representation of a referent. Before using pictures to test language comprehension, we need to pretest the child's ability to associate pictures with their referents. This can be accomplished by pretesting the child's ability to identify line drawings of common objects with which we know the child is familiar. If the child is unable to do this, Glennen suggests trying the same task with color photographs. If the child is still unable to associate common objects with their photographic representations, we may need to use objects themselves in the comprehension assessment. We also should remember that children with severe impairments might have more difficulties than younger, less impaired children in choosing from an array of several items or pictures. If a child has difficulty in selecting a named object from an array of four pictures, for example, we may try reducing the array to a choice between just two.

Phonological and Lexical Production

Looking at productive skills in older clients with emerging language should include examining both phonological and lexical skills. Reports have appeared in the literature of nonspeaking adolescents

who have developed speech skills (Pickett, Pullara, O'Grady, & Gordon, 2009; Ronski & Sevcik, 1996; Windsor, Doyle, & Siegel, 1994), so speech need not be eliminated as a goal, even if a client with emerging language currently uses some AAC system to communicate. Ongoing assessment of phonological production can help identify whether speech will become a possibility for some of these clients. Periodically assessing spontaneous vocalizations for phonetic inventory and syllable structure level can be part of the ongoing evaluation plan for older clients with emerging language. When new sounds or syllable shapes appear in the repertoire, they can be incorporated into speech targets, using facilitating contexts like those outlined in Box 6-7. If an AAC system is already in use, it need not be abandoned. Some clients may be able to produce some communication by means of speech and continue to use the AAC system for the remainder of their communication. Adding some speech to the repertoire of these clients or increasing the amount of speech they produce can expand their communicative range and make their AAC system even more efficient.

To assess lexical knowledge in these older clients with emerging language, the parent checklists we discussed earlier can be very beneficial. The *MacArthur-Bates Communicative Development Inventories* (Fenson et al., 2007) are especially helpful because they contain scales that address symbolic play, words produced, words understood, and word combinations produced. Detailed information in this broad range of areas obtained from parents with intimate knowledge of their child's abilities can provide a very useful picture of the client's skills. The *Vineland Adaptive Behavior Scale II* (Sparrow, Cicchetti, & Balla, 2005) is another parent-report instrument that can be very effective for clients at this developmental level. It has excellent psychometric properties and gives an in-depth picture of adaptive uses of both receptive and expressive communication.

Motor Skills Assessment

For clients with severe speech and physical impairments, the choice of an AAC system is strongly dependent on the physical abilities of the client to manipulate the aspects of the system. Signs may be a viable system for children with relatively good motor skills, but if a child's Signs are as unintelligible as his or her speech, another form will have to be investigated. Although this complex issue cannot be explored in detail here, DeCoste (1997) and Sevcik, Barton-Hulsey, & Ronski (2008) discussed these issues, emphasizing that the goal of this assessment is *not* to identify motor deficits but rather to discover motor capabilities that *can* be used to access a system. This assessment involves examination of the following five major components:

Movement: Here we try to find the client's best movement pattern; one that is reliable and accurate and can be performed without undue effort and minimal abnormalities of tone and overflow movement. Finger, hand, arm, and head movements are used most often. Chin, mouth, and shoulder movements are used if these others are not available. Lower extremity movements are used as a last resort. Emerging technologies also use eye blink and eye movement. This evaluation is best conducted in collaboration with other professionals, such as occupational and physical therapists, who can assist with the motoric assessment, as well as with teachers and family members who need to facilitate the client's use of the system in everyday settings.

Control site: This refers to the point of contact with the communication device. It may be a body part, such as a fingertip or hand, or an aid, such as headstick or light beam from a laser pointer.

Input method: The communication aid itself provides a method by which the client inputs intentions to communicate. It may be a computer keyboard, touch window, or cardboard with pictures or symbols on it. The device also may include some type of switch or joystick by which the client indicates a selection. Input can take place by means of *direct selection*, where the client indicates directly (by pointing, touching, or using a headstick or laser beam) what he or she wants to choose. If direct selection is not possible because of movement limitations, *scanning* may be used. Here the device goes through a series of choices and, when the one the client wants is indicated, he or she hits a switch to indicate a choice.

Positioning: The optimal placement of the communication device needs to be considered in light of the client's movement abilities, choice of control site, and input method. This often involves trial and error to determine the best arrangement of the device and switching equipment.

Targeting: The number, size, position, and spacing of symbols on the communication array needs to be assessed in order to maximize its accuracy and reliability for the client.

Beukelman and Mirenda (2005); Bridges et al. (1999); DeCoste (1997); and Lloyd, Fuller, and Arvidson (1997) provide detailed guidance for doing this assessment. McNaughton and Beukelman (2010) discuss the issues for adolescents who use AAC as they transition out of school settings.

Intervention Targets and Procedures for Older Clients with Emerging Language

Play and Gesture

It's important to foster symbolic ability in older clients with emerging language. The nice part about this obligation is that it encourages us to engage these clients in play. Because we want to adhere to the principle of using chronologically age-appropriate activities for these older students, the kinds of play we set up will be different from the pretend situations with dolls and toys that we use for children closer to the normal chronological age range for emerging language. Nelson (1998) suggested using practical jokes as play activities with older clients with emerging language. A clinician can model placing a rubber slug on her shoulder and can collude with clients to see how it affects another teacher in the room. Students can then be allowed to communicate requests to play similar tricks on each other and other staff members. Using vocational and daily living props for unconventional, silly uses is another way to encourage play. A clinician might, for example, conclude a lesson on making pudding by putting the mixing bowl on her head (after the designated dishwasher has done his job!) and commenting, "Nice hat!" Students also can be allowed to play similar tricks with other materials they use in group activities, so long as they frame their silliness as a "joke" by producing a comment about it. Similarly, we want to encourage gestures in children who have the motor ability to produce them. Accompanying our own speech with gestures, using the hierarchy in Table 7-3 can encourage children to incorporate gestures into their communicative repertoires.

Intentional Communication

Regardless of the form of a client's communication, whether it be speech, Sign, or some other AAC system, most clients with emerging language need to increase the frequency of their communicative acts. Many also need to expand the range of intentions they

express. When these needs are evident from the assessment, communication temptations will again be a useful technique. As with other methods for older clients, we want to adapt these temptations to make use of age-appropriate materials. Instead of a wind-up toy, for example, we might turn a radio or MP3 player on to favorite music for a moment, then turn it off and wait for a request to turn it on again. Instead of blowing bubbles, then closing the jar lid tightly, we might put a favorite item in a clear glass jar, close the lid tightly, and hand the jar to the client, waiting for a request for help to open the jar. The practical jokes and tricks we talked about in our discussion of play skills also can be very useful contexts for developing joint attentional and commenting behavior.

For clients using or being introduced to AAC systems, we want to expand the frequency and range of communications expressed by means of the AAC modality. Here we may use prompt-free approaches, such as the ones discussed in Chapter 6, to shape behavior into communication and continually up the ante to require more conventional forms of expression. We can reward a random touch to a picture of an MP3 player on a client's communication board by turning on the device for a moment. Later we can require more purposeful pointing or eye pointing before we turn on the music. Still later, we can up the ante to requiring a point at the picture on the communication board and a glance at the clinician.

In addition, we need to find ways to increase the effectiveness of our students' communicative acts. Halle et al. (2004) discuss the role of *functional communication training* (FCT) in providing this kind of support to students with emerging language. FCT goes beyond simply teaching students to express needs; it is aimed at providing strategies for a range of situations in which communication can serve to reduce problem behavior and support integration. FCT involves identifying the purpose of maladaptive behavior, finding out what triggers it, and providing the student with new, more adaptive ways to solve the problems with which they are confronted. Sigagfoos et al. (2004), for example, discussed ways of teaching students with emerging language how to reject objects and activities in a socially acceptable and effective way. These are summarized in Box 7-9. Halle et al. (2004) discuss specific techniques to teach for repairing communicative breakdowns. Ruppert et al. (2009) showed that these interventions tended to result in changes that were maintained even after the intervention was stopped. We will discuss FCT in more detail in Chapter 9.

Comprehension

Encouraging the development of language comprehension in older clients with emerging language involves many of the ILS techniques we discussed in Chapter 3 (expansions, extensions, build-ups and breakdowns, recasts, parallel talk, and self-talk). Cross (1984) suggested further that parents of children with disabilities should be encouraged to make their remarks closely tied in meaning to those of the client, to reduce their directiveness and increase their responsiveness, to speak slowly and clearly, and to talk with their children as often as possible. These activities are helpful to any client in the emerging language stage, regardless of age. For older clients with severe impairments, though, it is especially important to remember that we also want to provide models of talk about objects and events outside the "here and now." Lucariello (1990) referred to these kinds of topics as *displaced talk*. They are crucial for showing clients how language is used to go beyond the immediate context to provide new information. First steps in this direction can include talk about familiar, highly "scripted" events that happened in the recent past (for example, talking about what a

BOX 7-9 Steps to Teaching Communicative Rejection

1. Identify behaviors used to avoid or escape events.
2. If behavior is unacceptable, inefficient or hard to interpret, replace old form with newer, more efficient and acceptable form.
3. Define new replacement behavior in objective, measurable terms; e.g., "when presented with an unwanted object, student will select the 'don't want' symbol on communication board within 15 seconds."
4. Ensure new form is efficient by making sure the new form is easy to perform and leads to consistent reinforcement. Be sure everyone who interacts with the student knows this.
5. Provide instruction in new form when student is highly motivated to reject. Use incidental teaching techniques to provide extra practice.
6. Create extra opportunities for practice by offering objects or activities, and giving the nonpreferred choice, even when student requests the other.
7. At first use prompts to elicit the new behavior; provide immediate and consistent reinforcement for new behavior, no reinforcement for maladaptive behavior. Gradually fade prompts.
8. Be sure the new behavior is always rewarded with stopping the unwanted object or activity consistently by all who interact with the student.

Adapted from Sigagfoos, J., Drasgow, E., Reichle, J., O'Reilly, M., Green, V., & Tait, K. (2004). Tutorial: Teaching communicative rejecting to children with severe disabilities. *American Journal of Speech-Language Pathology*, 13, 31-42.

client had for breakfast when he arrives at school) or will happen in the near future (for example, talking just before a client leaves school in the afternoon about what will happen at dinner time). Parents, too, should be encouraged to engage in these kinds of simple "there-and-then" displaced talk activities around events with which the client is familiar.

Harris and Riechle (2004) showed that aided language stimulation is especially effective in increasing language comprehension and production in this population. Aided language stimulation involves the adult using both speech and the child's augmentative system when directing input to the child. For example, if an adult is telling a child who uses a picture communication board to eat his cereal, the adult would not only say, "Eat your cereal," but would simultaneously point to the appropriate picture(s) in the child's communication book. Providing this enriched input appears to encourage children not only to learn the meaning of their augmentative symbols, but to use them more frequently, as well.

Production

One of the crucial decisions to be made for children with severe impairments concerns is whether to focus on an AAC system for expression or to provide structured speech training. Yoder, Warren, and McCathren (1998) showed that speech development is significantly related to the child's number of consonant-vowel (CV) vocalizations in a 15-minute communication sample (more than one CV production per four minutes predicted the development of functional speech 1 year after the assessment); the rate of proto-declaratives produced (more than one comment per five minutes

predicted functional speech); and the receptive-to-expressive vocabulary ratio, as assessed by parent report on Fenson et al.'s (2007) *Communicative Development Inventory* (more than four words said for every 100 understood predicted functional speech). These findings can be helpful in differentiating which children have the highest likelihood of developing speech skills from those for whom AAC should be the main focus of intervention. Millar, Light, and Schlosser (2006) report in a meta-analysis that, although nonverbal children supplied with AAC systems made only small gains in spoken language production, none of the cases studied demonstrated decreases in use of speech, so AAC does not appear to impede speech production, although it should not, on its own, be expected to lead to large changes in spoken language ability. Still the power to communicate, even in a nonspeaking modality, is an important end in itself for nonverbal clients.

The means of deciding what AAC modality will be most effective to facilitate communication in clients at emerging language

Clients in the emerging language stage can use AAC devices to produce their first expressive language forms.

Communication programs implemented on standard consumer electronic devices are less stigmatizing and enhance interactive opportunities.

levels is, again, too complex an issue to discuss in detail here. Beukelman and Mirenda (2005), Bridges et al. (1999), Millikin (1997), and von Tetzchner and Grove (2003) provided detailed discussions of the considerations that go into making this decision. Light and Drager (2007) and Ronski et al. (2010) discuss AAC issues that pertain particularly to young children. For starters, though, there are a few rules of thumb we can use to guide us.

For clients with severe speech and physical impairments, motor access to the system is a central issue. The choice of an AAC system is strongly dependent on the physical abilities of the client to manipulate the input to the system. DeCoste's (1997) assessments will all provide important input into making the choice of the AAC system. This process is best conducted in collaboration with other professionals, such as occupational and physical therapists who can assist with the motoric evaluation, as well as with teachers and family members who need to facilitate the client's use of the system in everyday settings. The SLP should not try to make this decision in isolation.

The choice of a symbol system for the communication aid must be considered carefully, too. Even pictorial systems have varying degrees of transparency (how close the icon is to the thing it represents) and complexity (how many aspects of the symbol need to be processed and decoded), as we discussed in Chapter 3. Bridges et al. (1999) and Millikin (1997) addressed this issue in detail. Moreover, Preissler (2003) found that children with severe disabilities often fail to understand that pictures represent objects, and simply make associations between pictures and objects without knowledge of their referential function. This means that if we use a picture system, such as the Picture Exchange Communication System (PECS; Bondy, Tincani, & Frost, 2004), we need to make sure that children develop the understanding that a picture stands for a class of objects.

As a general guideline, we will want to provide more iconic systems (such as pictures or drawings) for children with developmental levels less than 18 months, although a small set of more symbolic items can be learned even at low developmental levels (Ronski & Sevcik, 1996). More symbolic representations, such as Sign or Blissymbols, are appropriate for children with developmental levels greater than 18 months. In general, written systems are used with clients whose developmental levels are at least school age, although pre-literacy experiences and instruction in alphabet letters should be provided at much earlier points in development for all clients.

Systems that include a speech generating device have been shown to encourage not only increases in communicative expression but in vocalization as well (Mirenda, 2003; Paul, 1998; Ronski & Sevcik, 1996; Sigafoos, Didden, & O'Reilly, 2003). Brady (2000) showed that using Voice-Onset Communication Aids (VOCAs) in joint attention routines also increased children's understanding of the words being introduced. Whenever possible, clients who need AAC—even those with low cognitive levels—should be provided with electronic VOCAs. And this advice becomes easier to implement as technology advances. For example, voice output systems such as Proloquo2go have been developed for iPhone and iPad platforms that allow children to select symbols to be spoken aloud by the program (Sennott & Bowker, 2009). These platforms provide enhanced opportunities for children who use AAC to interact with peers in ways that are more appealing and less stigmatizing than traditional communication books and boards.

In choosing lexical items to include in AAC systems for older clients, we will want to include words (or signs, Blissymbols, or

other symbols) for the functions that are typically expressed in early speech, but we also want to consider words for other functions that are more appropriate for the daily living situations in which the client operates. These might include symbols for the objects the client uses in vocational activities, for chores that are part of the daily living curriculum, or for recreational activities that are part of the leisure-time program. Crestani, Clendon, and Hemsley (2010) and Fried-Oken and More (1992) discussed in detail some issues surrounding selecting a lexicon for AAC users. Beukelman and Tice (1990) developed a software program (the Vocabulary Tool Box) that allows for the development of a customized lexicon to be used in conjunction with a computer-assisted AAC system. Fallon, Light, and Paige (2001) developed a questionnaire method that enlists parents' help in selecting the most appropriate first vocabulary for children beginning an AAC system that clinicians may wish to use in the endeavor.

For children with severe hearing impairment (HI) who are at the emerging-language stage, use of a total communication (TC) system is especially appropriate. Although TC is not, as we discussed earlier, appropriate for teaching grammatical aspects of language because of the mismatch between the syntactic rules of English and American Sign Language (ASL), it is ideal for demonstrating the early symbolic aspects of language, using single words and two-word combinations. TC can be used to introduce symbolic communication to children with severe HI and to get them to express early semantic relations with single signs and two-sign combinations. When language level moves beyond the two-word stage, the clinician will be in a good position to observe the aspect of the TC signal, auditory or visual, for which the client shows a preference. This information is very helpful in deciding, in conjunction with other information about the client and family, whether to concentrate further instruction in the oral modality or whether ASL will be a more accessible system for this client. When older clients with emerging language produce close to 50 different lexical items, using whatever communication system was developed for them, we should begin to encourage them to combine symbols to express the semantic relations typical of this period. Vertical structuring and milieu teaching, using both the mand-model and incidental teaching approaches we discussed in Chapter 3, can be adapted to clients who use AAC systems. Many of the other programs listed in Appendices 6-7 and 7-3 also can be useful for helping parents encourage clients to make the transition to multisymbol productions. Again, in working with older clients with emerging language we want to use age-appropriate materials, topics, and scripts to encourage this transition. Instead of using dolls and toys to do vertical structuring activities, for example, we can use daily living or recreational contexts. If a client is learning to shelve groceries as a vocational activity, we might do some vertical structuring of object-location relations in this context. As the client works, we might say, "You put soap there. You put the soap on the shelf. Tell me your job." If the client says "soap," we can reply, "Where are you putting it?" If the client says "shelf," we can respond, "Yes, you put the soap on the shelf." We can then wait for a response from the client. If it contains the target two-word phrase ("soap shelf"), we can praise lavishly. If not, we can model the two-word utterance again and go on to another vertically structured model. Binger, Maguire-Marshall, and Kent-Walsh (2011); Fey (2008); and Sutton, Soto, and Blockberger (2002) discuss additional approaches aimed at

moving children who use of AAC from one-word to grammatical productions.

As we saw when talking about providing clients with AAC in Chapter 6, teaching the client to use the system is only half the battle. The other half is getting communication partners to interact with the client around the AAC. Johnston, Reichle, and Evans (2004) described the barriers communication partners face in interacting with AAC users. The important point to remember, however, is that, in developing an effective AAC system, we will need to go beyond teaching it to the client; we will also need to work directly with parents, teachers, and peers to encourage and support them in making the system work for the client. Using more normative platforms, such as smart phones and notepad computers, can help in this endeavor. In addition, *aided language stimulation*, the use of the AAC device on the part of adults for language input as well as for the client to use in production, has been shown to be effective in AAC users' learning of new words (Dada & Alant, 2009).

Emergent Literacy

Normally developing toddlers engage in a variety of pre-literacy activities around book reading and storytelling during the emerging language period (Snow, Burns, & Griffin, 1998). Children with disabilities who function in this stage need similar opportunities to develop basic pre-literacy skills. If even minimal reading and writing skills can be developed, they greatly enhance a client's opportunities for communication and independent living. We talked about some techniques for doing so in Chapter 4. In working with clients who are functioning in the emerging language stage, we want to emphasize to parents the importance of book reading and storytelling and remind them that their child can benefit from such opportunities. Books chosen for these clients should contain simple pictures that can be labeled or described with a few words. Real stories with plots and multiple characters will probably be too advanced for children at this stage to comprehend. Showing children simple, attractive pictures in books and labeling them with one- and two-word descriptions will be appropriate for now. Parents can be encouraged to do this kind of simple book "reading" whenever they have time on their hands with their child, such as when they are waiting for transportation or for a professional visit. Even if only a magazine is available in the waiting room, rather than a real children's book, parents can be advised to find attractive pictures in it (such as pictures of babies or animals in ads) and to provide simple labels as they show the pictures to the child. Pictures on smart phones and notepad computers can be used in a similar way. In this way the time the parent spends with the child can be used productively, and other times during the family's busy day will not have to be set aside.

Other literacy-related activities also can be suggested for both home and school. Parents can be encouraged to talk about writing and its functions by showing the shopping list when they go to the store, leaving written messages for family members on the refrigerator, and reading aloud the signs they encounter on the street or at the doctor's office. Parents also can invite clients to "write" letters and thank-you notes to friends and family, even if they begin by only drawing or scribbling. Teachers can be urged to display print—in the form of alphabet posters, signs displaying classroom rules and routines, labels for objects, and so on—around the classroom at the client's eye level (not the

teacher's!). We also can advise that teachers give clients access to "literacy artifacts," such as letters for felt boards and magnetic boards; paper stapled into books for drawing, writing, and pasting labeled pictures; and ample materials for writing and drawing that are adapted to the clients' physical limitations. These simple opportunities can provide an easily taken path toward the development of reading and writing skills. These skills, in turn, can make a great deal of difference in the communicative ability and potential for independence in clients with severe disabilities. Peibly and Koppenhaver (2001), Sturm and Clendon (2004), and Wood and Hood (2004) discuss ways to include book sharing and literacy activities in intervention programs for children who use AAC. Some of these recommendations are outlined in [Box 7-10](#).

For children such as these who come from culturally different backgrounds, we want to encourage the development of emergent literacy skills, but we'll need to be sensitive to the different ways in which parents from these cultures traditionally interact with their children. Many will be more comfortable telling stories orally than reading to their child from a book. When this is the case, we should encourage parents to tell their children as many stories as they can and to tell the same stories again and again. We can help parents find library books that contain pictures of culturally relevant items and events that they can label and discuss with their child. As described in Chapter 5 we'll want to encourage parents to read to their children in the language in which the parents are most comfortable, even if that is not English. If reading is not an activity in which parents want to engage, we can urge them to provide some of the other kinds of early literacy experiences we talked about instead. The point is to find the kind of activity the parent likes and feels good doing with the child, even if it is not the one we would prefer. By collaborating with the parents to develop an emergent literacy program that works for their family, rather than telling them what they "should" do to develop pre-literacy skills,

we have a better chance of ensuring cooperation and success. This issue actually pertains to the whole enterprise of supplying an AAC system (Parette, Huer, & Wyatt, 2002). We need to work with families to find a way to make the AAC system a viable means of communication for the client within the context of their values and preferences.

CONCLUSIONS

Assessment and intervention for the child functioning at the 18- to 36-month level will always be family-centered, since the family is the social system that has the greatest impact on the life of a developmentally young child. Being family-centered, as we have seen, means being responsive to the interests and concerns of the family; being sure that they are involved in all the decisions made about assessment and intervention for the child; and respecting their culture, traditions, and personal style. When assessing communication in a child at the level of emerging language, we need to make use of a variety of informal procedures that allow us to look at how the child uses and understands communication in natural settings. The goal of the assessment of communication is to learn not only what clients can say in terms of sounds, words, and sentences, but also what they understand, what nonverbal means of communication are available to them, and what play and gestural abilities are present. Integrating information from the assessment of all these areas allows us to develop an intervention program that makes the best use of the skills the child has to build more mature communication. Parents may participate as agents of this intervention but do not have to be the only agents. As always, we want to provide an appropriate mix of services that best meets the needs of the particular child and family.

Let's see how this approach might work for the little boy we met at the beginning of the chapter, Joey.

BOX 7-10 Emergent Literacy Intervention Strategies for Children with Emerging Language who use AAC

Model literacy activities: encourage parents and teachers to demonstrate their use of books to get information and entertainment, writing lists, labeling objects in the environment with signs, and so on.

Make literacy artifacts attractive and accessible: print menus for school lunches and song sheets for favorite songs, label photos of favorite people and activities, make sure children have opportunities to write and draw with interesting materials, such as MagnaDoodle, EtchASketch, alphabet letters made from felt, plastic, etc.

Provide opportunities to request specific books and reading activities: include pictures of favorite books and several reading related options ("pick a book," "read to me," "read it again," "turn the page") on communication boards.

Provide adapted writing opportunities: for example, put a marker through a hole cut in a tennis ball or a pencil on a headstick.

Use multimedia: Interactive storybooks on CD-ROM or downloadable "apps" can be used to increase interactions with texts.

Increase story participation: Put a series of pictures copied from a favorite book on a communication board overlay and have the client "retell" the story by pointing to the pictures, or program a VOCA to emit story elements so the student can "retell" it.

Build from these routine productions to develop concepts (if an overlay for "Over the River and Through the Woods" has been made, use the "over" symbol in other contexts, such as Simon Says, in which the client instructs peers to go *over*, *under* and *through*) and multiword expressions (encourage client to pair "over" symbol with another to describe events, such as *over the river*, *over the bridge*, *over the barn*).

Encourage the development of phonological awareness: pair known pictures on the communication board with their written form in which first or last letters are underlined. Make a page of all /b/ words and talk with child about how all the words on the page start with the same sound; encourage the child to point to other objects in the environment that begin with the same sound; provide a "sounds like" symbol on the communication board, and help children identify words that "sound like" boat (e.g., coat, float, goat) using pictures or yes/no responses.

When Joey went to the doctor for his next checkup and was still talking very little, the pediatrician recommended a speech and language evaluation.

Ms. Bauer, after reviewing his medical records and audiological report, interviewed the parents about Joey's feeding, babbling, and social skills. Joey's parents told Ms. Bauer that Joey did not have any trouble with feeding, but he had been a somewhat "unhappy" baby, crying more and babbling less than they remembered his brother doing. They reported that he made some sounds now, but most sounded like "aa-aa" instead of like the /bababa/ they heard from most babies. He seemed so uninterested in people and didn't babble back and forth the way his brother had.

Ms. Bauer talked with them about what they thought Joey understood, asked the parents to describe how Joey did get his messages across, and how the parents felt about his communication. She then explained that she wanted to observe how Joey played and how he communicated with familiar people and that she also would like them to make an audio recording at home so she could hear the kinds of sounds Joey made. She suggested that a comprehensive developmental assessment might be helpful and that they consider starting this process by taking Joey to a psychologist who could do a cognitive evaluation before she did the communication evaluation.

Ms. Bauer also talked with the parents about their concerns for Joey's ability to take part in a preschool program and about their worries for his success in school when the time came. Joey's parents told her that they had a lot of concerns about his ability to get along in preschool, especially since his mother was planning on going back to college in the fall and needed to have him in day care several days a week. His father especially worried that Joey would not be able to make it in school and might be put in a special class. They were very eager for Ms. Bauer to assess speech and language, but they did not want Joey to have an IQ test. They thought he was too young and didn't want him labeled "retarded." They would be happy to make a recording at home, though.

Ms. Bauer told them that she appreciated their willingness to make an audio recording and respected their desire not to have him labeled too early. She talked with them about what they wanted most for him to get out of any intervention program she developed. She explained that many children with slow speech development do "grow out of" their slow start, but she agreed with the parents that it was wise not to take chances with such an important part of development. She stated again her concern that Joey might need a more comprehensive assessment, but agreed to do a preliminary evaluation. She said she would also like to do an informal assessment of cognitive skills that was not an IQ test. Joey's parents agreed to this approach. Ms. Bauer devised an assessment plan for Joey (Table 7-13).

After gathering the assessment data, Ms. Bauer concluded that Joey's play skills were restricted to non-appropriate uses of objects with little evidence of symbolic play, even in response to a model. He showed a restricted range and limited frequency

of communicative intents and showed poor comprehension and response to his name, and a lack of comprehension strategy use. He had a phonetic inventory of only six consonants. He rarely put more than one consonant in an utterance, had an expressive vocabulary of 16 words, and almost never combined words spontaneously into sentences, although he did produce some longer utterances that appeared to be frozen chunks he'd heard, usually from TV commercials. The communicative intent of these utterances was often difficult to interpret. Ms. Bauer explained these results to the parents. She let them know that she thought Joey's problems might extend beyond language to a more pervasive disorder. She reiterated her preference for a multidisciplinary evaluation to explore his problems more fully.

Joey's parents were not ready for this step. They wanted Ms. Bauer to "teach him to talk." They felt if he would just begin talking normally, his other problems would go away. They begged Ms. Bauer to work with him. Ms. Bauer explained that she didn't believe she could teach Joey to talk normally, at least not in a short period of time, and she felt strongly that he had other needs. She offered a compromise. She would agree to see Joey for 3 months and would attempt to teach him, not to talk per se, but to increase his communication. At the end of the 3 months, if she still felt his needs were more pervasive, the parents would be asked to have a full evaluation done. If the full evaluation indicated the need, continued intervention would use a more integrated approach, incorporating findings from the entire team.

Ms. Bauer's interim intervention plan focused on using communication temptations to increase the range of communication. She planned to use a milieu teaching approach to increase use of consonants in communication and eventually to add expressive vocabulary items to his repertoire. Ms. Bauer also wanted to work on developing conventional and symbolic play skills. She used part of each session to model this behavior with toys Joey was most interested in and asked the parents to carry over these modeling activities at home. She encouraged the parents to continue to model a wide range of words to Joey as he played. The parents and Ms. Bauer worked together to figure out what intents Joey was conveying by his use of frozen phrases from TV. When they discovered his intentions, they provided a simple one- or two-word conventional utterance to use to express the same idea.

Joey continued to use some of his inappropriate language and still was content to play alone with his rubber bands a lot of the time. He still showed limited pretend play, although he could imitate more appropriate use of toys in structured play sessions. At the end of the 3-month trial period, Ms. Bauer discussed progress with Joey's parents, and they agreed to the multidisciplinary assessment they had discussed earlier. They were glad to see the growth Joey had shown. They saw more clearly now, from the observations Ms. Bauer discussed with them and from their understanding of Ms. Bauer's work with Joey, what he could do, as well as the areas in which he remained different from other children.

TABLE 7-13 Assessment Plan for Joey

Area to be Assessed	Assessment Tool
Nonverbal cognitive skill	Dunst procedures for assessing sensorimotor development
Symbolic play activity	Nicolich play assessment from observation of a structured parent-child play session
Vocal skills	Vocal assessment from audiotape made during home play session
Nonverbal communication	Communication Intention Worksheet assessment from observation of an unstructured parent-child play session
Receptive language	Informal comprehension procedures
Phonological skills	Phonetic inventory and SSL derived from audiotape made during home play session
Productive lexicon	<i>Language Development Survey</i> filled out by parents
Productive semantics and syntax	Speech-sample analysis of audiotape made during home play session if LDS vocabulary is larger than 50 words

STUDY GUIDE

- I. Early Assessment and Intervention
 - A. Discuss the pros and cons of early intervention for delayed language development in toddlers.
 - B. What is meant by “children with emerging language” in this chapter?
 - C. What is involved in “family-centered” intervention for toddlers? Why is it important?
 - D. Describe the communication skills seen in normally developing 18-month-olds in terms of comprehension, vocabulary size, sentence structure, and phonology. Do the same with 24-month-olds and 30-month-olds. How does this information affect practice in early assessment and intervention?
 - E. What is the purpose of a symbolic play assessment? Describe levels of play and gesture and how they can be used to conduct a play assessment.
 - F. What are the components of a communication assessment for children with emerging language?
 - G. What formal tools are available for assessing the 18- to 36-month age range?
 - H. What is the rationale for using informal assessment procedures for children with emerging language?
 - I. How can nonverbal communication be assessed? What are the three dimensions of the assessment?
 - J. Discuss the role of cultural differences in assessing parent-child communication.
 - K. Describe formal and informal methods available for assessing comprehension in children with emerging language. Why is it important to look not only at what the child understands but at what comprehension strategies he or she uses?
 - L. How can speech-motor development be assessed in children with emerging language?
 - M. Give three methods of collecting a speech sample from children with emerging language. What are the pros and cons of using speech samples to assess vocabulary size in children with emerging language? Of using parent report?
 - N. Describe two methods of assessing phonological skill in children with emerging language. Why are independent phonological assessments more appropriate than relational methods for children with emerging language?
 - O. Describe the methods you would use to assess semantic-syntactic development in children with emerging language.
 - P. Describe the decision process for determining whether and in what areas children with emerging language can benefit from communication intervention.
 - Q. How does family-centered practice affect decisions about intervention for toddlers? What are its implications for who will deliver the intervention?
 - R. Under what circumstances would you attempt to develop symbolic play skills in a child with emerging language? How would you do it?
 - S. What methods would you use to increase nonverbal communication skills in a child with emerging language?
 - T. How can maladaptive forms of communication be handled?
 - U. Under what conditions would you include work on receptive language in the communication program for a child with emerging language? What methods would you use?
 - V. Would you work on diminishing phonological process use by a child with emerging language? Why or why not? If not, what phonological skills would you target?
 - W. What considerations go into choosing a first lexicon?
 - X. What methods would you use to increase the vocabulary size of a child with emerging language?
 - Y. Describe one CD, one hybrid, and one CC approach to developing two-word combinations in the speech of a child with emerging language.
 - Z. Do you think adult speech to children with emerging language should be telegraphic? Why or why not?
- II. Considerations for Toddlers with ASD
 - A. What instruments have been developed specifically for diagnosing ASD?
 - B. What are the areas of communication you would expect to be delayed in toddlers with ASD?
 - C. What are the primary areas of intervention that should be addressed in toddlers with ASD?
- III. Considerations for Older Clients with Emerging Language
 - A. Discuss adaptation of assessment methods that can be used to evaluate communication skills in older clients at the emerging language stage.
 - B. What aspects of intervention are unique to older, severely impaired clients with emerging language?
 - C. Describe the role of emerging literacy skills in older clients with emerging language. What functions can emergent literacy serve for these clients?
 - D. Define Functional Communication Training and its role in AAC provision for children with severe disorders.
 - E. Talk about considerations in developing emergent literacy for children from culturally different backgrounds.

General Communication Assessments for Children Younger than 3 Years of Age

Instrument	Comment
<i>Assessing Prelinguistic and Early Linguistic Behaviors in Developmentally Young Children</i> (Olswang, Stoel-Gammon, Coggins, & Carpenter, 1987)	Provides assessments of phonology, expressive language, preverbal communication, play, and cognitive antecedents to word meaning; norm-referenced data from relatively small sample.
<i>Birth to Three Assessment and Intervention System—Second Edition</i> (Ammer & Bangs, 2000)	Provides examiners with an integrated, three-component system for screening, assessing, and intervening with children ages birth to 3 years; the three component parts are the Screening Test of Developmental Abilities, Comprehensive Test of Developmental Abilities, and the Manual for Teaching Developmental Abilities.
<i>Carolina Curriculum for Infants and Toddlers—Third Edition</i> (Johnson-Martin, Attermeier, & Hacker, 2004)	Provides an in-depth whole child assessment and intervention covering 26 domains of development for children ages birth to 24 months; looks at areas of cognition, communication, social skills, fine and gross motor skills; excellent sections on preverbal and verbal communication.
<i>The Capute Scales: Cognitive Adaptive Test and Clinical Linguistic and Auditory Milestone Scale</i> (CAT/CLAMS; Accardo & Capute, 2005)	Norm-referenced 100-item screening and assessment instrument; surveys broad range of communicative behaviors and visual-motor functioning; designed for use by pediatricians with infants 1–36 months.
<i>Communication and Symbolic Behavior Scales—Developmental Profile</i> (CSBS DP; Wetherby & Prizant, 1993)	Norm-referenced screening tool for identifying infants at risk for developmental delay or disability. Includes assessment of symbolic play, nonverbal communication, and expressive and receptive language. Contains a checklist, caregiver questionnaire, and behavior sample.
<i>Early Language Milestones Scale—Second Edition</i> (ELM-2; Coplan, 1993)	Designed for pediatric screening; pass/fail criterion only; evaluates expressive, receptive, and visual skills; best for identifying severe delays.
<i>Early Learning Accomplishment Profile</i> (E-LAP; Glover, Preminger, & Sanford, 1995)	Developed to assess gross and fine motor skills and social, cognitive, and language areas; designed to identify the developmental level of functioning.
<i>Early Screening Profile</i> (Harrison et al., 1990)	Screens development in cognitive language, motor, self-help/social, articulation, health, development, and home environments. Helps identify children at risk for learning problems.
<i>Environmental Prelanguage Battery</i> (MacDonald & Carroll, 1992)	Assesses early prelinguistic communication skills such as play, gestures, imitation, and following directions.
<i>Expressive One-Word Picture Vocabulary Test—2000 Edition</i> (EOWPVT [2000]; Brownell, 2000)	Offers an in-depth assessment of a child's speaking vocabulary by asking the child to make word-picture associations; comprehensive manual provides standard scores, scales scores, stanines, percentiles, and age equivalents.
<i>Interaction Checklist for Augmentative Communication—Revised</i> (Bolton & Dashiell, 1991)	Developed for clients with physical barriers to speech, but provides assessment of interactive behaviors useful with developmentally young clients.
<i>Language Development Survey</i> (LDS; Rescorla, 1989)	Screening tool for evaluating expressive language; parent-report instrument; good validity on identifying language delay in toddlers.
<i>MacArthur-Bates Communicative Development Inventories—Second Edition</i> (Fenson et al., 2007)	Parent-report instrument with scales for assessing expressive and receptive vocabulary sizes and early grammatical production; reports good validity when compared with direct observation measures.
<i>Preschool Language Scale—Fifth Edition</i> (PLS-5; Zimmerman, Steiner, & Pond, 2011)	Measures a broad range of receptive and expressive language skills; provides standard scores and percentile ranks in addition to age equivalents for auditory comprehension, expressive communication, and total language; PLS tasks are ordered to reflect acquisition of sequential developmental milestones in language.

Instrument	Comment
<i>Receptive One Word Picture Vocabulary Test—2000 Edition</i> (ROWPVT [2000]; Brownell, 2000) <i>Receptive-Expressive Emergent Language Scale—Third Edition</i> (REEL -3; Bzoch, League, & Brown 2003)	Provides an assessment of receptive vocabulary; child indicates (from four possible alternatives) the picture that represents a word spoken by the examiner; test is individually administered and can be administered and scored in 20 min. Parent-interview instrument; tends to overestimate comprehension level.
<i>Reynell Developmental Language Scales III</i> (Edwards et. al., 1999)	Designed to measure language skills in young or developmentally delayed children; the verbal comprehension scale measures receptive language skills (both verbal and nonverbal), and the expressive language scale assesses expressive language skills using three sets of items (structure, vocabulary, and content).
<i>Rossetti Infant and Toddler Language Scale</i> (Rossetti, 1990)	Used to assess preverbal and verbal communication skills and interaction in children from birth–3 yr; criterion-referenced measure looks at language comprehension, language expression, interaction, attachment, gestures, pragmatics, and play.
<i>Sequenced Inventory of Communication Development—Revised</i> (SICD-R; Hedrick, Prather, & Tobin, 1984)	Diagnostic test that evaluates the communication abilities of children with and without intellectual disability who are functioning between 4 mo and 4 yr of age.
<i>Symbolic Play Test—Second Edition</i> (Lowe & Costello, 1988)	Assessment provides an objective indication of child's early concept formation and symbolization; includes a format for informal data collection of play features.
<i>Test of Early Language Development—Third Edition</i> (TELD-3; Hresko, Reid, & Hammill, 1999)	Yields an overall spoken language score and includes scores for subtests of receptive and expressive language; psychometric qualities include demographics, reliability, validity, and limited bias.
<i>Test of Pretend Play</i> (ToPP; Lewis & Boucher, 1999)	ToPP is designed to assess the three different types of symbolic play: substituting one object for another object or person; attributing an imagined property to an object or person; or making a reference to an absent object, person, or substance; ToPP also is designed to assess whether the child can incorporate several symbolic actions into a meaningful sequence, and a child's level of conceptual development.
<i>The Nonspeech Test</i> (AAC) (Huer, 1988)	Standardized on preschoolers and children with multiple disabilities in schools and institutions; this test of receptive and expressive language is popular for children who are nonspeaking; test yields an age equivalency score in monthly increments from 0 to 48 mo.
<i>Transdisciplinary Play-Based Assessment: A Functional Approach to Working with Young Children—Revised</i> (Linder, 1993)	A dynamic comprehensive instrument that provides information to conduct play sessions that combine insights of parents with the expertise of a transdisciplinary team; uses specific observation guidelines to assess a child's cognitive, social, emotional, communication, and language development during play time.

Training Resources for Parents of Toddlers

Resource	Source	Comments
"Learning Through (and from) Mothers" (Levenstein, 1971)	P. Levenstein; in <i>Childhood Education</i> , 48 (December), 130-134, 1971	"Toy Demonstrators" use verbal interaction techniques with mothers and their 2-yr-old children.
"Pre-Computer Skills for Young Children" (Symington, 1990)	L. Symington; in <i>Exceptional Parent</i> , 20, 36-38, 1990	Suggests activities to train young disabled children skills for using the computer.
"Taking Turns" (MacDonald & Gillette, 1985)	J. MacDonald & Y. Gillette; in <i>Exceptional Parent</i> , 15 (September), 49-52, 1985	Focuses on turn-taking as a primary approach to language learning.
<i>Adaptive Play for Special-Needs Children: Strategies to Enhance Communication and Learning</i> (Musselwhite, 1986)	C.R. Musselwhite; San Diego, CA: College-Hill Press, 1986	Intended for professionals, paraprofessionals, and parents; has information on early communication through speech: parent-child dialogues, puppetry; early augmentative communication; annotated bibliography on adaptive play.
<i>Beautiful Beginnings: A Developmental Curriculum for Infants and Toddlers</i> (Raikes & McCall-Whitmer, 2006)	H. Raikes & J. McCall-Whitmer; Baltimore, MD: Brookes Publishing	Activity-based approach to enhancing infant and toddler development in communication, gross motor, fine motor, intellectual, discovery, social, self-help, and pretend.
<i>Beyond Baby Talk</i> (Apel & Masterson, 2001)	K. Apel & J. Masterson; New York: Prima Publishing	A book for parents that answers questions about their baby's speech and language development.
<i>Developmental Therapy for Young Children with Autistic Characteristics</i> (Bachrach, Mosley, Swindle, & Wood, 1978)	A.W. Bachrach, A.R. Mosley, F.L. Swindle, & M.M. Wood; Baltimore, MD: University Park Press, 1978	Samples of techniques and materials, routines and environments, activity periods, learning experiences, and home programs designed for 0-3 yr; for teachers and parents; organized from "stage one" through normal developmental sequences.
<i>Early Childhood STEP</i> (Dinkmeyer et al., 1989)	D. Dinkmeyer, et al; Circle Pines, MN: American Guidance Service	Kit including parent guide, videos, posters; Spanish version available.
<i>Early Communication Games: Routine Based Play for the First Two Years</i> (Casey-Harvey, 1995)	A. Casey-Harvey; Austin, TX: Pro-Ed	Examines and provides examples of play for children birth-24 mo, developing initial communication skills.
<i>Ecological Communication System</i> (MacDonald & Gillette, 1986)	J.D. MacDonald & Y. Gillette; Columbus, OH: The Ohio State University, 1986	Two treatment modules available: (1) turn-taking with actions—functional interactive play and (2) turn-taking with communications (initial conversation).
<i>Everybody's Different: Understanding and Changing Our Reactions to Disabilities</i> (Miller & Sammons, 1999)	N. Miller & C. Sammons; Baltimore, MD: Brookes Publishing Co., 1999	Discusses ways in which personal thoughts, feelings, and questions about disabilities can obstruct effective communication between people; offers strategies, activities, and exercises that enhance development and social relationships.
<i>Every Day Matters: Activities for You and Your Child</i> (Washburn Child Guidance Center, 1997)	Washburn Child Guidance Center; Circle Pines, MN: American Guidance Service, 1997	Simple, easy-to-use suggestions for parent-child learning experiences; covers five developmental areas: discipline, self-esteem, infant care, language, and coordination.
<i>Games to Play with Toddlers—Revised Edition</i> (Silberg, 2002)	J. Silberg; Beltsville, MD: Gryphon House, 2002	Games that develop areas important for the growth of a 12- to 24-mo-old: language, creativity, coordination, confidence, problem-solving, and gross motor skills.

Continued

Resource	Source	Comments
<i>Games to Play With Two Year Olds—Revised Edition</i> (Silberg, 2002)	J. Silberg; Beltsville, MD: Gryphon House, 2002	Games that develop areas important for the growth of a 2-yr-old: language, coordination, social interactions, and problem-solving skills.
<i>Helping Babies Learn: Developmental Profiles and Activities for Infants and Toddlers</i> (Furuno, Reilly, Hosaka, Inatsuka, & Fabey, 1998)	S. Furuno, K. O'Reilly, C. Hosaka, T. Inatsuka, & B. Falbey; San Antonio, TX: Communication Skill Builders, 1998	Shows parents how to help children ages birth–3 yr realize their fullest potential; emphasizes parent-child partnerships by focusing on developmental activities occurring in daily life; provides parents with reproducible activities to integrate all aspects of development.
<i>It Takes Two to Talk: A Practical Guide for Parents of Children with Language Delays</i> (Hanen Centre, 2004)	J. Pepper & E. Weitzman; Toronto, Ontario, Canada: The Hanen Centre, 2004	Parent handbook focuses on the child's attempts to communicate; guides parents to respond in ways that facilitate interaction; "You Initiate Opportunities for Language Learning" (the second part of the guide) suggests ways to increase opportunities for communication.
<i>Learning Through Play: A Resource Manual for Teachers and Parents</i> (Fewell & Vadasy, 1983)	R. R. Fewell & P.F. Vadasy; Hingham, MA: Teaching Resources Corp., 1983	Contains activities to stimulate learning targeted at birth–3 mo, 4–6 mo, 7–9 mo, 10–12 mo, 13–18 mo, 19–24 mo, 25–30 mo, and 31–36 mo, specific sections on language.
<i>Learning to Talk Is Child's Play</i> (Ausberger, Martin, & Creighton, 1982)	C. Ausberger, M. Martin, & J. Creighton; Tucson, AZ: Communication Skill Builders, 1982	For parents, preschool teachers; stresses use of responsive language teaching through adult-child dialogues.
<i>Parent Articles for Early Intervention</i> (Dunn-Klein, 1977)	M. Dunn-Klein; Austin, TX: Pro-Ed, 1977	Compilation of articles for parents of children, ages birth–3 yr, who have communication and physical disorders; articles are grouped by 12 major topics, including communication, cognitive development and play, family support, and personal care; each article answers commonly asked questions, includes detailed instructions and additional resources for further reading, and suggests related activities and materials.
<i>Parent-Child Habilitation</i> (IHRP, 1987)	Infant Hearing Resource Publications; Portland, OR: IHRP, 1987	Uses play as teaching milieu, gives techniques for teaching speech and language to hearing-impaired toddlers.
<i>Preparing Children to Learn: Parent Letters</i> (McNay, Kottwitz, Simmons, McLean, 1996)	V. McNay, E. Kottwitz, S. Simmons, & M. McLean; San Antonio, TX: Communication Skill Builders, 1996	Covers assessment, planning, and implementation for children ages 1 mo–5 yr, addressing the full span of developmental objectives in interpersonal interactions and communication, cognition, receptive language, expressive language, and movement.
<i>Puppetry, Language, and the Special Child: Discovering Alternative Languages</i> (Renfro, 1984)	N. Renfro; Austin, TX: Nancy Renfro Studios, 1984	Describes activities to integrate visual and verbal aspects of puppetry to enhance language and communication.
<i>Read, Play, and Learn</i> (Linder, 2004)	T. Linder; Baltimore, MD: Paul H. Brookes, 2008.	Uses popular children's books to promote early learning.
<i>Systematic Training for Effective Parenting</i> (Dinkmeyer, McKay, Dinkmeyer, 1997)	D. Dinkmeyer, L. McKay, & S. Dinkmeyer; Windsor, Berkshire, SL4 1DF, UK: NFER-Nelson Darville House, 1997	Available in book and video form.
<i>Talking with Your Baby</i> (Honig, 1996)	A.S. Honig; Syracuse University Press, 1996	How to help low-literacy parents, and parents for whom English is a second language, enhance the literacy and cognitive development of their children in the home environment through daily activities.
<i>Teach Me Language</i> (Freeman & Dake, 1998)	S. Freeman & L. Dake; New York: SKF Books, Inc., 1998	Program designed for teaching parents with a step-by-step manual of instructions, explanations, examples, games, and cards to attack language weaknesses common to children with PDD and other disabilities.
<i>The Home Stretch</i> (Cansler, 1982)	D. Cansler; Winston-Salem, NC: Kaplan Early Learning Company, 1982	Encourages parents to use unit topics at home (e.g., body parts, people, family, clothing).
<i>Children with Disabilities</i> (Batshaw, 2007)	M. Batshaw, L. Pellegrino, N. Roizen; Baltimore, MD: Brookes Publishing Co., 2007	Comprehensive volume offers advice on a wide range of issues, such as finding the right physician, learning important care techniques, and fulfilling educational requirements. Detailed chapters explore behavior management, treatment, nutrition, therapy services, and medicines.

Resource	Source	Comments
<i>You and Your Small Wonder: Parent Books of Learning Activities for Infants and Toddlers</i> (Karnes, 1997)	M. Karnes; Circle Pines, MN: American Guidance, 1997	Includes two books full of playlike learning activities, building skills in natural ways; clear instructions and photos for demonstration; includes mealtime, changing, bath time, and indoor/outdoor activities.
<i>Ready for Preschool</i> (Hertzog, 2008)	N. Hertzog; Waco, TX: Prufrock Press, 2008	Provides detailed guidance to parents on how to foster development of skills to be successful in preschool in their children; how to use every-day experiences to teach these skills.
<i>Parent Articles 2: More Articles Enhance Parent Involvement</i> (DeFeo, n.d.)	A. DeFeo, San Antonio, TX: Pearson, n.d.	Information covering a variety of topics, from explanations of specific disorders to the emotional challenges of having a child with special needs; several articles written by parents.
<i>Special Children, Challenged Parents: The Struggles and Rewards of Raising a Child with a Disability, Revised Edition</i> (Naseef, 2001)	R. Naseef, Baltimore, MD: Brookes Publishing, Co.	Provides information regarding resources, such as support groups and communicating with professionals, for parents of children with disabilities; written by a clinical psychologist who is a parent of a child with autism.
<i>Talk to Me, Baby! How You Can Support Young Children's Language Development</i> (Bardige, 2009)	B. Bardige; Baltimore, MD: Brookes Publishing Co.	Guidebook for parents and professionals on how to interact with young children to support emergent language; suggestions for activities and ways to utilize every-day interaction.
<i>Handprints: Home Programs for Hand Skills</i> (Piaraccini & Vance, 2001)	V. Pieraccini & D. Vance; Arizona: Imaginart	Articles for parents and easy-to-do home activities to improve development of hand skills.
<i>Lip Prints: Home Program for Oral-Motor Skills</i> (Hanson, 2004)	J. Hanson	Utilizes child-based play and play-based therapy to treat and prevent oral motor, feeding, swallowing, and/or articulation problems; articles cover range of topics such as neonatal intensive care unit and transitioning to food and utensils.

<i>Activity-Based Intervention</i> (Bricker & Pretti-Frontczak, 2004)	Executive Producer: D. Bricker Co-Directors: P. Veltman and A. Munkres Brookes Publishing Co. PO Box 10624 Baltimore, MD 21285	Intervention techniques provide daily routines and activities to foster skill development in children with special needs. 14 min.
<i>Beginning Language Connections</i> (Educational Productions, 1995)	Educational Productions 7412 SW Beaverton-Hillsdale Highway, Suite 210 Portland, OR 97225	The first in a 4-video series called <i>First Steps</i> . 30-min video, practice exercises, trainers manual, overheads, handouts, and activities. Shows how adults' interactions with infants and toddlers are key to their language learning. Available in Spanish.
<i>Building Conversations</i> (Educational Productions, 1995)	Educational Productions 7412 SW Beaverton-Hillsdale Highway, Suite 210 Portland, OR 97225	The fourth in a 4-video series called <i>First Steps</i> . 30-min video, practice exercises, trainers manual, overheads, handouts, and activities. Shows how animated exchanges with verbal and nonverbal children continually enhance their emerging communication and social skills. Available in Spanish.
<i>Learning Language and Loving It, Teaching Tape</i> (Hanen Centre, 1993)	The Hanen Centre 1075 Bay St., Suite 515 Toronto, ON M5S 2B1	Provides an overview of typical development from birth–3 yr; designed to accompany Hanen Early Language Parent Program.
<i>Let's Talk</i> (Educational Productions, 1988)	Educational Productions 7412 SW Beaverton-Hillsdale Highway, Suite 210 Portland, OR 97225	33-min video, Facilitator's Guide. Describes communication skills that invite children and encourage talking, how to avoid asking questions that stop conversations, and how to correct a child's speech/language errors in a positive way.
<i>Now You're Talking</i> (Educational Productions, 1988)	Educational Productions 7412 SW Beaverton-Hillsdale Highway, Suite 210 Portland, OR 97225	30-min video, Facilitator's Guide. Describes how to add to the child's topic and extend conversation, how to ask questions that stimulate thinking and problem solving, how to support all of a child's efforts to communicate.
<i>Oh Say What They See</i> (Educational Productions, 1985)	Educational Productions 7412 SW Beaverton-Hillsdale Highway, Suite 210 Portland, OR 97225	Methods used in indirect language stimulation: self-talk, parallel talk, reinforcement, and expansion methods.
<i>Reading the Child's Message</i> (Educational Productions, 1995)	Educational Productions 7412 SW Beaverton-Hillsdale Highway, Suite 210 Portland, OR 97225	The second in a 4-video series called <i>First Steps</i> . 30-min video, practice exercises, trainers manual, overheads, handouts, and activities. Takes a close look at messages babies and toddlers are sending from birth. Available in Spanish.
<i>Successfully Educating Preschoolers with Special Needs: Ages 2 ½ to 5, A Guide for Parents, A Tool for Educators</i> (Thal et al., 2002)	G.M. Hanlon; Baltimore, MD: Brookes Publishing	30-min video, offers practical information about preschool education and special education services for children ages 2 ½ to 5.
<i>Successfully Educating Preschoolers with Special Needs: Early Intervention for Ages Birth to Three</i> (Hanlon, 1999)	G.M. Hanlon; Baltimore, MD: Brookes Publishing	60-min video; gives parents an introduction to the early intervention process.

Resource	Source	Comments
<i>Talking with Young Children</i> (Educational Productions, 1995)	Educational Productions 7412 SW Beaverton-Hillsdale Highway, Suite 210 Portland, OR 97225	Part of a 4-video series called <i>First Steps</i> . 30-min video, practice exercises, trainers manual, overheads, hand-outs, and activities. Demonstrates how children must understand what words and concepts mean before they can begin to use words or signs to communicate. Available in Spanish.
<i>The Handicapped Child: Infancy Through Preschool; Program 5—Cognitive/Language Development</i> (Concept Media, 1978)	Concept Media PO Box 19542 Irvine, CA 92714	Elements for fostering language development are discussed; sequence of language development briefly described.
<i>First Steps: Supporting Language Development with Infants, Toddlers, and Twos</i> (Teaching Strategies, Inc., n.d.)	Teaching Strategies, Inc.; Washington, DC:	Teaches techniques to support language development and encourage facilitative parenting practices.
<i>Helping Your Child Learn</i> (South Dakota Deafblind Project, 1992)	South Dakota Deafblind Project; South Dakota Department of Education	This three-video series advises parents in when, where, what, and how to teach their child with special needs to communicate, interact socially, and participate in activities of daily living.

Assessment of Developing Language

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Describe family-centered assessment procedures appropriate for preschool clients.
2. List areas outside of communication abilities that are necessary to assess in young children.
3. Discuss issues and methods for screening for communication disorders in preschool children.
4. Discuss the uses and abuses of standardized tests for communication assessment during the preschool period.
5. Describe a range of criterion-referenced and observational methods for assessing speech and language development.
6. Analyze samples of communication including conversation and narration.
7. Discuss the application of assessment methods for children at early stages of language development to older students with severe communication disorders.

Jerry was the third child in the family, so when he was a little slower than his sisters to get started talking, no one thought much about it. But when he entered preschool at age 4, his teacher, Mrs. Hamilton, noticed that his speech seemed immature. He made mistakes that other 4-year-olds in the class didn't make, such as leaving out the little words and endings in sentences. He'd say, "Me a big boy," and "I want two cracker." He seemed not to know the words for many things other children could name, and he often used vague or idiosyncratic labels to refer to common objects. He called a pineapple a "spiky," for example. Some of his words were hard to understand, too. He made some errors, such as saying /fAm/ for thumb, that were like those made by lots of 4-year-olds, but he also left out sounds and parts of words in ways that weren't typical of children his age. He said "mato" for tomato and /bA/ for bug. All these errors combined made his speech difficult to understand at times. Mrs. Hamilton noticed that when Jerry had trouble making himself understood, he often became angry, sometimes hitting or pushing the child who did not get his message.

At the parent conference that fall, Mrs. Hamilton told Jerry's parents that she felt Jerry was a bright child but that he was having some trouble with his communication skills. She explained that these problems might go away by themselves in time, but at present they were causing Jerry some frustration and interfering with his ability to get along with other children and succeed in the classroom. She recommended that Jerry's parents consider having a speech-language pathologist (SLP) evaluate Jerry's language skills and determine whether some intervention would help him navigate this period of his development.

Jerry is a preschool child with a specific disorder of language learning. Like many such children, his problem includes several aspects of language development; these problems often affect his ability to get along in the social situations he encounters when he ventures outside the family circle. Jerry exemplifies just one of the many kinds of preschool children a practicing SLP encounters. Other such children have hearing losses. Some may be developmentally delayed or have autistic behaviors. Others have accompanying emotional disturbances or a history of experiential problems, such as parental substance abuse. Still others may have suffered acquired neurological damage. Some, of course, are older than the typical preschool-age range. Whatever other conditions surround the language disorder, though, the children we will consider in this and the next chapter share certain language characteristics:

- They have expressive vocabularies larger than 50 words.
- They have begun combining words into sentences.
- They have not yet acquired all the basic sentence structures of the language.

For children who are of preschool age but have expressive vocabularies smaller than 50 words or are not yet combining words, more appropriate assessment and remedial strategies can be found in Chapter 7, which deals with the emerging language period when first words are beginning to appear and a few two-word combinations may be used. Children who are functioning at the emerging-language level, even if they are of preschool age or older, benefit most from procedures aimed at this early phase of language development.

The period we'll call the "developing language" stage is the one that occurs when normally speaking children are between 2 or 3 and 5 years of age. Another way to describe this period is to say that it refers to language levels in Brown's stages II through V. That is, children with developing language have mean lengths of utterance (MLU) of more than two but generally not much more than five morphemes. These children are in the most explosive stage of language development, the period in which they move from telegraphic utterances to the mastery of basic sentence structures. For children with typical development, this process begins around 2 years of age and proceeds rapidly during the preschool period. For children with disorders of language learning, though, the process is more protracted. They may be a good deal older than 2 when they start it, and they may be well into school age before they complete it. When we discuss language assessment and intervention at the developing language level here and in Chapter 9, we are referring to those children whose *language* functions in the period between Brown's stages II and V. The children themselves, though, may be chronologically older than preschool age. The principles of this and the following chapter can be applied to children of any age who have started combining words but have yet to develop the full set of forms for expressing their intentions.

FAMILY-CENTERED ASSESSMENT

The first thing we need to know when we begin an assessment is that the Individuals with Disabilities Education Act (IDEA) makes specific requirements for the inclusion of the family in the evaluation and intervention processes. IDEA reminds us that we need to enlist parents as partners in the assessment process from the very beginning for any child with a disability. Recent IDEA regulations stipulate that parents must be specifically included as members of the Individual Educational Planning (IEP) team. They require that parents' concerns be considered during the evaluation process and that all evaluations be disclosed to families at least 5 school days before any hearing process takes place. The regulations state further that the parents must be notified about any services delivered to the child and given progress reports at least as often as parents of typical children are. They must be told of their right to see any records or reports about their child and of their right to seek an evaluation outside the local educational agency, if they choose. A preassessment conference is often very useful to allow parents to meet members of the assessment team, to explain families' legal rights to them, and to give parents enough information and answer their questions so that they can give informed consent to the assessment procedures.

Family-centered practice means more than merely complying with these legal requirements, though. In addition, it means that we rely on parents as an important source of information about the child. We discussed interviewing parents on developmental and history information in Chapter 2. Standardized interview formats, such as the *Vineland Adaptive Behavior Scales II* (Sparrow, Cicchetti, & Balla, 2005), can be used to help establish general developmental level. Questionnaires about general and medical history can be used to gather information from parents as well. But family-centered practice also means that, from the first encounter with the family, we convey to them a sense of "being in this together," a desire and intention to address the family's concerns about the child and to respect the family's point of view.

As discussed in Chapters 6 and 7, family involvement does not necessarily mean that the family must be evaluated along with the child. This is often both off-putting and threatening to families. It does mean that we need to seek the family's perspective on the child's strengths and weaknesses, identify the family's concerns for the child, and find out what priorities the family has for the skills the child needs to learn to function most effectively. Let's take Jerry as an example. Suppose the family takes Jerry to the preschool assessment center of the local educational agency. The parents talk with the assessment team leader and the SLP there about Mrs. Hamilton's recommendation. They express some dismay that Jerry seems to be having so much trouble, since they haven't experienced difficulties with him at home. They say Mrs. Hamilton thinks he is bright, but now they wonder whether he might be retarded. Their main concern is helping Jerry get along better in school and avoid any problems when he reaches kindergarten. They don't want him labeled a "troublemaker."

How would we use a family-centered approach to assessment to deal with these concerns and use them to structure the assessment plan? First, we should try to assure parents that our evaluation reflects the "real" child. Assessment should be completed over a period of time in a variety of contexts, using naturalistic activities (Rini & Hindenlang, 2007). We want to ensure that the family is confident the team truly has a sense of who their child is. Second,

we want to gather extensive information about the child from family members, so that they are assured that their perspective on the child is being included in the appraisal. Whether we used structured measures, like the *Vineland* or more informal interviews, we want to acknowledge that parents have the broadest and deepest knowledge about their child, and that we hope to draw on that knowledge as we conduct the evaluation. Third, all of the parents' anxieties should be addressed. If the parents are worried that Jerry might have intellectual disability (ID), even if the assessment team does not believe this is very likely, his cognitive and adaptive skills ought to be assessed. Referral can be made for a psychological evaluation to assess cognitive level. Alternatively, the speech-language clinician might ask the family whether they would be comfortable with her doing an informal cognitive assessment based on play behavior. She might assure the parents that if the child performs within the normal range on this measure, further assessment might not be necessary, but if she has any concerns at all about cognitive functioning, a referral for testing in greater depth can be made. The speech-language clinician also can offer to use the *Vineland Adaptive Behavior Scales II* (Sparrow, Cicchetti, & Balla, 2005) to assess adaptive behavior, since a child must function below the normal range in *both* cognitive and adaptive areas to qualify for a diagnosis of ID. In any case, a family-centered approach requires that we take the parents' concerns seriously and incorporate them into the assessment plan.

Next, the clinician would need to address the discrepancy between the parents' perceptions and those of Mrs. Hamilton. The assessment team might ask the parents to talk about how they see Jerry in relation to the family, how he gets along with his sisters, and whether and how he plays with children in the neighborhood. They might then ask the parents to review some of Mrs. Hamilton's concerns, to have them check their thoughts about Jerry's social skills with what the teacher told them to see whether the two seem to be in line in any areas. We want to give the parents the impression that we trust their viewpoint and at the same time help them to see that everyone—including children—acts differently in different situations. A clinician might explain that seeing Jerry interact with several different people through the course of the evaluation helps both the parents and the assessment team to get a fuller picture of Jerry's language and social skills. The team might request permission to observe Jerry playing with his mother or sister, either in their home or at the center, and also to go to Jerry's preschool and do an observation there.

The team also would want to work with the parents to plan the evaluation to include not only areas in which problems are currently obvious, such as his immature speech and language skills, but also areas about which parents have other concerns. Jerry's parents expressed doubts about his ability to succeed in kindergarten. In this case, the team might suggest including a special education evaluation in the assessment. This would give the team a chance to look at his readiness skills and give the parents more information about the skills Jerry has that will equip him for kindergarten, what skills he is lacking, and what skills they might be able to help him acquire. The team also can assure the parents that the recommendations that come out of the assessment will not only address basic oral language but also will provide information about ways the parents can help get Jerry ready for school. The team could then check with the parents to be sure (1) that what they have heard makes sense to them, (2) that it addresses the concerns they have about Jerry, and (3) that any other questions they forgot to ask or that came to mind during the discussion are addressed and considered in the evaluation plan.

What if, after the assessment takes place, conflicts arise between the family and the clinician or team about the recommendations based on the assessment? Suppose, for example, that the team evaluating Jerry believes that he needs a special preschool program that would overlap with the hours of his neighborhood preschool program, so that he was unable to attend both. Suppose further that the parents feel very strongly that they want him in the neighborhood program. How would a family-centered approach address such a problem? Again, the key is an attitude of respect and accommodation for the family on the part of the assessment team. Can a compromise solution be reached that would meet both the team's need to feel Jerry was receiving adequate services and his parents' need to see him in a "normal" preschool setting? Can a discussion with the parents allow both parties to express their concerns in a context of mutual respect so that either the parents or the assessment team might modify their views about what is best for Jerry? If no mutually acceptable solution can be reached, can the team defer to the parents' decision and cordially invite them to bring Jerry back at a later time so that everyone can reconsider his situation? These tactics would convey to the family that the team understands that the parents have Jerry's best interests at heart and that they are doing the best they can to provide for his needs as they perceive them. Such an attitude allows disagreements to take place without alienating the families of the children we hope to be able to serve. There may be rare cases in which we suspect serious abuse or neglect, which might make us less comfortable with deferring to parental decisions. Even in these situations, though, we want to be able to maintain a relationship with the family. This is the only way we will be able to serve the child. In such cases, it is incumbent upon us to make referrals to the appropriate social service agencies that can address the caretaking problem. However, we would still want to take a family-centered stance in trying to set up services to meet the needs of the child.

Family-centered assessment, then, does not mean assessing families, trying to identify their weaknesses. Instead it means including families in the process of deciding why, what, and how to assess each child. Moreover, it means taking the family's concerns seriously and treating parents as a valid and reliable source of information about the child. It also means respecting the parents' decisions about their child, even when we disagree with them. While it is always appropriate to try to resolve disagreements through compromise and courteous persuasion, we will not always succeed. When we do not, family-centered clinicians defer to the family's judgment and try to maintain a relationship with the family that will make them feel welcome to come back another time, when the child's problems, or their feelings about them, change. Bruce, DiVenere, and Bergeron (1998); Dunst, Trivette, and Deal (1988); and Rini and Hindenlang (2007) provided additional discussion on family-centered practice.

ASSESSING COLLATERAL AREAS

When we talked about assessment in Chapter 2, we discussed the importance of assessing every client referred for a speech or language disorder in the areas of hearing and speech-motor ability. This principle, of course, holds true for the child with developing language. Audiometric screening and, if necessary, full evaluation should be conducted, even if hearing problems have never been mentioned in the child's medical history. Similarly, any child in the developing language phase who has difficulty talking should

receive a thorough speech-motor assessment, following the guidelines given in Chapter 2.

Some language clinicians, particularly those in private practice settings, function independently in their assessment activities, making referrals to other professionals for information on collateral areas outside their own field of expertise. The majority of clinicians who do assessment in school, hospital, or nonprofit agency settings, though, usually conduct their assessments as part of a multidisciplinary or transdisciplinary team, as we discussed in Chapter 2. It could be, though, that information on collateral areas of particular interest will not be within the expertise of anyone else on the team. When this is the case, a referral to an outside agency may be necessary. Alternatively, the clinician might decide to do some informal evaluation in these areas to get a sense of how they relate to the child's language functioning.

We've talked before about the dangers of requiring that certain cognitive skills be present before language skills are taught. If we see a child of preschool age who is unable to accomplish any object permanence tasks, for example, we do not want to conclude that the child cannot learn language. We know such simple prerequisite relationships do not capture the complexity of the interactions of cognitive and linguistic development (Johnston, 1994; Mainela-Arnold, Evans, & Alibali, 2006; Nelson, 2000; Whitmire, 2000a). Still, we do need to know something about the child's general level of development, to help both in planning appropriate contexts and materials for intervention and in deciding on appropriate language goals. If, for example, a 7-year-old with a developmental delay is found to have a general developmental level of 15 to 18 months, we would want to focus on acquisition of single symbols, and stimulating language growth, using the goals and approaches advocated for children with emerging language (see Chapter 7) for some time. If, on the other hand, another developmentally delayed 7-year-old had a general developmental level of 30 to 36 months, we would focus more on approaches appropriate for children with developing language (that is, we would move more quickly from single words to two-word combinations and on to three- and four-word sentences and might consider more focused, clinician-delivered intervention). The point is that knowing something about general developmental level does not necessarily dictate what language skills are targeted, but it may influence the context, pace, and intensity of the intervention.

SCREENING FOR LANGUAGE DISORDERS IN THE PERIOD OF DEVELOPING LANGUAGE

Remember that *screening* is deciding whether a child is significantly different from other children in terms of language skills. To make this decision, we want a procedure that is relatively quick yet psychometrically sound, so that it is a fair measure of whether the child performs within the normal range. The point of screening is not to assess all areas of language but to get an idea about the child's general level of functioning in both of the major modalities: comprehension and production. Screening measures should always be standardized instruments; deciding whether a child is significantly different from other children is exactly what standardized tests do best.

Many standardized instruments are commercially available for screening purposes with preschool populations. A sampling of these is presented in [Appendices 8-1](#) and [8-2](#). One example is the

General Language Screen (Stott, Merricks, Bolton, & Goodyer, 2002), a parent-report screening measure for 3-year-olds that appears in Figure 8-1. Luinge, Post, Wit, and Goorhuis-Brouwer (2006) provide another example of a screening instrument designed to identify language delays in children 12 to 72 months old. Chiat and Roy (2007) suggest using a modified word repetition test, similar to but simpler than the non-word repetition measures used with school-aged children, to identify risk for language impairment in preschoolers.

Choosing which instrument to use should not be based on random factors, such as what happens to be on the shelf or what was advertised in a recent catalog. As clinicians, we have a responsibility to review all testing instruments and to choose those that are

the most efficient and fair. For screening, that means that we want a test that is short and psychometrically sound. Reasonable levels of sensitivity and specificity have been reported for some preschool language screeners, including the *Early Language Milestone Scale—2* (Coplan, 1993), the *Language Development Survey* (Klee, Pearce, & Carson, 2000; Rescorla, 1989), the *Clinical Linguistic and Auditory Milestone Scale* (Clark, Jorgensen, & Blondeau, 1995), the *Levett-Muir Language Screening Test* (Levett & Muir, 1983), the *Screening Kit of Language Development* (Bliss & Allen, 1984), the *Fluharty Preschool Speech and Language Screening Test* (Allen & Bliss, 1987), the *Language Use Inventory* (O'Neill, 2007), the *Sentence Repetition Screening Test* (Sturner, Funk, & Green, 1996), and the *Structured Photographic Expressive*

Child's Name _____ Parents' Name _____	
DOB _____ Age _____ Phone# _____	
Please circle the answer below that best describes your child's use and understanding of language at the present time.	
1. When your child speaks can he or she be understood by you?	YES NO
2. When your child speaks can he or she be understood by other members of your family?	YES NO
3. When your child speaks can he or she be understood by other strangers?	YES NO
4. Can your child string three or more words together in a meaningful way?	YES NO
5. Can your child follow two-step instructions; e.g., "Pick up the block and put it on the table?"	YES NO
6. Can your child answer "where" questions; e.g., "Where is your teddy?"	YES NO
7. Can your child make a choice when asked; e.g., "Would you like milk or orange juice to drink?"	YES NO
8. Can your child place objects in, under or on when asked; e.g., "Put the toys in the box." "Put the cup on the table." "Put the shoes under the chair."	YES NO
9. Does your child enjoy listening to simple stories?	YES NO
10. Is what your child says usually meaningful and relevant to the ongoing conversation or situation?	YES NO
11. Can your child say more than fifty words?	YES NO
12. Are you confident that your child has never had a hearing loss, including one that came and went over a period of weeks or months?	YES NO
If the answer to one or more of the above questions is NO, in your view is there any obvious, known reason why this should be so? _____ _____	

FIGURE 8-1 *General Language Screen* for 3-year-olds. A NO response on any item is a trigger for further evaluation. (Reprinted with permission from Stott, D., Merricks, M., Bolton, P., & Goodyer, I. [2002]. Screening for speech and language disorders: The reliability, validity and accuracy of the General Language Screen. *International Journal of Language and Communication Disorders*, 37, 133-150.)

Language Test—Preschool: Second Edition (Dawson et al., 2004; Greenslade, Plante, & Vance, 2009). When we look for a screening measure, we should examine test manuals for information on sensitivity and specificity, as well as other psychometric properties (see Chapter 2). It is important to know the properties of the tests we use and to choose tests with properties that are the best match for the assessment question that we are trying to answer. In practice, this means we have an obligation to read the statistical sections of the manuals of all the tests we use and to base decisions about their use not only on their efficiency and attractiveness, but also on how well their measurement properties stack up. There ARE such things as bad tests: tests that are poorly constructed and do not give enough psychometric information for us to decide whether they test fairly and accurately. But there are very few tests that are so good that they are right for every situation. Clinicians need to match tests to their needs on the basis, at least to some extent, of the tests' statistical properties.

There's one other consideration when doing screening: a child's level of risk. When deciding whether to provide a more extensive evaluation, it is wise to factor risk into the decision. Harrison and McLeod (2010), after reviewing the literature on risk and studying a nationally representative sample of 4- to 5-year-old children, reported that boys were at greater risk for language impairment than girls, as were children with hearing impairments, and those with difficult temperaments. Family history of speech, language, reading, or learning problems also increased risk (Barry, Yasin, & Bishop, 2007). Knowing these risk factors can help to determine which children who may not fail screening, but simply score toward the low end, could benefit from additional evaluation in universal screening situations, or which children should get high priority for screening in others.

In addition to the risk factors for language delay identified by Barry et al. (2007) and Harrison and McLeod (2010), we also need to think about risk for reading problems in preschoolers with oral language delays. Serry, Rose, and Liamputtong (2008) discuss the role the SLP can play in identifying preschoolers at risk for reading failure on the basis of their oral language difficulties. Both Flax et al. (2009) and Serry et al. (2008) suggest that, in addition to phonological processing delays, receptive language disabilities are key risk factors for the emergence of reading problems in preschoolers. These findings suggest that preschool children for whom teachers report delays in phonological awareness skills (such as identifying words that start/end with the same sound or rhymes) or in general comprehension are good candidates for screening and perhaps more in-depth assessment to reduce the risk of reading failure by shoring up weak phonological and language skills during the preschool years.

USING STANDARDIZED TESTS IN ASSESSING DEVELOPING LANGUAGE

Everything we just discussed about choosing screening instruments for children with developing language applies to choosing more in-depth standardized tests as well. Remember that the thing standardized tests do best is to show whether a child is significantly different from children in their norming samples, so every standardized test we use has a screening component. That means that when we choose a standardized instrument, we need to be sure that it provides us with some more information than we got from the initial screening test. If the standardized test only tells us again that

the child is different from other children in general language skills, we have wasted our time and the child's in giving it. Let's look at what information is provided by standardized tests available for assessment of this stage of language development and see how they might enhance our evaluation of the client with developing language. A sample of standardized tests designed for use with children in the developing language phase is given in [Appendices 8-3 and 8-4](#).

Let's take Jerry as our example again. Suppose Jerry, after failing a screening measure given by the SLP, is given the *Test of Language Development—4 Primary* (TOLD-4:P; Newcomer & Hammill, 2008) to explore his profile of language skills across a range of components of language. This test provides a standardized measure of several areas of expressive and receptive language and allows us to construct a profile such as the one in [Figure 8-2](#), which displays Jerry's scores on the TOLD-P:4. The profile tells us that Jerry is performing adequately in several areas of receptive language, but that his expressive skills, and particularly his articulation, are low for his age. This profile suggests that we need to focus on expressive areas of language development, including the area of phonology.

Another strategy for obtaining similar information would be to choose several tests, each of which focuses on one area. For example, we might select the *Test of Auditory Comprehension of Language—3* (Carrow-Woolfolk, 1999a) to look at receptive vocabulary and syntax, the *Goldman-Fristoe Test of Articulation—Second Edition* (GFTA-2; Goldman & Fristoe, 2000) to examine single-word pronunciation, the *Expressive Vocabulary Test—2* (Williams, 2007) to investigate productive semantics, and the *Structured Photographic Expressive Language Test—Third Edition* (Dawson, Stout, & Eyer, 2003; Perona, Plant, & Vance, 2005) to explore expressive sentence structures. We could use the results from this test battery, too, to construct a profile that outlines strengths and weaknesses in language skills.

Now let's be clear about what tests such as these would tell us. Like the screening measures, standardized tests tell us whether a child is different from other children. A battery similar to the ones we've outlined here would tell us in what aspects of language a child performs significantly below his or her peers. This information, in turn, would alert us to the areas we would need to address in a remedial program. However, the results of the standardized tests would *not* necessarily tell us what specific forms, functions, and structures to target. They identify areas in which the child is deficient, but they don't pinpoint the specific deficiencies. Why not?

For one thing, they are designed to sample a variety of behaviors within a domain so that they can get a valid comparison across children. That means there won't be many examples of any particular structure. The *Test of Auditory Comprehension of Language—3* (Carrow-Woolfolk, 1999a), for example, has only one item that tests comprehension of plural forms. If Jerry fails that item, would you target plural forms as part of your remedial program? It's hard to say. It's possible that he really doesn't understand the meaning of the plural marker, but there might be other reasons why a child might fail that item. Maybe he wasn't paying very close attention at that moment. Maybe he didn't know the words in the sentence. Before deciding to target plurals, we would want to see more of a *pattern* of performance. A standardized test is not designed to provide that kind of information.

Here's another reason that standardized tests don't give us all the information we need for remedial planning. Take the

Goldman-Fristoe Test of Articulation—Second Edition (Goldman & Fristoe, 2000) or the *Patterned Elicitation of Syntax Test* (Young & Perachio, 1993). These measures will be very effective for showing us whether Jerry is different from other children in articulating single words and imitating grammatical sentences, respectively. However, research shows that although children's scores on standardized and naturalistic language procedures are related, children do not make the same errors on both types of assessment, so we cannot identify forms for remediation from the standard test items (Morrison & Shriberg, 1992; Prutting, Gallagher, & Mulac, 1975; Shriberg & Kwiatkowski, 1980). Moreover some children do better on tests than on naturalistic measures (Condouris, Mayer, & Tager-Flusberg, 2003), suggesting that the tests may not be fully tapping their difficulties in real life communication. Standardized tests, particularly those designed to measure expressive skills, tend to use elicited production formats. Standardized tests of expressive syntax usually require children to imitate sentences spoken by the examiner. Standardized tests of articulation require children to produce single words in response to pictures. Both these formats tend to elicit performance that is substantially different from the performance of the same children in spontaneous speech. Not only do children produce different frequencies of errors in these imitation and citation formats, they make different kinds of errors, too. So knowing the errors Jerry makes on one of these measures doesn't tell us what errors he will make when he actually tries to talk to someone. It's the errors that children make when they actually talk that we need to address in intervention, so we need to know what those are. Standardized tests do not necessarily give us this information. Criterion-referenced measures, such as language sampling, are much more valid and effective for gathering information on the errors children make in real communicative situations.

Does this mean that we should not use standardized tests in assessment? Should we go directly from screening to criterion-referenced measures and language sampling? My opinion is that we should not. Standardized testing is valuable for doing exactly what it was designed to do: pointing out the areas in which the child is performing significantly more poorly than peers. Using standardized tests to identify general areas of deficit is more efficient than doing in-depth criterion-referenced probing in every area. Standardized tests can narrow down the range of areas we need to evaluate with criterion-referenced procedures.

Let's take Jerry as our example again. Standardized testing told us that Jerry's receptive skills are within normal limits. This suggests that we do not need to do any further assessment in these areas. His expressive syntax did exhibit mild deficits, though. Now we need to know specifically and in detail what his expressive errors are like when he tries to communicate in real interactions. That's where criterion-referenced procedures and language sampling come in. But remember: standardized testing was very efficient both in documenting broad areas of deficit and in narrowing the focus of our criterion-referenced evaluation. Using standardized testing in this way to sharpen the focus of the criterion-referenced assessment saves a good deal of time. It also provides the norm-referenced documentation required by many educational and service agencies to qualify the client for intervention. Standardized testing, then, is one aspect of an assessment plan. Used wisely and appropriately, with an understanding of its functions and limitations, it makes the assessment process efficient and economical.

CRITERION-REFERENCED ASSESSMENT AND BEHAVIORAL OBSERVATION FOR CHILDREN WITH DEVELOPING LANGUAGE

Standardized testing is not enough, though. As we have seen, standardized tests don't tell us what mistakes the client makes in real conversation, and these are the mistakes we need to address in intervention. Nonstandardized assessments are needed to complete the picture. Nonstandardized or informal evaluation does not mean the assessment is spontaneous or unplanned. On the contrary, nonstandardized assessment requires *more* planning than use of standardized tests, since the clinician must decide on the linguistic stimuli, specify a developmentally appropriate response, and choose materials and contexts for gathering the data, all without instruction from a standardized procedure. An effective approach to nonstandardized assessment is to compile all the information from the standardized portion, evaluate it, decide what informal assessments are needed, plan them, and collect the data in a subsequent session with the client. This suggests that nonstandardized assessment may not always take place during the formal "evaluation" session with the client, but may happen in the early part of the intervention phase. In other words, assessment may not be complete when the one or two sessions we label as "assessment" are over.

For clinicians working in diagnostic settings, where assessment and making recommendations for intervention are their only tasks, this means that one assessment session is not usually enough. We should plan to see each client at least twice, once for formal assessment and once to do some nonstandardized evaluations that are indicated by the results of the formal procedures. For clinicians who do both assessment and intervention as part of their jobs, this means we should not feel constrained to get all the assessment data during the first evaluation session. Assessment can continue into the intervention period, as it is an ongoing part of the intervention.

Assessing Speech Sound Production

A clinically useful approach to analysis of a child's speech production is to start out just talking with the child for 5 to 10 minutes to get a sense of general intelligibility. Gordon-Brannan (1994) and Morris, Wilcox, and Schooling (1995) discussed issues in assessing intelligibility. Morris et al. advocate using the *Preschool Speech Intelligibility Measure* (PSIM), which consists of having children repeat a list of words. The child's productions are recorded and listeners are asked to judge which word a child says on each trial from a group of similar sounding words (e.g., *warm, store, swarm, for, horn, corn, door, torn, born, floor, storm, and form*). This measure can be very useful for documenting changes in intelligibility over the course of an intervention program. As a more informal measure, it is useful for making an initial determination about whether intelligibility is impaired. The clinician can also rate intelligibility in a short conversation by estimating the proportion of intelligible words. Gordon-Brannan and Weiss (2006) advocate collecting a conversational sample and counting 200 consecutive words within the sample. The clinician then listens to this portion of the sample again, counts the number of unintelligible words, and divides by the number of words in the sample. This figure is then subtracted from 100 to get a percentage of unintelligible words. Beltyukova, Stone, and Ellis (2008) report that this method shows high reliability and discriminatory power. Gordon-Brannan & Weiss (2006) and Coplan and Gleason (1988) provide guidelines for judging when children in

the developing language period show a lower level of intelligibility than would be expected for their age. These are summarized in Table 8-1. *The Children's Speech Intelligibility Measure* (Wilcox & Morris, 1990) is another method available. Coplan and Gleason have shown that children whose intelligibility is below age expectations are at increased risk for the presence of a range of developmental disorders, not just speech delay. In fact, 46% of the children in their study who were identified on the basis of failing an intelligibility screen turned out to have developmental difficulties beyond speech and language, so identifying poor intelligibility in a preschooler should lead to a more intensive assessment of the child's abilities in a range of areas of development.

If the short speech sample indicates that a client is hard to understand, the next step in our clinical procedure would be to do an articulation test. We also might do an articulation test if the child is intelligible but makes more articulation errors than we would expect on the basis of developmental level. Although, as Morrison and Shriberg (1992) showed, articulation tests do not always identify the pronunciation errors children will make in spontaneous conversation, they do reliably show whether a child is significantly different from other children. Articulation tests are relatively quick and easy to administer and score. As such, they are sensible approaches to the problem of deciding whether speech sound production is an area that needs to be addressed in an intervention program. An articulation test can be given to decide whether more information is needed about the child's phonology. If the child scores within the normal range on the articulation test and intelligibility in conversation appears adequate, further assessment of speech sound production is not likely to be necessary.

If a child scores below the normal range on an articulation test or conversational speech is judged hard to understand, we will want to examine the nature of the child's speech sound difficulties. Shriberg (2010) has proposed a classification system for speech sound disorders without known cause in children. For most children in the developing language period, speech delay, which is identified in children 3 to 9 years old who show a pattern of sound deletions and/or substitutions, is the appropriate category label. Although most of these children will eventually develop typical speech, they are at increased risk for literacy delays (Hesketh, 2004; Leita & Fletcher, 2004), as well as social difficulties, like those Jerry's teacher pointed out. For these reasons, intervention is warranted, both to improve speech intelligibility and to help the child develop awareness of sounds so that risk for reading problems is reduced (Gillon, 2005a; Kirk & Gillon, 2007).

Although speech delays are defined by the presence of sound omissions and substitutions, often these errors occur not in isolation, but in patterns. For example, a child may have trouble producing closed consonant-vowel-consonant (CVC) syllables, regardless of the

particular sound that comes at the end of the word. These patterns, which are often referred to as *phonological processes* (Prezas & Hodson, 2010), can sometimes be treated more efficiently than treating each individual sound error separately. For this reason, many clinicians will not only identify the individual omissions and substitutions a child makes, but will look for these kinds of patterns, as well. How would we accomplish this? One way is to look not only at the child's responses to an articulation test, but to examine errors in spontaneous speech, as well. This approach allows us to analyze the child's production at two levels (Williams, 2001): *independent analysis*, which describes what the child produces, regardless of whether it is correct by adult standards, and *relational analysis*, which compares the child's production to adult targets and looks for error patterns. When we assessed speech sound production in the emerging language stage, we used primarily independent analyses. Let's look at examples of the most common approaches to each of these types of analysis for children in the developing language period.

Independent Analysis: Phonetic Inventory

A phonetic inventory tells us what sounds a child says without comparing the child's production with an adult target. To collect a phonetic inventory we simply write down, or check off on a checklist, each consonant a child produces, regardless of whether it is the correct one for that context by adult standards. The articulation test results can be used to collect phonetic inventory information. Each consonant that the client produces in response to the articulation test stimuli, whether correctly or incorrectly used, can be listed. Alternatively, the phonetic inventory can be derived from a sample of conversational speech. All the consonants the client produces can be taken to comprise the phonetic inventory. Each consonant needs to be recorded only once, regardless of how many times it appears. The result is a list of the set of consonants the child produces.

Suppose, for example, that Jerry never produces a /z/ in the appropriate context. We might be tempted to try to teach him "how" to say /z/, perhaps using isolated sound drills and nonsense words. But suppose further that we find /z/ does appear in his phonetic inventory. Perhaps he uses it in one or two words where /d/ is required. Clearly, then, he knows "how" to say /z/. What we need to teach him is not *how* to say it but, as Shriberg (1987) has argued, *when* to say it. In this case, an approach to intervention focusing on whole words and meaningful contrasts, is appropriate. If /z/ never appeared at all in the phonetic inventory, then Jerry really does need to learn "how" to say the /z/ sound and an approach that focuses on motor production may be more appropriate.

Shriberg (1993) has grouped consonants by their normal order of acquisition. He divided the 24 consonant phonemes of English into three groups: the early eight (those that are used first in development), the middle eight (the group that appears next), and the late eight (the group that appears latest in normal acquisition). Shriberg's assignment of consonants to these groups is given in Box 8-1. This scheme can be useful in deciding where in the process of acquiring sounds a client is, based on the phonetic inventory. If the inventory contains only sounds from the earliest group, some articulatory and motor training work may be necessary to elicit later-developing sounds. If the inventory contains sounds from both the early and middle groups, more emphasis might be placed on getting the client to produce these sounds in their correct contexts. If sounds from all three groups are present but speech still contains many errors, then, we would want to concentrate on getting the child to use the sounds he or she already has in appropriate

TABLE 8-1 Expected Relations between Age and Intelligibility in Typically Speaking Children

Age (MO)	Percent Intelligible Words
24	50
36	80
48	100

BOX 8-1 Groups of Sounds Ordered Developmentally

Early 8: /m/ /b/ /j/ /n/ /w/ /d/ /p/ /h/

Middle 8: /t/ /ŋ/ /k/ /g/ /f/ /v/ /tʃ/ /dʒ/

Late 8: /ʃ/ /θ/ /s/ /z/ /ð/ /l/ /ʒ/

Adapted from Shriberg, L. (1993). Four new speech and prosody-voice measures for genetics research and other studies in developmental phonological disorders. *Journal of Speech and Hearing Research*, 36, 105-140.

contexts. If middle and later sounds are present, but many early sounds are missing, we might conclude that this child is showing atypical speech sound development and might look for speech-motor or other organic bases of the disorder.

Phonetic inventories are easy to collect from continuous speech samples, by simply listening to a recording of the sample and writing down or checking off the first appearance of each consonant the client uses. They can be very helpful in deciding which sounds are in the inventory and need not be approached with motor training or articulatory procedures. They also can help identify sounds that are truly absent, suggesting that the child needs to learn “how” to say them. Looking at the distribution of sounds and comparing them with Shriberg’s (1993) scheme also can be helpful in deciding whether speech sound acquisition is delayed or proceeding along a deviant course. Williams (2001) also suggested conducting a distributional analysis of the phonetic inventory to determine in what word positions (initial, medial, final) the child’s sounds appear.

Relational Analysis: Errors and Error Patterns

The relational analysis is used to determine not what sounds the child can say, but what differences exist between the child’s production and adult target forms. Articulation tests give us this information about individual sounds in individual words. But since the 1970s, speech researchers and clinicians have been interested in describing not just individual errors in child speech, but also the patterns or rules that govern these errors. One particular approach to analysis of error patterns has been productive in this research: the use of *phonological simplification processes* to describe sound changes. Simplification processes have been described in detail by many authors, including Ball and Kent (1999); Bauman-Waengler (2004); Bernthal and Bankson (2004); Creaghead, Newman, and Secord (1989); Gordon-Brannan and Weiss (2006); Grunwell (1987); Hodson and Paden (1991); Ingram (1976); and Shriberg and Kwiatkowski (1980). Detailed definitions and discussion can be found in these writings. For our purposes, let’s just say that simplification processes are a way of describing sound changes that appear to be rule-governed attempts, which apply across a class of sounds or syllable structures, to make pronunciation easier. One example of a phonological simplification process is *unstressed syllable deletion*. It applies across the class of words containing more than two syllables and results in productions in which the least stressed syllable is dropped (*mato* for *tomato*). *Velar fronting* is another example. It applies across all sounds produced in the velar position (in English /g/, /k/, and /ŋ/) and results in the production of each one as the corresponding sound produced with the same manner, nasality, and voicing in the alveolar position (/d/, /t/, and /n/, respectively).

There are many ways to conduct process analysis. Some methods resemble articulation testing. These elicit single words or single

sentences from children and apply phonological analysis procedures, analyzing errors according to the type of simplification process used. The *Clinical Assessment of Articulation and Phonology* (Secord & Donohue, 2000), the *Bankson-Bernthal Test of Phonology* (Bankson & Bernthal, 1990), the *Computerized Articulation and Phonology Evaluation System* (Masterson & Bernhardt, 2001), and the *Hodson Assessment of Phonological Patterns—Third Edition* (Hodson, 2004) are some examples. Other approaches provide guidelines for reanalyzing data gathered from an articulation test by means of phonological analysis procedures. Khan and Lewis (2002) have developed one such procedure. Masterson, Bernhardt, and Hofheinz, (2005) showed that single word measures such as these provide sufficient and representative information for phonological evaluation.

A brief conversational sample is a useful adjunct to single word testing, as a check on the representativeness of the single-word sample. Several procedures are available in the literature for organizing this analysis. Bauman-Waengler (2004); Grunwell (1987); Ingram (1981); Lund and Duchan (1993); Owens (2004); Shipley and McAfee (2004); Shriberg and Kwiatkowski (1980); and Williams (2001) provided guidelines for approaches to phonological analysis of continuous speech. Andrews and Fey (1986) suggested procedures for applying Hodson’s analysis scheme for single words to spontaneous speech. These samples can be relatively short; Shriberg and Kwiatkowski (1980) suggest 100 different words produced in spontaneous speech is enough. This would generally involve about 10 to 15 minutes of continuous speech on the part of the child. Since many children with phonological disorders are difficult to understand, Shriberg and Kwiatkowski suggested that instead of using an open-ended conversational format for eliciting the speech sample, as we did when we got our initial general measure of intelligibility, we use a more structured task. We can give the child a complex picture with lots of different items in it to describe, such as the pages found in a “big” Richard Scary book. These kinds of stimuli elicit a sample in which the referents are known and the gloss of the child’s speech is much easier to determine. Whether you use a conversational or picture description format to elicit your sample, you can reanalyze the same sample later for syntactic, semantic, pragmatic, and phonological information. So here’s how a clinician might proceed:

1. Give the child a complex picture book, and ask him or her to tell about some of the things in the picture. Or ask the child to engage in conversation around common play materials with the parent.
2. Audio record the sample.
3. While the child is talking, quickly get down the gloss and phonemic transcription of the first 100 different words. (Have a piece of paper already labeled with two columns [gloss, phonemic transcription] and 100 numbered rows, or use the forms provided by Shriberg and Kwiatkowski [1980].)
4. Later, check the recording for any glosses or transcriptions you aren’t sure about. You also can collect your phonetic inventory during the same pass through the recording. Save the recording for later analyses of other language areas.

Using this approach, we would first conduct the independent analysis, listing each consonant the child produced, regardless of whether it is correct. Next we do the relational analysis, analyzing the child’s first 100 words for error patterns. Shriberg and Kwiatkowski provided detailed guidelines and abundant worksheets for performing this analysis. Basically, in doing these analyses we are looking for the appearance of the common patterns, such as:

1. Final consonant deletion (leaving off the last sound in a CVC word, such as saying /da/ for *dog*).

2. Velar fronting (pronouncing /k/, /g/, and /ŋ/ as /t/, /d/, and /n/, respectively, such as saying /tʌb/ for *cub*).
3. Stopping (pronouncing fricatives as the corresponding stops, such as saying /to/ for *sew*).
4. Palatal fronting (producing palatal sounds in the alveolar position, such as saying /su/ for *shoe*).
5. Liquid simplification (substituting another sound for one of the liquids [l/ and /r/], such as saying /wawi pap/ for *lollipop*).
6. Assimilation (making two sounds in a word more alike, such as saying /dadi/ for *doggy*).
7. Cluster reduction (dropping one or more sounds from a cluster or making substitutions within the cluster, such as saying /pe/ for *play*).
8. Unstressed syllable deletion (leaving off the least stressed syllable in a multisyllabic word, such as saying /næ næ / for *banana*).

This analysis can tell us (1) which sounds are subject to simplification in which words; (2) what patterns of errors appear across sounds; (3) whether processes are fading out at the typical time in the typical order (Figure 8-3 provides information on the typical developmental sequence of phonological processes). (4) whether atypical processes appear (that is, whether a large number of errors cannot be assigned to any of the common patterns listed above); and (5) how consistent the use of each process is for each sound; that is, whether the child uses the process in every context or only in some. For example, does the child always substitute stops for fricatives, or only some of the time? With the information provided by this analysis, we can begin to formulate an appropriate intervention program for a child with speech delay. Williams, McLeod, and McCauley (2010) present detailed discussions of the various methods available for remediating speech sound disorders in children.

Shriberg and Austin (1998) reported that 30% to 40% of children with language disorders also have speech problems. Furthermore, 15% to 20% of children with speech delays have concomitant problems in vocabulary, grammar, or both. This suggests that we must be careful not to let the child's unintelligibility blind us to possible language components of the disorder. Every child who

presents with speech sound delay should receive a thorough language assessment, to identify any areas of linguistic disorder that might not be obvious because the child's speech is so hard to understand.

Assessing Phonological Processing: Preventing Reading Failure

The term *phonological processing* refers to a child's ability to perceive, store, retrieve, and manipulate sounds for language (Serry, Rose, & Liamputton, 2009). (It's important to keep this term separate from the term *phonological processes*, which refers to the rule-governed simplifications that are common in young children's speech.) Phonological processing includes phonological awareness (skills such as the ability to detect rhymes, number of syllables, and first/last sounds in words), rapid automatic naming (such as saying the days of the week quickly), and phonological memory (seen in the ability to repeat unfamiliar nonsense words). These phonological processing abilities grow during the preschool period, and are well-known to be related to learning to read and spell (Anthony et al., 2007; Gillon, 2004; Serry et al., 2008). The implication for SLPs is that these abilities are another aspect of phonological development to consider in assessment, so that if we detect weaknesses in these areas, we can build some phonological processing activities into the child's program, as a means of preventing later difficulties in learning to read (Gillon, 2005a). For younger preschoolers, under the age of 4, informal assessment of the ability to recognize and produce rhymes—by asking children to find two pictures out of three whose names rhyme or to complete rhymes such as “You like dogs and he likes ____ (frogs)” —can alert the clinician to deficits in these earliest-emerging phonological processing abilities. For 4- to 5-year-olds, informal assessment of the ability to provide a word with the same first sound as a given word (“Can you think of a word that starts with the same sound as *dog*?”), to count syllables in words (Can you clap for each part in the word *hippopotamus*?) can help determine whether more in-depth assessment of phonological processing is indicated. Schuele, Skibbe, and Rao (2007) provide additional guidance on assessing

FIGURE 8-3 Developmental sequence of phonological processes. (Adapted from Grunwell, P. [1987]. *Clinical Phonology* [2nd ed.], p. 229. Baltimore, MD: Williams & Wilkins.)

Informal assessment of phonological processing can include having children identify rhymes in rhyming picture books.

phonological processing. Appendix 11-3 has more information on standard instruments for phonological process assessment. Finally, Shriberg et al. (2009) have developed a non-word repetition test appropriate for children as young as 3 years that can also be useful in identifying difficulties in phonological processing. Here's the bottom line: children with speech and/or language delays as preschoolers are at risk for reading failure in school, and deficits in phonological processing increase this risk. For this reason, some assessment of phonological processing for preschoolers with speech and/or language delays can identify children at highest risk for difficulty in learning to read and can guide the clinician to include activities to promote phonological processing into the speech/language intervention program. There is some evidence that doing so will help to lessen later reading problems in these children (Gillon, 2005a; Justice, 2006; Skibbe et al., 2008).

Criterion-Referenced Language Assessment

Just as standardized assessments of speech sound production do not always answer all our questions about a child's speech, standardized assessments of language skill, although able to point out general areas of deficit, do not tell us everything we need to know about a client's linguistic functioning. To get a fuller picture, we need to use some nonstandardized measures to tell us what kinds of errors the child makes in more naturalistic contexts. In general, standardized assessments for children with developing language can detect deficits in several broad areas. Depending on the tests used, the following areas can usually be examined:

- Receptive vocabulary (by responding to words by picture pointing)
- Expressive vocabulary (by naming pictures or defining words)
- Receptive syntax and morphology (by pointing to one of several pictures, including contrasting foils that depict a sentence spoken by the examiner [Point to: "The *boys* are here."])
- Expressive syntax and morphology (by imitating sentences or filling in blanks with words containing grammatical morphemes ["I have a dress; you have two . . ."])

Several areas of language function are usually *not* covered by standardized tests. These include pragmatics and semantic areas other than associating words with pictures. A standardized test battery,

then, can usually point out whether a child has deficits in each of the broad areas outlined in the preceding list. Once the areas of deficit have been identified, though, we want to look at each one more closely, using informal assessment procedures to examine specific error types and pinpoint targets for intervention. We also want to look at pragmatic and semantic areas not covered by standardized tests, if history and discussions with the family indicate that the child might be having any trouble in these areas. That's where nonstandardized, criterion-referenced procedures come in.

Vocabulary

Guidelines for Vocabulary Assessment and Intervention

Generally speaking, the size of receptive vocabulary is larger than that of expressive vocabulary in children, and children can commonly recognize a pictured item by name, even though they may not be able to come up with the label for the same item in a confrontation naming task. The conventional wisdom is that if a child can produce a word, he or she must understand what it means. This is not entirely true, though. Research on children's word-learning strategies (Bloom, 2001; Dollaghan, 1985; Rice, Buhr, & Nemeth, 1990) suggests that preschoolers can pick up some notion of a word's meaning from very brief exposure, but that the meaning will be quite limited until the child acquires additional experience with the word. Researchers call this strategy "fast mapping" (Carey, 1978). What it implies for us as clinicians is that children's understanding of word meaning, even when they produce the word themselves, may be more limited than the adult's understanding of the meaning of the same word. The result is that it is difficult, with children in the developing language phase, to make a clear differentiation between the knowledge required to understand a word and the knowledge required to use it. It is not entirely true to say that "comprehension precedes production," because a word may very well be produced even when comprehension of the word is very limited, by adult standards. This implies that clinicians should handle receptive and expressive vocabulary knowledge in an integrated way.

What does this mean in practice? It implies that we should not worry too much about assessing vocabulary separately in each modality and then treating each modality separately. If a child does poorly on a receptive vocabulary test, such as the *Peabody Picture Vocabulary Test IV* (Dunn & Dunn, 2006), the logical next step in assessment is to use criterion-referenced methods to look at what words the child has difficulty understanding. But there would not seem to be a need to teach these words receptively first, before trying to get a child to say them. Since children normally say words with only limited knowledge of their meaning, production can be targeted from the beginning of the intervention program. In short, we would recommend a strategy, following Lahey (1988), of focusing on comprehension during assessment but on production during intervention.

There are two exceptions. First, for children with very limited speech sound production, words should be selected for production that the child can pronounce or at least approximate. Schwartz and Leonard (1982) showed that children in the early stages of speech sound acquisition are selective about words that they try to produce, attempting only those that have at least a beginning sound that is already in their repertoire. For clients who are still in this very early stage of speech development, then, pronounceability should be a consideration in choosing words that we are trying to get the child to say. Intervention for vocabulary might focus on

receptive skills while work is going on to increase the child's speech sound repertoire.

The second exception has to do with word retrieval. It may be that a child has a normal receptive vocabulary size on a standardized test but uses very few words in spontaneous speech or does very poorly on a naming test such as the *Expressive One-Word Picture Vocabulary Test—Revised* (Brownell, 2000). We may suspect that the problem is the inability to recall words when needed for production rather than lack of knowledge of the words. Word-retrieval skills are often assessed in test batteries for learning-disabled children of school age, since word retrieval problems commonly coexist with reading deficits (Brackenbury & Pye, 2005; Wolf, Bally, & Morris, 1986). Retrieval is not typically included in the assessment of the child with developing language. However, if word retrieval appears to be a problem—because of a large decrement on an expressive vocabulary test when compared with the score on a receptive measure, or because the child seems to have trouble recalling words in spontaneous conversation—intervention should focus more sharply on helping the child to recall and produce the words he or she already knows, in addition to increasing vocabulary size.

Let's summarize our suggestions for working with vocabulary at the developing language level. Because of the issue of fast mapping and the complicated relationship between comprehension and production of word meaning in the developing language period, we would advocate the following strategy for handling vocabulary issues:

First, assess receptive vocabulary skills with a standardized instrument.

- If the child scores below the normal range, do criterion-referenced assessment of word classes that are important in the child's communicative environment. Target words identified in this assessment, using both receptive and expressive intervention activities, with the emphasis on production. Control for pronounceability with children in the early stages of speech acquisition.
- If the child scores within the normal range on the receptive vocabulary test, but history or parent or teacher report indicates concern about word use, assess expressive vocabulary with a standardized naming test. Watch for signs of word-finding problems, such as circumlocutions, overly general labels (*thingy*), or inability to name items responded to correctly on the receptive test. If there is evidence of a retrieval problem, focus intervention on practicing the recall and production of already known words, providing strategies such as using phonetic and semantic cues for retrieval (see details in Chapter 12).

Methods of Criterion-Referenced Vocabulary Assessment

Standardized measures of vocabulary typically tell us whether a child's ability to recognize and produce the names of items pictured in the test is similar to that of other children. Sometimes we want to know what a child knows about a particular category of words. We may need this information because this set of words is important for the child's success in preschool. Colors or spatial terms (*in, on, under, beside, in front, behind, next to*, and so on) needed for following directions might be examples. Perhaps the child needs a set of word meanings for getting along better in social situations. One example of this might be the child with autism who uses a lot of echolalia when answering questions. We might want to know whether this child comprehends the meaning of the

question words, since research on echolalia (Prizant & Duchan, 1981) suggests that children with autism often use echoing as a response when they don't know a more appropriate way to answer a question. Another example is verbs, which are known to be especially difficult for children with language disorders (Windfuhr, Faragher, & Conti-Ramsden, 2002), and are not frequently assessed on standardized tests. These kinds of word classes are reasonable targets for criterion-referenced assessment.

Suppose we (or the client's parents or teachers) identify a set of words that are important for a child who scored low on a vocabulary test to know. We can look at knowledge of these words by using a nonstandardized assessment protocol. A variety of games and informal procedures can be used to probe children's knowledge of word meanings. For example, the understanding of question words can be assessed. James (1990) provided an order of acquisition of the understanding of question words. This order is given in Figure 8-4. One means of assessing the comprehension of these question words is to read the child a short, simple story and ask questions about it during the reading (for example, if reading *Chicken Little*, the clinician might read the first page, where Chicken Little tries to tell her friends the sky was falling, then ask, "What was falling?"). We would use this procedure to avoid testing memory rather than the question words of interest. The clinician can choose questions so that each question word is used at least three times. Using a checklist such as the one in Figure 8-5, the clinician can record the child's responses to each trial of each of the question words used in the procedure. This alerts the clinician to the question words the child can answer appropriately and identifies the question words the child has trouble answering accurately. These may be targeted for the intervention program.

Here's another example: the "hiding game." This procedure can be used to assess understanding of spatial prepositions. Normative data come from Boehm (1989). In the hiding game the clinician arranges two identical cups on the floor or table so that one is inverted and one is right side up. The clinician gives the client a raisin to hide from a somewhat backward puppet. The catch is that the child must hide the raisin in the place the clinician indicates.

Question word	Age that normally-developing children response	Number of trials	Number of correct responses
	appropriately (years-months)		
What ...?	2-0	_____	_____
Where ...?	2-6	_____	_____
Who ...?	3-0	_____	_____
Whose ...?	3-0	_____	_____
Why ...?	3-0	_____	_____
How many?	3-0 (response with a number, though not necessarily the right one, is acceptable)	_____	_____
How ...?	3-6	_____	_____
When ...?	4-6 or older	_____	_____

FIGURE 8-4 A checklist for evaluating comprehension of question words. (Adapted from James, S. [1990]. *Normal language acquisition*. Boston, MA: College-Hill Press.)

Spatial preposition	Age that normally-developing children comprehend (years-months)	Number of trials	Number of correct placements
Beside	3-0	_____	_____
In	3-0	_____	_____
In front of	3-0	_____	_____
Next to	3-0	_____	_____
On	3-0	_____	_____
Over	3-0	_____	_____
Out	3-0	_____	_____
Under	3-0	_____	_____
On top	4-0	_____	_____
Between	4-0	_____	_____
Behind	5-0	_____	_____
Below	5-0	_____	_____
Above	6-6	_____	_____

FIGURE 8-5 A checklist for evaluating understanding of spatial terms. (Adapted from Boehm, A. [1989]. *Boehm resource guide for basic concept teaching*. San Antonio, TX: Psychological Corp.)

The clinician then tells the child to hide the raisin in locations such as *in*, *on*, *under*, *beside*, or *next to* a cup or *between* the cups. The child hides the raisin and the puppet then “looks” for it in the place the clinician said to put it. If the puppet finds the raisin where the clinician said it should go, the puppet wins the raisin. However, this puppet is a picky eater and does not like raisins, so he always offers the treat to the client. The game continues until each spatial preposition has been tested three times. Using a checklist such as the one in Figure 8-5, the clinician can assess the level of the child’s understanding of spatial terms and identify those that the child has trouble comprehending. These might be included as intervention targets.

These are just two ideas. Clinicians can come up with a variety of “games” and activities such as these to get more information

Games can be incorporated into informal criterion-referenced assessments.

about a child’s comprehension of certain classes of words. Miller and Paul (1995) provided additional ideas. The point is this: when a child scores poorly on a standardized measure of receptive vocabulary, specific content categories can be probed with informal techniques when necessary. This kind of assessment allows us to evaluate a client’s understanding of meanings that are important in his or her communicative interactions. These meanings can, if found to be problematic, be included as targets of intervention.

Syntax and Morphology

Receptive Syntax and Morphology

Unlike vocabulary, syntax and morphology need to be carefully assessed in each of the receptive and expressive modalities. The reason is this: children commonly produce sentence forms, such as agent-action-object constructions, even when they fail to perform correctly on comprehension tests of these same forms in settings where nonlinguistic cues have been removed (Chapman, 1978; Paul, 2000c). Knowing that a child produces a sentence type does not necessarily mean that the child fully comprehends the same sentence if it is spoken to him in a decontextualized format. We do need, then, to be careful about assessing comprehension and production of syntactic forms separately.

Some writers (Lund & Duchan, 1993; Rees & Shulman, 1978) have raised the question of whether the difference between *contextualized* and *decontextualized* comprehension invalidates the use of standardized tests in this area. In real communicative situations, they argue, it is rarely necessary to get all the information needed for a response from the words and sentences. Many other cues are available, including knowledge of what usually happens in situations (often called “scripts” or “event knowledge”); facial, intonational, and gestural cues; and objects and events in the immediate environment that provide nonlinguistic support, to name a few. Most children can take advantage of all these additional cues to assist their understanding of the words and sentences they hear. But if these cues are removed, a child is likely to do more poorly. This is as true for normally developing preschoolers as it is for children with language problems (Naito & Kikuo, 2004; Paul, Fisher, & Cohen, 1988). Of course, most of our standardized and many of our nonstandardized methods of assessing receptive syntax and morphology use decontextualized settings. Children typically perform more poorly on these than they would if the same forms were used in a more normal communicative context. Is this a bad thing?

As you might guess, the answer would be, “It depends.” It depends on how we interpret the results of the decontextualized assessments and whether we include some contextualized assessments for contrasting information. We can look at the decontextualized results as a window onto how much *linguistic* comprehension a child displays and as a way to identify linguistic forms that can cause problems when few other cues are available. This information is very useful for contrasting with performance on production tasks. It can help us determine whether the child can demonstrate linguistic comprehension for forms he or she is not using at all in speech; whether linguistic comprehension and production are about on par; or whether, as normally developing children do in some stages of development (Chapman & Miller, 1975), the child is producing some forms that he or she does not comprehend in decontextualized formats. Knowing how comprehension contrasts with production can help us to decide whether to focus strictly on production skills in the intervention program or whether activities that foster both comprehension and production—such as focused stimulation and verbal script approaches (see Chapters 3 and 9 for

details)—might be more appropriate. In this way, looking at comprehension skills in decontextualized formats can be useful.

Contrasting this performance not only with production but also with performance in more contextualized activities also can be very informative. Lord (1985) advocated this approach for looking at comprehension skills in children with autism. We believe it can be helpful for evaluating receptive skills in any child at a developing language level who has trouble with decontextualized comprehension. Here's why: if a child can take advantage of the nonlinguistic cues in the environment, he or she is in a good position to benefit from intervention activities, such as child-centered approaches, that provide enriched language carefully matched to the nonlinguistic context. Child-centered activities would be an important component of intervention for such a child. But suppose a client does no better on a contextualized assessment than on a standardized test. Some research (Paul, 1990; Paul, Fisher, & Cohen, 1988) on children with autism and specific language disorders suggests that these children are not as efficient as normally developing preschoolers at integrating information from linguistic and nonlinguistic sources. For clients such as these, approaches that make use of naturalistic nonlinguistic context may provide too complex a mix of cues. These clients may need to have the input scaled down, with very clear, simple connections made between the forms being taught and their meanings. For these clients a less naturalistic, more structured form of input may be needed to increase receptive skills.

The following is a general strategy for assessing syntactic and morphological comprehension at the developing language level:

1. Use a standardized test of receptive syntax and morphology to determine whether deficits exist in this area.
2. If the client performs below the normal range, use criterion-referenced decontextualized procedures to probe forms that appear to be causing trouble.
3. If the client performs poorly on the criterion-referenced assessments, test the same forms in a contextualized format, providing familiar scripts and nonlinguistic contexts; facial, gestural, and intonational cues; language closely tied to objects in the immediate environment; and expected instructions.
 - a. If the child does better in the contextualized format, compare performance on comprehension to production. Target forms and structures that the child comprehends well but does not produce as initial targets for a production approach. Target structures that the child does not comprehend well for child-centered, focused stimulation, or verbal script approaches to work on comprehension and production simultaneously.
 - b. If the child does not do better in the contextualized format, provide more-structured, less-complex input using more hybrid and clinician-directed activities for both comprehension and production.

Criterion-Referenced Methods for Assessing Receptive Syntax and Morphology

Remember that one reason we may need to do criterion-referenced assessment of receptive syntax and morphology is that standardized tests generally provide very few items per structure. This means that, when a child fails, it is hard to know how significant that failure is. Criterion-referenced assessment can help us to decide, for example, whether a child really doesn't know what a structure means or whether he or she just wasn't paying much attention to that particular item on the test. What we want to do on criterion-referenced assessment, then, is to use the standardized

test data to point out structures the child may be having trouble understanding. We can then probe these areas in more depth with criterion-referenced procedures. Let's look at some examples of criterion-referenced methods for assessing understanding of language structure in both contextualized and decontextualized formats.

Decontextualized Formats

Recall from the discussion of comprehension assessment in Chapter 2 that we have several means available to evaluate comprehension, including picture pointing, behavioral compliance, object manipulation, and judgment. We would choose one of these methods based on the child's developmental level and on how well each matches to structures we want to test. It would be fairly easy to use pictures or object manipulation to test understanding of plurals, for example ("Show me the apple/apples."). Behavioral compliance might be a better procedure for testing understanding of *is (verb) ing* constructions ("Show me: the girl is jumping."). Judgment tasks are usually not appropriate for preschoolers.

Just as we could construct games and activities to test receptive vocabulary, we can follow a similar procedure for probing the comprehension of those structures that were identified as possible sources of errors on a standardized test. Sentences containing past and future tense might be one example. Suppose a client missed the past- and future-tense items on a standardized test. We would want to find out whether comprehension of these items is really impaired. We might construct an activity such as the one in [Box 8-2](#).

This is just one example of a method for probing a client's understanding of specific syntactic and morphological forms. Clinicians can devise simple activities such as these for any form on which additional information is needed. Miller and Paul (1995) provided additional activities. Notice that activities such as these, although not standardized, still remove most of the nonlinguistic context and require the child to understand the message from just the words and sentences. We can, as we've seen, contrast performance on decontextualized assessments such as these to performance in more naturalistic comprehension situations. Let's see how.

Assessing Comprehension Strategies

In Chapter 7 we talked about some methods of assessing comprehension and comprehension strategies in children with emerging language. We said it was important to look at what children do when they *don't* understand all the words and sentences in decontextualized activities. If they use strategies such as those used by normally developing children, we can feel more confident that comprehension skills are proceeding along a normal course. Naturalistic approaches such as indirect language stimulation and verbal script therapy will be useful for increasing receptive skills. If, on the other hand, clients are not using typical strategies, we might conclude that they are not able to take advantage of naturalistic communicative cues for comprehending and may need more structured input. The techniques outlined for assessing comprehension strategies at the emerging language stage in Chapter 7 also can be used with children at a developing language level. Here we would be looking for use of strategies such as "child as agent" and "probable events."

Remember that normally developing children at the 2- to 3-year level of comprehension are able to process *agent-action-object* instructions, but also they still rely on a "probable event strategy" for deciding which noun represents the agent and object of action. That is, when presented with a sentence, such as "The mommy feeds the baby," children in the 24- to 36-month period typically

BOX 8-2 Decontextualized Criterion-Referenced Activity for Probing Understanding of Past and Future Tense

Clinician: This is my friend Sammy (display a puppet). Sammy likes to help people, but he doesn't always do it right away. I'll ask Sammy to help me. Sammy, please set the table. In puppet voice: I will set the table. In normal voice: He said he will, but he's not going to do it right now. It's not done yet. I'll try something else. Sammy, please clean your room. Puppet voice: I cleaned my room. Normal voice: Good! I didn't have to wait for that one. Sammy cleaned his room! It's done! Give several additional examples. Then say: You listen now. Listen to Sammy. Then tell me if the job is done.

CLINICIAN	"SAMMY"	CORRECT CLIENT RESPONSE	+/-
Please make the bed.	I will make it.	not done	_____
Please tie your shoe.	I tied it.	done	_____
Please eat your soup.	I will eat it.	not done	_____
Please help me.	I helped you.	done	_____
Please hop to it!	I hopped to it!	done	_____
Please stand still.	I will stand still.	not done	_____
Please stop jumping.	I stopped jumping.	done	_____
Wash your face.	I washed . . .	done	_____
Dry your hands.	I will dry . . .	not done	_____
Please get my hat.	I will get . . .	not done	_____
Please call Dad.	I called Dad.	done	_____
Please go away.	I will go . . .	not done	_____

perform successfully on an object-manipulation task. But if asked to act out the sentence, "The baby feeds the mommy," they are likely to interpret it in the more probable direction (the mommy feeds baby). To test for basic 2- to 3-year-level comprehension skills, then, a series of probable agent-action-object sentences could be presented for a child to act out with some toys. If the child uses a "child-as-agent" strategy by performing designated actions on the named object himself or herself, he or she is demonstrating an 18- to 24-month-level comprehension strategy.

If the child performs correctly on the probable sentences, we can move to the next level of receptive language development. Correct comprehension of both probable and improbable simple sentences is typical of normally developing children at the 3- to 4-year level of comprehension (Chapman, 1978). We can present more agent-action-object sentences for the child to act out, interspersing probable ("The boy pushes the wagon.") and improbable sentences ("The wagon pushes the boy."). If the child performs correctly on both types, we can conclude that linguistic comprehension of agent-action-object sentences is present. If the child gets the probable sentences correct but the improbable ones wrong, we can suspect the use of a probable-event strategy. This client is showing comprehension that is following the normal path. However, if the client does not do any better on the probable than improbable types, we might conclude that the client was not taking advantage of nonlinguistic background information to help in processing sentences. A client like this, who has comprehension deficits, might benefit from more structured input that matches language very clearly and simply to ongoing events. Such a child also might need to develop a fuller set of "scripts" or event expectations to aid in comprehension. Work on play scripts around familiar events, in which the clinician and child re-enact a set of recurring actions over and over, also might be useful. The clinician could include such scripted play as part of every session, carefully choosing simple language forms to match each action in the script and

being careful to repeat each action and its accompanying language exactly during each re-enactment.

Comprehension strategies also can be examined by looking at the errors in the other nonstandardized assessments conducted. For example, if spatial prepositions are assessed, the clinician can look at the child's errors to see whether the child tended to place objects "in" containers when told to put them "on," or "on" surfaces when told to put them "under." These types of errors would be representative of a "probable location strategy" (Chapman, 1978), which is typical of 2- to 3-year-old children. If a child at a 4-year developmental level uses them, they would be evidence of comprehension that is delayed but is nonetheless developing along a normal course.

Information from nonstandardized assessments, then, can be useful not only for probing specific forms and structures, but also for looking at children's strategies for comprehending difficult language. These strategies can give a clinician additional information about how a child deals with language input. Such information can be useful, as we've seen, in developing an intervention program.

Assessing Comprehension in Contextualized Settings

We've talked about using nonstandardized assessment both to probe comprehension of specific forms and to look at strategies for comprehending difficult input. For both these purposes we are looking at comprehension in somewhat contrived situations. If we want to know more about how a child responds to language in a more naturalistic setting, we can set up some communicative situations and observe the child's responses. The reason for doing so, again, is as a contrast to the performance on the decontextualized situations. If a child does just fine on a standardized comprehension test, there is no need to assess comprehension further in a naturalistic setting. However, if the child is not so good at responding to language in formal contexts, it would be nice to know whether he or she does better in more natural ones.

One way to do this is to look at clients' responses to speech addressed to them in ordinary conversation. We can use the sample collected for speech or expressive syntactic analysis. Besides looking at what the child said, we can look at how it related to what was said to the child. We can, for example, compute a percentage of *contingent responses* on the child's part. Contingent responses are those that relate semantically to the previous speaker's utterance. If you say, "Would you like an ice cream?" and I say, "Yeah, I'm in the mood for chocolate," my utterance is clearly related to and contingent upon yours. But if you said, "Would you like an ice cream?" and I answered, "The Kentucky Derby is run in May," the relation between your utterance and mine would not be very clear. According to Bloom, Rocissano, and Hood (1976), children's proportion of contingent utterances rises from less than half at 24 months to more than 75% at 42 months. Looking at contingent responses in spontaneous speech can give us some notion of whether the child is processing the linguistic input well enough to respond contingently.

Lund and Duchan (1993) suggested examining children's language samples to look for a variety of comprehension errors. They suggested, for example, examining responses to questions in the speech sample for understanding of the question words. They suggested further looking at responses to adult requests to determine whether the request was understood. Analyzing spontaneous speech samples for information about comprehension is another way to make use of the conversational samples we collect during the nonstandardized phase of assessment.

Criterion-Referenced Methods for Assessing Productive Syntax and Morphology **Speech Sample Analysis**

We've talked about a variety of ways to use samples of conversational speech to fill out our picture of a client's language skills. Perhaps the most prevalent use of speech-sample analysis is for the purpose of assessing productive syntax and morphology. Costanza-Smith (2010) and Hewitta, Hammer, Yont, and Tomblin (2005) discuss the clinical utility of language sampling. Among other things, spontaneous speech provides the most valid look at how a client uses words and sentences in natural situations. It is more sensitive than standardized tests for identifying preschoolers with clinically diagnosed language delays, more effective for treatment planning and outcome monitoring, and a more valid reflection of the child's use of language in everyday contexts (Costanza-Smith, 2010). So if we really want to know how a client produces language forms, the best way to find out is to take a sample of the use of these forms in real communication.

The first decision we need to make when we do speech sample analysis concerns how we *collect the sample*. Quite a bit of research has focused on how the sampling context affects the quality of language samples. Schmidt and Windsor (1993), for example, showed that there was little difference in MLUs of both normally developing children and those with Down syndrome (DS) when samples were gathered from conversations during structured or unstructured activities. Southwood and Russell (2004) reported that free play yielded more utterances than story generation, but stories yielded longer and more complex sentences, whereas conversation yielded sentences as complex but shorter than those used in stories. But Wagner, Nettelbladt, Shalen, and Nilholm (2000) found that intelligibility and fluency were higher in conversational samples than in narration among preschoolers with language impairments. In addition, children used more complex verb forms in conversation than narration at this age. Sedey, Miolo, and Miller

(1993) demonstrated that the degree of linguistic complexity produced by both normally developing children and those with Down syndrome did not differ in conversations with a parent as opposed to a clinician, although more speech overall and more lexical diversity were found in the parent-child samples. Longhurst and File (1977) showed that more complex language was elicited in conversation, as opposed to picture description. This research suggests that when using a language sample to evaluate expressive syntactic and morphological skills, a language sample based either on a relatively unstructured free-play situation or on a more structured activity with either parent or clinician is an appropriate method at the preschool level, although we will need to consider other contexts for children at higher language levels. Perhaps picture description should be used only for samples collected from unintelligible children and other contexts should be preferred from children who are easier to understand. Costanza-Smith (2010) suggested that a combination of activities within a sampling session may be the best way to gather a complete picture of the child's performance. In any case, children at the level of developing language need some contextual support to give their best performance in speaking situations. For most preschoolers' situations, people, activities, materials, and topics that are familiar will elicit the most representative sample (Owens, 2009). The materials used also can make a difference. O'Brien and Nagle (1987) reported that play with dolls produced more complex language than play with vehicles, for example, in both boys and girls. Table 2-5 gave some suggestions from Miller (1981) for eliciting a representative speech sample from preschoolers.

Both Hubbell (1988) and Owens (2009) emphasized the importance of the adult's interactive style in collecting these samples. They suggested placing few limits on the child's behavior within the interaction, choosing topics of interest and familiar to the child, and attempting to give the child some measure of control over the conversation. These kinds of interactions are most likely to elicit optimal communication from a client with developing language.

How long a sample do we need? Most writers (e.g., Lahey, 1988; Miller, 1981; Nelson, 1998; Price, Hendricks, & Cook, 2010) suggest 50 to 100 utterances. Cole, Mills, and Dale (1989) showed that a 50-utterance sample yields about 80% of the information available in a sample twice as long. Heilman, Nockerts, and Miller (2010) showed that sample length (i.e., 1-min vs. 3-min vs. 7-min cuts) had nearly no effect on measures for syntactic children as a group. They suggest using short samples of conversation as part of a comprehensive assessment used to identify expressive language delay and for progress monitoring in intervention. They caution, however, that analyzing particular *language* features, such as the presence of certain grammatical morphemes; discourse features, and mazes, may require longer samples. Heilmann (2010) suggests that a 50-utterance sample is usually adequate to provide efficient-yet-valid clinical data gathering for preschoolers, and even shorter samples can be used with narrative sample collection. He reports that 50 utterances are typically collected in 4 minutes for preschool children, and that each minute of speech sample takes approximately 5 minutes to transcribe, so that a typical sample from a preschool child can be transcribed in 20 to 30 minutes. He points out that, although this is a considerable amount of time, it is less than it takes to give a standardized test.

Many researchers (e.g., Cole, Mills, & Dale, 1989; Nelson, 1998) have advocated collecting several samples for analysis of productive language, arguing that multiple samples yield more representative information. Cole, Mills, and Dale suggested that

two short samples (say 10 minutes each) taken on two different days would provide a more valid picture of productive language than a single longer sample. Here's our opinion on this issue: language sampling is one of the best methods we have available for establishing productive language baseline function, targeting intervention goals, and evaluating progress in the intervention program. The most important thing about language sampling is to *do it*. If it is possible to collect two or more short samples for analysis, great! The danger arises when we feel we have to collect and analyze more than one sample and therefore decide not to do language sampling at all. If the alternative to collecting multiple samples is not to do any analysis of spontaneous speech, then it is better to take just one sample that is as representative as we can make it. We can, for example, include both a free play and a short narrative or conversational sample within one 20 minute sampling session. Doing an imperfect language sample analysis is better for clinical purposes than not doing any at all.

When we collect a speech sample, we usually want to *record the sample* in some way. This allows us to examine it in more detail than we could if we had to get all the information from it in real time. It lets us go back later and pick up information we may have missed the first time around and also allows us to analyze the same sample for several different purposes on several different passes through it. As discussed in Chapter 2, audio recordings are usually used when speech itself is the focus of the assessment and when there is enough intelligible speech present that other information is not needed to figure out what the client is talking about. Video recording can be used when nonverbal context is necessary to decipher the child's meanings or when nonverbal aspects of communication are of interest. The recorded sample is then transcribed at whatever level is appropriate for the analysis being done. Syntactic analyses require only word-by-word transcriptions of the client's speech, probably with the linguistic context of the other speaker's remarks included. If we plan to do speech sound analysis on the same transcript, this requires phonemic transcriptions and, in some cases, phonetic level information as well. Pragmatic

analysis necessitates some information about the nonlinguistic context and perhaps about paralinguistic cues that accompany the speech.

Several formats are available for transcription. Miller (1981) provided one example, which involves writing each child and adult utterance on a separate line, with one speaker's utterances indented so it is easy to identify visually who is talking. The child and adult utterances are each numbered consecutively; the child's are numbered C1, C2, and so on, the adult's A1, A2, and so on. Using this method, we also provide columns for morpheme counts, nonlinguistic context, and any comments the transcriber wishes to make. Several symbols are used to indicate questionable transcription, unintelligible utterances, pauses within the utterance, and phonetic transcription. These conventions, along with Miller's transcription format, are shown in Figure 8-6.

One of the most important decisions we make when transcribing is how to separate speech into utterances. Since we transcribe the sample with one utterance per line and often compute morpheme length and do syntactic analysis utterance by utterance, making reliable judgments about when an utterance ends is important. Owens (2009) presented a set of rules that can be used for segmenting utterances in transcripts at the developing language phase. These are summarized in Box 8-3.

One way language level is often assessed in a sample of spontaneous speech is by computing MLU in morphemes. Instructions for computing MLU can be found in Box 8-4. Brown (1973) inaugurated this measure as a means of indexing syntactic development and demonstrated that MLU was a much better yardstick of syntactic development than was age. Brown showed that there was lots of variation in the age at which preschoolers achieved certain syntactic skills, but much less variation in the MLU they displayed when each milestone was reached. For example, some children produced adult question forms at age 2, whereas others did not produce them until close to age 4. But no matter how old the children were when they produced adult question forms, their MLU was always around 3 to 3.5. There has been a good deal of research on the validity of MLU as an index of language development over the years (Eisenberg,

BOX 8-3 Rules for Segmenting Utterances in Preschool Speech Samples

1. A sentence is an utterance:
Mommy will go to the store yester . . . tomorrow = 1 utterance.
2. A command is an utterance:
Go home! = 1 utterance.
3. Run-on sentence with *and* should contain no more than one *and* joining clauses. Sentences with more than one *and* should be separated into additional utterances:
We went on the bus and we got to the zoo and we saw lots of animals and we had ice cream =
We went on the bus and we got to the zoo /(and) we saw lots of animals /(and) we had ice cream.
4. Other complex and compound sentences are treated as one utterance:
He was sad because his daddy yelled at him because he broke the cup and spilled the baby's food.
5. Pauses, inhalations, and falling intonation mark the ends of utterances:
Eat (drop in intonation; pause) . . . oatmeal cookie = 2 utterances: Eat. Oatmeal cookie.
Eat (momentary delay, no fall in intonation) . . . oatmeal cookie = 1 utterance: Eat oatmeal cookie.

BOX 8-4 Rules for Computing MLU from a Sample of Spontaneous Speech

1. Segment the child's speech sample into utterances.
2. Transcribe the sample, putting each utterance on a new line.
3. Identify the first 50 consecutive fully intelligible utterances in the transcript. (Eliminate any utterances that are unintelligible or partially unintelligible from the count.)
4. Count the number of morphemes in each utterance, using the following counting rules:
 - a. Count each free morpheme (word) and each bound morpheme or inflection (such as plural *-s*, possessive *'s*, third-person singular *-s*, past-tense *-ed*, present progressive *-ing*, and so on) as one.
 - b. In stuttering or false starts, count each word only once. If a word is repeated for emphasis ("No, no, no!"), count each occurrence of the word.
 - c. Count compound words (*birthday*), proper names (*Mickey Mouse*), and reduplications (*night-night*) as only one morpheme.
 - d. Count irregular past-tense forms (*went*, *saw*, *came*) as one morpheme. If a child overgeneralizes a past-tense form, such as *goed* or *comed*, count this as two.
 - e. Count words with diminutive endings (*doggie*, *toesie*) as one morpheme.
 - f. Count auxiliary verbs (*is*, *are*, *was*, *were*, *have*, *had*, *has*, *will*, *could*, *can*, *would*, *must*, *might*, *shall*, *should*, and others) as one, even if they are contracted (*He's* is two morphemes; *aren't* is two morphemes), except for *can't* and *don't*, which count as one.
5. Add up the total number of morphemes in the sample. Then divide by the total number of utterances (usually 50). The result is the MLU.

Adapted from Brown, R. (1973). *A first language: The early stages*. Cambridge, MA: Harvard University Press; Chapman, R. (1981). Exploring children's communicative intents. In J. Miller (Ed.), *Assessing language production in children*. Needham Heights, MA: Allyn and Bacon.

Fersko, & Lundgren, 2001; Klee, 1992; Lahey, Liebergott, Chesnick, Menyuk, & Adams, 1992; Miller, Freiberg, Rolland, & Reeves, 1992). The current consensus would appear to be that MLU alone should never be used to determine whether a child has a delay in language development (Eisenberg, Fersko, & Lundgren, 2001), but it does have some value as one aspect of the description of a child's language level, especially when combined with other information about language production, such as the number of different words (NDW) in a speech sample (Klee et al., 2004; Leonard & Finneran, 2003). Table 8-2 gives the normal range for MLU for children in the developing language period, based on data from Brown (1973); Miller (1981); Miller, Freiberg, Rolland, and Reeves, (1992); Owens (2009); and Rice et al. (2010).

MLU can be computed from a free speech sample to compare other areas of language development to it. This comparison can be used to determine whether some areas of language development are further behind than MLU would suggest, even when the MLU itself is less than would be expected for developmental level. Although we know that the relationship between MLU and grammatical development is not a simple one (Leonard & Finneran,

2003), knowing a child's MLU can help guide the remaining portions of the analysis. For example, if the MLU is less than 3, we may wish to concentrate on semantic analyses, such as the analysis of semantic relations discussed in Chapter 7 or Lahey's (1988) semantic-syntactic analysis procedure. These methods would identify meanings expressed and the basic forms used to express them. The clinician could use this information to target additional meanings for expression or to encourage the child to express all meanings with the most advanced forms currently in the repertoire before attempting to expand syntactic complexity. If the MLU is between 3 and 4.5, further analysis might focus on basic morphological and syntactic markers in simple sentences, since such forms typically develop during these MLU stages. If MLU is greater than 4.5, complex sentence development might be the primary area of assessment, since basic morphological and syntactic structures are usually mastered at this MLU level and more advanced structures are beginning to emerge.

MLU is also a useful way to chart change in productive language, and Rice et al. (2010) report data substantiating that MLU is a reliable and valid marker of language impairment that can be

TABLE 8-2 Typical Values for MLU (Morphemes) and Number of Different Words (NDW) in Preschool Children

used clinically for benchmarking deficits and documenting intervention outcomes. If we track MLU taken from a free speech sample each semester in an intervention program, we have a valid means of showing change in spontaneous speech in response to our intervention. You might like to try computing an MLU on the short transcript in Box 8-5. (Remember that we ordinarily want to use at least 50 utterances to compute an MLU.) Cover the answers in the morpheme column and try your hand. Then check against the morpheme counts given in Box 8-5. Use the data in Table 8-2 to decide whether the MLU you found is appropriate for a child of this age.

There are some disadvantages to using MLU as a speech sample-analysis procedure, though. First, it is too global, in itself, to highlight areas of syntactic deficit. If only one syntactic analysis can be done on a sample, MLU is probably not the best choice, since it gives too general a picture and does not pinpoint specific targets for intervention. Second, MLU computation requires full transcription of a speech sample—a time-consuming process.

One issue in using speech sample analysis concerns *increasing the efficiency of the sampling and analysis* procedures. Should we compute MLU for every speech sample collected for the purpose of syntactic and morphological analysis? Probably not. Other analysis techniques, given limited clinical time and resources, yield more information relevant to intervention planning. We might do these more detailed analyses for initial assessment purposes. Then we might use MLU to track progress in intervention without doing more detailed analyses, but rather probing for specific forms using elicited production contexts and using MLU changes to show that these forms are generalizing to spontaneous speech. This would be a more economical allocation of clinician effort than computing an MLU for every speech sample we analyze.

Many practicing SLPs say that speech sample analysis is impractical for real clinical situations because of the time it takes to transcribe and analyze the sample. Let us give you our view on this issue. Speech sample analysis is sometimes (though not always) more time consuming than scoring a standardized test, but it

also provides much richer and more valid information. How can we reconcile this conflict? In our opinion, we need to (1) be very judicious about choosing when to do a speech sample and what analyses to perform and (2) learn to do speech sample analyses more quickly and efficiently.

In deciding when to use a speech sample, we should remember that standardized tests are designed to tell whether a child is different from other children. Dawson et al. (2003), for example, showed that the *Structured Photographic Expressive Language Test—3* (SPELT-3) is very sensitive and specific in identifying children with language disorders. For the purposes of initial identification of expressive language deficit, using a valid tool like the SPELT-3 is certainly recommended. Speech sample analysis, on the other hand, is not constructed psychometrically for this purpose. Speech

Computer-assisted methods can increase efficiency in language sample analysis.

C8: They got toys in here? A: Sure. Here are some. . . . Let's look at these.		6
C9: Yeah, cars in blue box. A: Um-hm, there are some cars in the blue box here.		6
C10: I want XXX green car. A: OK, here's the green one.		4
C11: Hey, it went under there! A: Well, go get it.		5
C12: Got it! A: Good. Is it running OK?		2
C13: Yeah, it run good. A: Good. Let's see what else is in here.		4
C14: Look, red car.		3
C15: Donny have red car. A: Yes, Donny's car is red, but it's a lot bigger than this one, isn't it?		4
C16: Yeah, Donny always drive his car too fast. A: He does! How do you know?		8
C17: Daddy say so last time. A: Oh-oh. I better not let you ride in his car again.		5
C18: No, I'll tell him go slow.		7
C19: You seed him last time?		6
C20: He hitted a wall!	[jumps up and down]	5
C21: The cop yelled at him! A: Oh, no!		6

sample analysis should only be done when it has already been established, by means of standardized testing of expressive language, that the child has a productive language deficit.

The efficiency of speech sample analysis can be increased in two ways. The first is to shortcut some of the steps involved in traditional analysis methods. We can, for one thing, do certain parts of the analysis of connected speech in real time, rather than

transcribing the whole sample. The second way is to make use of computer-assisted procedures.

Let's look at the second alternative first. Price, Hendricks, and Cook (2010) provide detailed guidance on incorporating computer-assisted language sampling into clinical practice. They suggest, first, collecting the sample by using either a portable digital recording device or recording directly into a computer,

which for this purpose would require a sound card, an external microphone, and an audio recording software program, such as Audacity (Mazzoni, 2005; <http://audacity.sourceforge.net>), GoldWave (GoldWave Inc., 2001; www.goldwave.com), or QuickTime Pro (www.apple.com/quicktime/pro). Price et al. (2010) provide instructions for using Audacity to record a language sample.

Once the sample is stored as a digital audio file, the next step is to transcribe it for analysis. Although there is not yet software that can automatically convert the audio file to text, there is software that can make transcription easier. Both CLAN (MacWhinney, 2009) and Transcriber (Barras, Geoffrois, Wu, & Liberman, 1998–2008), are free software programs that divide the audio stream in segments/utterances, and allow the clinician to listen to each utterance any number of times while transcribing it without removing the hands from the keyboard. Price et al. (2010) give a detailed description for downloading and using Transcriber software in this way.

Several computer programs have been developed to assist in speech sample analysis. Table 8-3 provides some examples. Long (1999) and Long and Channell (2001) gave detailed descriptions of several of these programs. Once the sample is transcribed, and codes specific to each program are added, the software identifies and counts features from a list of available options that the clinician chooses. The clinician also can insert special codes into the transcription that allow for the identification and counting of items not on the program's existing menu, or that allow the program to perform various pre-programmed analyses on the coded transcripts. Long (2001) showed that computerized analyses were completed faster and with equal accuracy when compared with manual analysis, when coded transcripts were used. Still, the data entry time required to type in transcripts and insert all appropriate codes can be considerable, especially for those just learning the systems.

But emerging methodologies are beginning to take advantage of more powerful software solutions to simplify the clinician's job in performing language sample analysis. Channell and Johnson (1999) reported on a program that uses probability algorithms to automatically tag words within a speech sample as examples

of particular parts of speech, such as nouns, verbs, and pronouns. They found accuracy to range from 60% to 95%. Channell (2003) reported on a fully automated *Developmental Sentence Score* (DSS; Lee, 1974) program in the computerized profiling system, which requires only transcript entry without coding. Channell found that the automated DSS produced overall scores that were highly correlated with manually scored samples, although agreement on particular categories between the automatic and manual analyses was still only 78%. Long and Channell (2001) had reported good agreement between automatic or manual coding for global (normal/not normal) clinical decisions, although Channell's (2003) results suggest that we still have a way to go before obtaining highly accurate descriptions of performance in individual semantic and syntactic categories from uncoded transcript entry, which is necessary in using automated language sample analysis for intervention planning.

Still, with the speed at which technology changes, it probably will not be long before clinicians can rely on "intelligent" software to do a substantial amount of the work involved in clinical language sampling. In addition, advances in automated speech recognition may, before too long, allow us to play an audiosample directly into a computer program that would automatically transcribe it orthographically, so that the clinician would only have to either enter semantic, syntactic, and discourse codes or input the basic transcript into another program that added them automatically and did a prescribed analysis. Figure 8-7 provides an example of a transcript of Jerry's speech as it would be coded in the SALT program (Miller & Chapman, 2008) and analyzed with the standard SALT profile analysis, comparing Jerry's data to that of children of his age in the SALT database.

In the meantime, let's not forget our other option. To analyze morphological and syntactic production, we also can listen to an audiorecorded speech sample, perhaps the same one we collected for speech sound analysis, and analyze it without transcription. Instead of transcribing, Schuele (2010) suggests we could record data gathered from listening onto a worksheet developed from one of the speech-sample analysis procedures we will discuss. We could stop the recording periodically to process the data and listen again to segments about which we

TABLE 8-3 Examples of Computer-Assisted Language Sampling Analysis Software

Procedure	Description
Automated LARSP (Bishop, 1985)	Based on <i>Language Assessment, Remediation, and Sampling Procedure</i> (LARSP; Crystal, Fletcher, & Garman, 1976).
Computerized Profiling (Long & Fey, 2004)	Includes routines for calculating MLU, Conversational Act Profile (Fey, 1986), Developmental Sentence Score (DSS; Lee, 1974), Profile of Semantics-Lexical Forms (Crystal, 1982), Profile of Phonology (Crystal, 1982), narrative analysis, and Type-Token Ratio (TTR) on coded transcripts.
DSS Computer Program (Hixson, 1985)	Computes DSS on coded transcripts.
Lingquest (Mordecai, Palin, & Palmer, 1985)	Computes MLU, TTR on coded transcripts.
Parrot Easy Language Sample Analysis (Weiner, 1988)	Calculates MLU on coded transcripts.
Pye Analysis of Language (PAL; Pye, 1987)	Provides options for analysis categories on coded transcripts.
Systematic Analysis of Language Transcripts (SALT; Miller & Chapman, 2003)	Calculates MLU, NDW, Total Number of Words (TNW), allows user to count words/forms in specific categories and create categories and codes. Includes routines for comparing multiple transcripts.
CHILDES, CHAT and CLAN (MacWhinney, 2009)	Includes a database of transcripts, tutorials on data entry, programs for computer analysis of transcripts, methods for linguistic coding, and systems for linking transcripts to digitized audio and video.

were unsure (this would be especially easy if we had used Transcriber software [Barras et al., 2008] on a digitally recorded sample!). However, we would not need to transcribe the entire sample to record the morphemes and syntactic patterns that we heard. These could simply be recorded on the score sheet as we listened to the recording.

This approach has some disadvantages, of course. We would not have a written transcription to put into a client's file. We might miss some morphemes while we were listening for sentence structures or vice versa. It would not be easy to compute an MLU using such an approach. However, this method would make speech sampling for morphological and syntactic production more practical in

FIGURE 8-7, cont'd B, SALT Analysis of Jerry's transcript; compared with age-matched database sample.

a clinical setting, and this, to us, seems a sufficient justification. The recording could always be transcribed later, if a written record is needed or an MLU calculation becomes necessary. It can be listened to again by another clinician if reliability information is wanted. Furthermore, Furey and Watkins (2002) showed strong positive correlations between online recordings and those obtained from transcription when analyzing verb productions. This analysis suggests that online analysis can be a viable alternative to transcription procedures and can reduce the time required for language analysis. However, we should note that this study supported accuracy in online recording for one relatively focused aspect of language production. This should emphasize to us that when analyzing language data from a recording rather than a transcript we need to focus on just one aspect of the analysis at a time.

Three key elements are involved in being able to do speech-sample analysis without transcription: practice, *practice*, and **practice!** The only way to achieve competence and make speech sampling valid and efficient is to be completely familiar with the procedure you are using, to the point of having it memorized. This way, your brain becomes the computer that does the analysis. What you need to make this method work are a firm and detailed knowledge of the normal stages of syntactic acquisition, complete familiarity with the structures assessed in the procedure that you are using, and an organization of the analysis firmly in mind before you start. There is no way to achieve this level of knowledge and familiarity except by doing a lot of practice analyses.

These two approaches to speech sample analysis—nontranscribed and computerized—save time on the opposite ends of the process. The former allows the clinician to listen for features in the sample without writing down every word the child says. The computerized methods require us to transcribe the sample, but the computer does the searching and counting automatically. Both methods are faster than transcribing and analyzing by hand, but both require the clinician to—again—practice, practice, practice to make the process efficient. Clinicians committed to doing speech sample analysis can choose their weapon. If you like working with computers, by all means review Price et al. (2010), get one of the speech sample analysis packages, and learn to use it. The investment of time will pay off in a greatly enhanced ability to sample and analyze your clients' speech.

Perhaps, though, you are not a “computer nerd.” If you prefer to work with a pencil, devote some time to studying one of the speech-sample analysis methods we'll discuss next. If you choose one procedure and—you guessed it—practice, practice, practice, you can greatly reduce the time it takes to perform the analysis by hand. When you know one procedure well enough, you'll find you don't need to transcribe every sample but will be able to score it directly from your recording. Either way, you will have performed a great service to your clients. You will have learned to make efficient use of the most valid means of assessing a child's productive language.

One more thing: any speech sample analysis procedure requires a fairly elaborated knowledge of English grammar and of normal language development. Hubbell (1988); Justice and Ezell (2002); Quirk, Greenbaum, Leech, and Svartick (1990); and Parker (1986) all supply helpful background information on the basics of English linguistics. Gleason (2001), Haynes and Shulman (1998b), Hoff (2001), Hult and Howard (2002), Miller (1981), and Owens (2009) provide detailed accounts of the acquisition of English syntax and morphology. Owens (2009) and Retherford (2006) provide step-by-step guides to analyzing language transcripts and provide

information on semantic and pragmatic as well as syntactic and morphological procedures. Extensive information on collecting and transcribing samples also is included in Owens (2009), Price et al. (2010), and Retherford (2006). Retherford provides sample transcripts and audio samples for guided practice and feedback that are very useful in developing the expertise necessary to accomplish language sampling efficiently. These sources are useful references for any clinician beginning the process of speech-sample analysis.

Let's look at some of the *speech sample analysis procedures* available for examining spontaneous speech. Hubbell (1988), Lahey (1988), Lund and Duchan (1993), Owens (2009), and Retherford (2006) provided guidelines for analyzing spontaneous speech using informal, descriptive approaches. Crystal, Fletcher, and Garman (1976) and Tyack and Gottsleben (1977) provided somewhat more formalized approaches that allow the clinician to use the analysis to determine presence of disorder and intervention targets. We will give you some more detailed information on the procedures devised by Lee (1974), Miller (1981), and Scarborough (1990). This is not intended as an endorsement of these procedures over the others. They are simply chosen as a sample of some of the more commonly used procedures. Use of *any* speech sampling analysis goes a long way toward making our assessments of children with developing language more valid measures of real communicative skill.

Miller's (1981) Assigning Structural Stage Procedure is a two-step process. The first involves the analysis of Brown's (1973) grammatical morphemes. The second looks at sentence types and structures. Much of the analysis is available in a computer-assisted form, the SALT program. If you do the analysis by hand, you may transcribe the sample and compute MLU from the transcription, then use the transcription for further analyses. As we suggested earlier, for MLUs less than 3, semantic relational analysis or Lahey's (1988) content-form analysis may be most informative. For samples with MLUs between 3 and 4.5, analysis might focus on basic morphological and syntactic markers in simple sentences. For MLUs greater than 4.5, complex-sentence development might be the primary area of assessment. Alternatively, you can do each step of the two-step analysis on a separate pass by listening to the recorded sample without transcribing or computing MLU. [Figures 8-8](#) and [8-9](#) provide sample worksheets to use for each step in the analysis.

Miller has assigned each of Brown's (1973) grammatical morphemes to the stage of syntactic development in which it is acquired (contractible and uncontractible forms of the copula and of the auxiliary *be* have been collapsed in [Figure 8-8](#), so the total number of morphemes examined is 12, not the traditional 14). According to Brown, a morpheme is *acquired* when it is used correctly in 90% of its obligatory contexts. An *obligatory context* (OC) is a place in the sentence that requires the morpheme to make the sentence grammatically correct. “I have two new shoe_” for example, is an obligatory context for the plural morpheme. These stage assignments are based on Brown's stages indexed by MLU, although you do not need to compute MLU to do the analysis. You'll notice that some morphemes are acquired in stages II, III, V, and V+, but none in stage IV. That's because many forms emerge in IV but are not acquired until later (that is, they are not used correctly 90% of the time in stage IV). We'll see these emerging forms when we do the second step of the Assigning Structural Stage Procedure.

To do the morpheme analysis, note when each morpheme is used and also when it is required. This allows us to look at correct

FIGURE 8-8 Worksheet for analyzing grammatical morpheme use.

	irregular 3rd sing. oc r

usage in obligatory context. That's why there is a column for "obligatory context" and one for "realization" on the form in Figure 8-8. As we listen to the sample, we note when a particular morpheme is required in context (with a "+" in the "obligatory context" column, for example). Then in the "realization" column, we put a "+" if a morpheme is used and a "-" if it is not. When we have listened to the whole sample, we count the number of checks in the "obligatory context" column for each morpheme and divide that number into the number of "+"s that appeared in the "realization" column. This would give us the percentage of appearance of each morpheme in obligatory context. We could then use this information to help decide which morphemes should be targeted in the intervention program. Balason and Dollaghan (2002) warn us, however, that even typical preschoolers do not routinely produce multiple examples of obligatory contexts for all of these morphemes in short speech samples. When interpreting data on grammatical morpheme production, we may need to supplement information from free speech samples with data from probes that attempt to elicit the production of morphemes for which obligatory contexts did not appear in a spontaneous sample.

Let's practice what we've been preaching. Take the short transcript in Box 8-5. (Remember, we ordinarily want to use at least 50 utterances to do a grammatical morpheme analysis.) Try doing a grammatical morpheme analysis on it, using a worksheet such as the one in Figure 8-8. You'll find our analysis in Appendix 8-5.

The second step in Miller's procedure involves analysis of sentence structures. Miller's procedure for this part of the analysis draws on research from normal language acquisition. His manual (Miller, 1981) provided normative data in a set of charts. The child's performance is compared with the data in these charts and assigned to the Brown's stage at which normally speaking children typically first use each form. Again, the stages are indexed by MLU, although it is not absolutely necessary to compute MLU to do the analysis. Rather than using an acquisition or mastery criterion, as the grammatical morpheme analysis does, the sentence-structure procedure uses an *emergence* criterion (that is, stage assignment is based on the appearance of just one instance of a structure). The assumption

made is that one or two instances in a relatively brief speech sample indicate that a form is emerging into the repertoire.

Miller's procedure looks at the following five aspects of sentence structure development:

NP: The elaboration of noun phrases (with articles, demonstratives, pronouns, and quantifiers)

VP: The elaboration of verb phrases (with auxiliary verbs, catenatives, copulas, past-tense marking, and subject-verb agreement marking)

NEG: The production of negative sentences

Q: The production of questions (both yes/no and *wh*-)

COMPLEX: The use of complex sentences

Miller (1981) provided explicit instructions for scoring each form examined in the analysis, with definitions and examples of each of the forms included. Figure 8-9 provides a form that can be used in the Assigning Structural Stage Procedure, showing how forms can be assigned to the stage of development at which each typically appears.

To use Figure 8-9 to accomplish Miller's (1981) Assigning Structural Stage Procedure, we would listen again to our recorded speech sample, utterance by utterance, stopping at the end of each utterance to score it in all appropriate categories. Alternatively, we could score each utterance in a transcription, if we did one. Each utterance would be given the highest score possible in each of the areas (columns in Figure 8-9) for which a score could be given.

To score for NP, each utterance is given the highest score possible for each noun phrase (subject, object of the verb, or predicate nominative) it contained. For example, if a client's utterance 1 is "See big girl," this would receive an NP score of Stage II, because a modified noun occurred in object position in the sentence. The number "1" would be written in the NP/Stage II "S" section of the worksheet. If utterance 2 is "That girl," this utterance would be placed at stage I of NP elaboration, since the modified noun occurs alone, not in a sentence context. A "2" would be written in the "S" column of that section of the form. Noun phrases in subject position are obligatory at Brown's Stage IV. Since this is the case, any

Name _____ Developmental level _____ Age _____ Date _____

*Successful use.

†Attempt; incorrect use.

FIGURE 8-9 Form for scoring Miller's (1981) Assigning Structural Stage Procedure. (Based on Miller, J. [1981]. *Assessing language production in children*. Needham Heights, MA: Allyn and Bacon.)

sentence that contained a *two-word* noun phrase *as subject* would be scored as Stage IV, regardless of the type of modification, because Stage IV would be the highest stage assignment that could be given to such a sentence. If the client's third utterance were "That girl run," this utterance would be scored at Stage IV of NP elaboration, and a "3" written in the "S" column of that section of Figure 8-9. Any sentence containing a noun phrase of three or more words (*great big dog, a nice girl*) would be scored at Stage late IV to early V.

Similarly, the verb phrase in each sentence would be given the highest score possible. Utterance 3, "That girl run," which was scored as stage IV of NP elaboration, would be scored in the VP elaboration column at Stage I, since the verb is unmarked. A "3" would be written in the "S" column of "unmarked V" on Figure 8-9. If the client's fourth utterance were "I wanna go," a VP score of Stage II would be given because the catenative *gonna* was used without a noun phrase complement. A "4" would be recorded in the "S" column of "catenative alone w/o NP."

Any sentence containing a negative form would be given the highest “neg” score possible, in addition to whatever scores were appropriate for NP and VP elaboration. If the client’s fifth utterance were, “I won’t stay,” the score would be Stage III, since *won’t* appears at Stage III on the chart. A “5” would be written in the “S” column of that section of Figure 8-9. Each yes/no question would be scored according to whether it was produced with rising intonation only (“You wanna go?”—Stage III) or with an inverted auxiliary verb or *do* (“Do you wanna go?”—Stage IV). *Wh-* questions would be scored according to both the form of the question and the question word used. For example, if the client said, “When you are going?”, he would receive a score of Stage III for the uninverted auxiliary (are going) and Stage IV for the question word *when*.

If any complex sentences, either embedded or conjoined, occur in the transcript, these would be scored in the complex sentence column. Miller (1981) provided detailed descriptions of the types of complex sentences typically seen in the speech of normal preschoolers. The types of embedding the child uses are scored in the complex sentence column. If, for example, the client said, “He’s the one that I played with,” a score of Stage late V would be given for the relative clause (“that I played with”).

Certain conjunctions appear on the worksheet because they are used frequently by normal preschoolers. If these appear in a client’s sample, they can be scored appropriately. If a client says, “I like it because it’s chocolate,” a score of early Stage IV can be given in the complex sentence column for a conjoined sentence, and a score of V+ can be given for the conjunction *because*. You also can note in the Attempt (A) column when forms are unsuccessfully attempted. By this we mean when a context for a form occurs but the correct one does not appear. For example, for utterance No. 3 (*That girl run*), you *also* could put “3” in the “A” column for the VP Stage II (main V marked occurs occasionally), since a marker (third person singular) should have been there. At this point you might like to try doing a sentence-structure analysis on the sample in Box 8-5. (Remember that we ordinarily want to use at least 50 utterances to perform sentence-structure analysis.) Refer to Miller (1981) as you go, if you have the book available. Try using a worksheet such as the one in Figure 8-9 to practice analyzing the sample for sentence structures. Our analysis appears in Appendix 8-6.

Miller’s procedure is descriptive in nature and does not yield a quantitative score. When we have completed both steps in the analysis, we can look across all the categories we have analyzed and identify the stage at which most of the child’s scores are falling. This would be considered the child’s stage of *mastery*. Any forms missing or in error (attempts) below this stage would be high-priority candidates for intervention, taking into account, of course, other considerations that we discussed in Chapter 3. We would then look for forms missing or attempted at the mastery level. These forms, too, would be candidates for consideration as intervention goals.

It’s important to remember, when looking at the results of this and other syntactic analyses, that children with both normal and disordered language usually don’t use structures that all score consistently at one level. Some scatter is expected. When looking for targets of intervention, though, we would want first to address forms that are missing or in error below the current baseline, or mastery level. These make appropriate short-term goals. Forms above the current mastery level would be good guides for choosing structures that could improve the child’s overall level of functioning and move it closer to an age-appropriate level. This strategy

would help to achieve the long-term goal of bringing the client’s communicative skills more in line with developmental level.

Scarborough (1990) presented a norm-referenced extension of Miller’s (1981) procedure called the *Index of Productive Syntax* (IPSyn). The IPSyn uses a “productivity criterion” of two appearances of each structure of interest within a 50- to 100-utterance speech sample. Any structure that appears twice in the sample is considered “productive,” or within the child’s current repertoire. The procedure is efficient in terms of time because only the first two appearances of any structure need to be counted, not the total frequency. The IPSyn orders a broad range of structures in each of Miller’s five categories developmentally, so it is easy to identify emerging language levels. It includes many of the structures examined by Miller, and it adds several that Scarborough’s research has shown to be diagnostic in children’s speech. A sample IPSyn score sheet appears in Figure 8-10.

Although not technically standardized, the IPSyn does provide norm-referenced information from a small sample of preschool children with typical language acquisition. Of course, in general we have already decided that a child has a language disorder before analyzing a speech sample. The IPSyn’s norm-referenced information can be used to track progress in an ongoing intervention program, though, as MLU can. But unlike MLU, an IPSyn score used for tracking also gives detailed information on syntactic structures used. If we can show with an IPSyn score that the child is moving closer or into the normal range on structures that we have targeted in the program, we are in a stronger position to argue for our program’s efficacy. Moreover, the structural information from the procedure can help decide which syntactic goals have been met and which need additional intervention. Long and Fey’s (2004) *Computerized Profiling* contains a software program to accomplish this analysis on entered transcripts.

The IPSyn also can be adapted as a criterion-referenced procedure to look at structures that are productive in a child’s repertoire, to identify levels of emerging language, and to find structures currently missing from the repertoire that can be targeted for intervention. Although the procedures and scoring criteria for accomplishing an IPSyn are too extensive to be given here, clinicians who want to combine norm- and criterion-referenced assessment in speech sampling may want to locate Scarborough’s (1990) paper in *Applied Psycholinguistics* and try the procedure. This method is worth investigating before you decide which speech sample procedure you choose to study in-depth and use in clinical practice.

A third method of speech sample analysis commonly used by clinicians is Lee’s (1974) Developmental Sentence Score (DSS) procedure. Like the IPSyn, the DSS provides both norm- and criterion-referenced information. Hughes, Fey, and Long (1992) argued that, despite the fact that this procedure is close to 40 years old, it is, in their words, “still useful after all these years.” The reasons for its longevity include its relatively large norm-referenced data base (more than 200 children), its well-organized format that enables easy visual inspection of a variety of forms at different developmental levels, and its broad range of structures scored in a way that makes diagnostic interpretation possible. Moreover, recent work has moved toward making automated DSS analysis workable (Channell, 2003).

The DSS procedure looks at eight syntactic categories: indefinite pronouns, personal pronouns, main verbs, secondary (embedded) verbs, negative markers, conjunctions, interrogative reversals, and *wh-* question forms. In each category are eight developmentally ordered levels of complexity, which are awarded scores from one point for the simplest level to eight points for the most complex.

FIGURE 8-10 Index of Productive Syntax (IPSyn) scoresheet. (From Scarborough, H. [1990]. Index of productive syntax. *Applied Psycholinguistics*, 11, 6-7. Reprinted with permission from Cambridge University Press.)

Lee's summary of these levels, categories, and scores appears in Table 8-4. Structures in each of the eight categories are scored by assigning the appropriate number of points to each scorable structure that is present in a complete noun-verb (subject-predicate) utterance in the speech sample. In addition, a "sentence point" is added to the score of each sentence that is completely correct by adult standards. Since the DSS does require 50 complete noun-verb utterances for scoring, it is only appropriate for children whose speech contains primarily full sentences, rather than telegraphic utterances. In general, this would translate to a rule of thumb that the DSS would only be used for children whose MLUs are greater than 3.

Complete scoring instructions for the DSS can be found in Lee (1974). To do this analysis we inspect the speech sample, utterance by utterance, for structures in each of the eight categories and award points for each structure identified, according to the criteria in Table 8-4. For example, if the client said, "Don't you like ice cream?" we would inspect this sentence for structures in each of the eight categories. The *don't* would be scored in the Negative column with 4 points. It also would receive 4 points in the Main Verb column (for *don't like*), as "obligatory do + verb." (It is a peculiarity of the DSS that verbs can receive scores in several of

the eight columns.) *You* would receive one point in the Personal Pronoun column. The sentence also would receive six points in the Interrogative Reversals column for the obligatory reversal of *don't* ("You don't like ice cream."/"Don't you like ice cream?"). It also would earn a sentence point for overall correctness. No points could be scored in the Indefinite Pronoun, Secondary Verb, or *Wh-* Question columns for this sentence. Attempt marks (-) are used to indicate that a structure was tried but produced in error. For example, the sentence "I running" would receive an attempt mark (-) in the Main Verb column. Attempt marks receive no numerical score, but they can be inspected at the end of the analysis for error patterns.

Lively (1984) provided useful tips to improve accuracy and efficiency of DSS scoring. Hughes, Fey, and Long (1992) also provided suggestions for clarifying some ambiguous criteria in Lee's manual and for modifying a few rules to make the procedure more clinically useful. These papers are valuable resources for clinicians who decide to make the DSS the language-analysis procedure they implement in clinical practice. Channell (2003), Channell and Johnson (1999), Hixson (1985), and Long and Channell (2001) discuss computerized scoring programs for the DSS.

TABLE 8-4 The Developmental Sentence Scoring Reweighted Scores

Score	Indefinite Pronouns or Noun Modifiers	Personal Pronouns	Main Verbs	Secondary Verbs
1	<i>It, this, that</i>	1st and 2nd person: <i>I, me, my, mine, you, your(s)</i>	A. Uninflected verb: "I see you." B. Copula, <i>is</i> , or 's: " <i>It's red.</i> " C. Is + verb + ing: " <i>He is running.</i> "	
2		3rd person: <i>he, him, his, she, her, hers</i>	A. -s and ed: <i>plays, played</i> B. Irregular past: <i>ate, saw</i> C. Copula: <i>am, are, was, were</i> D. Auxiliary: <i>am, are, was, were</i>	Five early-developing infinitives: "wanna see" ("want to see") "I'm gonna see." (going to see") "I gotta see." ("got to see") "Lemme [to] see." ("let me [to] see") "Let's [to] play." ("let [us to] play")
3	A. <i>No, some, more, all, lot(s), one(s), two (etc.), other(s), another</i> B. <i>Something, somebody, someone</i>	A. Plurals: <i>we, us, our(s), they, them, their</i> B. <i>These, those</i>		Noncomplementing infinitives: "I stopped to play." "I'm afraid to look." "It's hard to do that."
4	<i>Nothing, nobody, none, no one</i>		A. <i>Can, will, may</i> + verb: <i>may go</i> B. Obligatory <i>do</i> + verb: <i>don't go</i> C. Emphatic <i>do</i> + verb: " <i>I do see.</i> "	Participle, present or past: "I see a boy <i>running.</i> " "I found the toy <i>broken.</i> "
5		Reflexives: <i>myself, yourself, himself, herself, itself, themselves</i>		A. Early infinitival complements with differing subjects in kernels: "I want you to come." "Let him [to] see." B. Later infinitival complements: "I had to go." "I told him to go." "I tried to go." "He ought to go." C. Obligatory deletions: "Make it [to] go." "I'd better [to] go." D. Infinitive with <i>wh</i> -word: "I know what to get." "I know how to do it."
6		A. <i>Wh</i> -pronouns: <i>who, which, whose, whom, what, that, how many, how much</i> : "I know <i>who</i> came." "That's <i>what</i> I said." B. <i>Wh</i> -word + infinitive: "I know <i>what</i> to do." "I know <i>who(m)</i> to take."	A. <i>Could, would, should, might</i> + verb: <i>might come, could be</i> B. Obligatory <i>does, did</i> + verb C. Emphatic <i>does, did</i> + verb	
7	A. <i>Any, anything, anybody, anyone</i> B. <i>Every, everything, everybody, everyone</i> C. <i>Both, few, many, each, several, most, least, much, next, first, last, second (etc.)</i>	(<i>His</i>) <i>own, one, oneself, whichever, whoever, whatever</i> : "Take <i>whatever</i> you like."	A. Passive with <i>get</i> , any tense Passive with <i>be</i> , any tense B. <i>Must, shall</i> + verb: <i>must come</i> C. <i>Have</i> + verb + <i>en</i> : " <i>I've eaten.</i> " D. <i>Have got</i> : " <i>I've got it.</i> "	Passive infinitival complement with <i>get</i> : "I have to <i>get dressed.</i> " "I don't want to <i>get hurt.</i> " With <i>be</i> : "I want to <i>be pulled.</i> " "It's going to <i>be locked.</i> "
8			A. <i>Have been</i> + verb + <i>ing, had been</i> + verb + <i>ing</i> B. Modal + <i>have</i> + verb + <i>en</i> : <i>may have eaten</i> C. Modal + <i>be</i> + verb + <i>ing</i> : <i>could be playing</i> D. Other auxiliary combinations: <i>should have been sleeping</i>	Gerund: " <i>Swinging is fun.</i> " "I like <i>fishing.</i> " "He started <i>laughing.</i> "

Negatives	Conjunctions	Interrogative Reversals	Wh-Questions
<i>It, this, that</i> + copula or auxiliary <i>Is, 's</i> + <i>not</i> : "It's <i>not</i> mine." "This is <i>not</i> a dog." "That is <i>not</i> moving."		Reversal of copula: " <i>Isn't</i> it red?" " <i>Were they</i> here?"	A. <i>Who, what, what</i> + noun: " <i>Who</i> am I?" " <i>What</i> is he eating?" " <i>What</i> book are you reading?" B. <i>Where, how many, how much, what . . . do what . . . for</i> : " <i>Where</i> did it go?" " <i>How much</i> do you want?" " <i>What</i> is he <i>do-ing</i> ?" " <i>What</i> is a hammer <i>for</i> ?"
	And		
<i>Can't, don't</i>		Reversal of auxiliary <i>be</i> : " <i>Is</i> he coming?" " <i>Isn't</i> he coming?" " <i>Was</i> he going?" " <i>Wasn't</i> he going?"	
<i>Isn't, won't</i>	A. <i>But</i> B. <i>So, and so, so that</i> C. <i>Or, if</i>		<i>When, how, how</i> + adjective: " <i>When</i> shall I come?" " <i>How</i> do you do it?" " <i>How big</i> is it?"
	Because	A. Obligatory <i>do, does, did</i> : " <i>Do</i> they run?" " <i>Does</i> it bite?" " <i>Didn't</i> it hurt?" B. Reversal of modal: " <i>Can</i> you play?" " <i>Won't</i> it hurt?" " <i>Shall</i> I sit down?" C. Tag question: "It's fun, <i>isn't it</i> ?" "It isn't fun, <i>is it</i> ?"	
All other negatives: A. Uncontracted negatives: "I <i>can-not</i> go." "He has <i>not</i> gone." B. Pronoun-auxiliary or pronoun-copula contraction: "I'm <i>not</i> coming." "He's <i>not</i> here." C. Auxiliary-negative or copula-negative contraction: "He <i>wasn't</i> going." "He <i>hasn't</i> been seen." "It <i>couldn't</i> be mine." "They <i>aren't</i> big."			<i>Why, what if, how come, how about</i> + gerund: " <i>Why</i> are you crying?" " <i>What if</i> I won't do it?" " <i>How come</i> he is crying?" " <i>How about</i> coming with me?"
	A. <i>Where, when, how, while, whether (or not), till, until, unless, since, before, after, for, as, as</i> + adjective + <i>as, as if, like, that, than</i> : "I know <i>where</i> you are." "Don't come <i>till</i> I call." B. Obligatory deletions: "I run faster <i>than</i> you [run]." "I'm <i>as big</i> as a man is [big]." "It looks <i>like</i> a dog [looks]." C. Elliptical deletions (score 0): "That's <i>why</i> [I took it]." "I know <i>how</i> [I can do it]." D. <i>Wh</i> -words + infinitive: "I know <i>how</i> to do it." "I know <i>where</i> to go."	A. Reversal of auxiliary have: " <i>Has</i> he seen you?" B. Reversal with two or three auxiliaries: " <i>Has</i> he <i>been</i> eating?" " <i>Couldn't</i> he <i>have been</i> crying?" " <i>Wouldn't</i> he <i>have been</i> going?"	<i>Whose, which, which</i> + noun: " <i>Whose</i> cat is that?" " <i>Which</i> book do you want?"

Normative data on DSS scores in relation to age in typically developing children, as presented by Lee, appear in [Figure 8-11](#). To use this graph, we identify the child's age (or developmental level) and read up to the DSS score computed for that child's transcript. If the score falls below the 10th percentile line for that age (or developmental level), we would conclude that the child had a language deficit. We also would be justified in reporting an age-equivalent score, based on the same graph. To find the age equivalent, we would simply read across from the child's DSS score to the 50th percentile line, then read down to determine the age for which that score fell on the 50th percentile. If our client is 5 years, 6 months and earned a DSS score of 5, for example, we would see that a DSS of 5 falls at the 50th percentile for 3-year-olds. So this client's DSS age equivalent would be 3:0. *Remember*, though, that it is only appropriate to report an age-equivalent score if the score falls below the 10th percentile for the child's age. If our 5-year, 6-month-old client got a DSS of 8, we would simply report that this score fell at the 25th percentile for age and was within the normal range.

Like the IPSyn, the DSS can be used as a criterion-referenced procedure, too. Hughes, Fey, and Long (1992) suggested four ways to examine the DSS for goal selection and intervention planning. These are summarized in [Box 8-6](#).

[Figure 8-12](#) provides a worksheet that could be used in scoring a DSS analysis. Why not try using these criteria, along with information from Hughes, Fey, and Long (1992), Lee (1974), and Lively (1984), to score the sample in [Box 8-7](#)? Remember that you need noun-verb utterances to score in the DSS, and in a real clinical sample you would need 50 of them. If you don't find 50 noun-verb utterances in [Box 8-7](#), do the analysis on the ones you find, remembering that you will need 50 to get a valid score from a client. My analysis appears in [Appendix 8-7](#).

Elicited Procedures

One drawback in using speech sampling to assess productive syntax and morphology is that the child may not spontaneously produce all the aspects of language in which we are interested. When talking to an unfamiliar adult, for example, a child may be unlikely to produce questions and negative forms, for pragmatic reasons. If these forms simply do not appear in spontaneous speech, how can we know what the child's skills in these areas are? The advantage of criterion-referenced assessment is that we can combine approaches as needed to give us access to additional information. One strategy for doing a criterion-referenced production assessment would be to collect a sample of spontaneous communication, record and analyze it, and identify any structures or functions of interest that did not appear in the sample, in addition to those that appear to be in error. We could then use the strategy we discussed in Chapter 2. An elicited production procedure could be devised to try to get some evidence about these forms. If the child still failed to "take the bait" in the elicited production activity, direct elicited imitation ("Say, 'He is going.'") might be tried as a last resort.

For example, Loeb, Pye, Redmond, and Richardson (1996) provided a procedure for eliciting verb forms. They argue that verbs are an especially important part of the child's lexicon to evaluate because it is known that children with language disorders have particular troubles in acquiring verbs and in using verbs that are precise and varied (Rice & Bode, 1993). Language samples may fail to show whether the child is able to produce some of these more precise and differentiated verbs, so an elicited probe makes sense as a follow-up to speech sample analysis. Loeb et al. identified a set of verbs of various syntactic types and semantic categories and

developed a task in which to elicit them. Their research showed significant differences between typical 4-year-olds and those with disordered language in the ability to produce specific verbs in the elicitation task. These differences were particularly strong for verbs that were lower in their frequency of use (70% of the low frequency verbs were produced correctly by children with typical development, whereas only 55% were produced correctly by children with language disorders). [Table 8-5](#) presents the contexts used to elicit the low frequency verbs.

Questions are another good example to consider. Suppose a client did not produce any questions in a spontaneous speech sample, but use of negatives and auxiliaries suggested that questions might be a problem. A clinician might want to try a quick question elicitation, just to see what questions looked like. Here, a procedure such as the "shy puppet" activity could be used. The "shy puppet" activity is outlined in [Table 8-6](#). Similar activities could be devised to elicit any form of interest that failed to show up in a sample of spontaneous speech.

Complex sentences are another important area of development during this phase. Eisenberg (2005) suggested an elicitation technique that allows us to assess both the production and understanding of sentences with infinitive clauses, one of the first complex types to emerge. Examples are shown in [Table 8-7](#), and the complete protocol, along with a discussion of the levels of difficulty for the tasks, can be found in Eisenberg's paper.

Lund and Duchan (1993), Miller (1981), Redmond (2003), Rowland and Theakston (2009), and Theakston and Rowland (2009) provided additional examples of procedures for eliciting particular language forms. If the child does not produce the form of interest in the elicited format, the clinician could ask the child to imitate the form directly.

Pragmatic Assessment

Although there are tests designed to assess pragmatic skills in children, a "test" of pragmatics is almost a contradiction in terms. Since pragmatics involves the use of language for real communication, we need to assess it in a more naturalistic context, and this implies using criterion-referenced or informal procedures.

Why do we need to assess pragmatics? In our view, the pragmatic assessment supplies two important pieces of information about our clients. First, it can tell us whether clients are stronger or weaker in pragmatic communication relative to their skills in semantics, syntax, and phonology. Bishop, Chan, Adams, Hartley, and Weir (2000), for example, showed that there is a subset of children with specific language impairments who have pragmatic difficulties over and above their problems with language form and content. Children with autism spectrum disorders (Tager-Flusberg, Paul, & Lord, 2005) and those with nonverbal learning disabilities (Volden, 2004) are additional groups for whom pragmatic skills may be a special difficulty. For children with strong pragmatic skills, the clinician can target language forms in both structured and naturalistic contexts with confidence that, once learned, new skills will be incorporated into the clients' communicative repertoire. For clients who do not effectively use the language they have for communication, clinicians will be less willing to make this assumption. Language goals would be taught first in structured activities. Later, carefully scaffolded activities would work toward getting the child to use new language forms in more varied communicative contexts. The clinician would set up naturalistic situations in which the use of the new forms could be modeled for the

FIGURE 8-11 Age-DSS score relationships. (Reprinted with permission from Lee, L. [1974]. *Developmental sentence analysis* [p. 16]. Evanston, IL: Northwestern University Press.)

BOX 8-6 Suggestions for Using DSS Information for Goal Selection and Intervention Planning

1. Note the frequency of attempt marks for each category. Select a grammatical target that the client is attempting to produce but producing incorrectly.
2. If many low-scoring forms are produced correctly but high-scoring forms are scarce, select forms that are at the level just above those the child is currently producing correctly.
3. Analyze sentences that did not receive a sentence point for patterns of error. If a pattern, such as leaving out articles, is found, target this grammatical class.
4. Examine the frequency of occurrence of forms for each category. Identify infrequent forms at the same level as other forms the child produces consistently and try to increase the frequency of use of the infrequent forms.

Adapted from Hughes, D., Fey, M., & Long, S. (1992). Developmental sentence scoring: Still useful after all these years. *Topics in Language Disorders*, 12, 1-12.

child. Then the clinician would provide opportunities for the child to use the new form in situations similar to the model. Generalization of new forms to conversation cannot be assumed for the poor communicator, and structured generalization activities, such as those discussed in Chapter 3, are especially important.

The second purpose of assessing pragmatic skills is to identify the pragmatic contexts in which new forms should be practiced. If a child has problems with pragmatic functions, we need to teach the language necessary to achieve those functions. Then we need to provide guided practice, through hybrid and child-centered approaches, in using the newly learned forms to accomplish the pragmatic functions with which the child has trouble. A list of the kinds of pragmatic problems often reported in children with language impairments appears in [Table 8-8](#).

There is one more purpose for pragmatic assessment: to identify the particular problems in conversation and interaction faced

by the small group of children for whom pragmatic skills are the only or primary area of deficit. At the preschool level, these children are rare, but a few with diagnoses such as high-functioning autism (see section on ASD, below), nonverbal learning disabilities, or pragmatic language impairment (PLI) may be part of your caseload. For this small group of preschoolers, pragmatic assessment may constitute the main portion of the evaluation.

A variety of procedures have been proposed for looking at pragmatic skills in communicative interactions. O'Neill (2007) provides a parent report measure of pragmatic skills for children 18 to 47 months of age that has well-established psychometric properties and is very useful for identifying pragmatic difficulties in children both with and without other communication disorders. Girolametto (1997) also developed a parent-report measure for profiling pragmatic skills in preschoolers. This measure has demonstrated good internal consistency and test-retest reliability. As

FIGURE 8-12 Sample DSS scoring worksheet.

BOX 8-7 Sample Transcript from a Child Aged 4 Years, 8 Months for DSS Practice

Child (C) 1: I got one for you.	C23: I make something.
Parent (P) : Oh, you got one, OK.	P: What are you going to make, though?
P: What else do I get?	C24: Potatoes.
C2: Got there.	P: Oh I was thinking more of cookies, but that's OK.
P: What's that?	C25: And cookies, cookie.
C3: I can't remember.	C26: That's the bed.
P: Well, what are we going to play?	P: Oh, guess what today is?
C4: These cups.	C27: What?
P: What is this?	P: Today's hockey.
C5: A box to put something in.	C28: Today's hockey?
C6: Oh two, up.	C29: I wanna put that.
C7: Cup two fill up.	P: X fix me something to eat.
P: What did you bake, anything?	P: What are we going to have?
C8: It is.	C30: I'm thinking.
P: What is it?	C31: Dingdong, that's the door.
P: What happened?	C32: Now open it.
C9: I don't spill nothing.	C33: Now shut it.
P: You didn't spill anything, OK.	C34: Oh, do it.
P: What's on the plate?	C35: You know what this is?
C10: These.	P: No, what?
P: Didn't you bake anything for me?	C36: A table.
C11: I did.	C37: This is our lunch.
P: Want to play something else?	C38: A car in the garage.
C12: I wanna play house.	C39: I opened it.
P: You want to play house?	C40: This door opens.
C13: Yeah, I'm gonna do this.	C41: Who did that?
C14: Play with this too.	P: Are you making a mess?
C15: The door.	C42: I gotta fix some.
P: What's in there?	C43: Who's that?
C16: Toys.	P: You drink coffee?
P: Do they have a bed like yours?	C44: In this.
C17: Them don't fit in my bed.	C45: I'm making this.
C18: Too big for my bed.	P: How many kids have you got at your house?
P: Too much stuff on your bed.	C46: Only a baby.
P: Did you bring your dolls down?	P: What's our baby's name?
C19: Brought my doggie.	C47: You tell them.
C20: See.	P: OK, it's Missy.
C21: No play.	C48: Yeah, Missy's her name.
P: You don't want to play?	C49: She's a big girl.
C22: No I does.	C50: She's big and she likes cookies.

part of a family-centered assessment, this measure provides an opportunity to include parental perceptions in the evaluation of young children's conversational ability. The measure appears in [Figure 8-13](#). Girolametto reports that average scores on each of the two scales (responsiveness and assertiveness) of 4.5 or greater should be considered evidence of well-developed pragmatics. Average scores between 3 and 4.4 should be considered as emerging pragmatic competence, whereas those less than 3 should be considered indicative of pragmatic weaknesses.

Many pragmatic assessments involve observation of natural communication. Rice, Sell, and Hadley (1990) developed a method that can be used to assess conversational interactions in a play setting. Prutting and Kirchner's (1983) Pragmatic Protocol is commonly used to assess general pragmatic skills in a global way on the basis of an observation of interaction. The Pragmatic Protocol appears in [Figure 8-14](#). To use it, the clinician observes a child interacting with an adult or peer. The clinician subjectively rates each type of communicative act on the worksheet as either "appropriate" or "inappropriate" on a global basis, taking the entire interaction into account. The resulting data can give a clinician a general idea

of whether the majority of the child's communicative behaviors are adequate. Such an assessment allows us to look specifically at pragmatic behaviors that are inappropriate. These behaviors can be modeled for the client in the course of using real communicative situations as contexts for intervention activities.

Roth and Spekman (1984a, b) also presented a framework for assessing pragmatic skills. They divided pragmatics into three areas: communicative intentions, presupposition, and organization of discourse. They advocated using a conversational interaction between child and adult as a basis for observing the pragmatic skills they identified. [Table 8-9](#) gives an outline of guidelines based on Roth and Spekman (1984a, b) for analyzing a communicative interaction. Again, the results of these observations can be used to identify pragmatic behaviors that can be modeled by the clinician in the communicative interactions used to provide contexts for language intervention.

Creaghead (1984) also suggested a protocol for assessing pragmatic skills in children with developing language, which has come to be known as the "Peanut Butter Protocol." This is a structured interaction in which the clinician attempts to elicit communication

TABLE 8-5 The Verb Elicitation Probe

Target Verb*	Objects	Dialogue
Boil	Pot with water on stove	Prompt: This pan has water in it. We turn on the stove, and now the water's getting really hot. What's the water doing?
Bounce	Rubber ball	(Clinician bounces ball on table) Prompt: What's happening?
Close	Stove/oven door	(Clinician closes oven door) Prompt: What did I do?
Enter	Doll house; toy	(Clinician moves toy toward door of house) Prompt: What is he going to do?
Float	Small boat; pan of water	(Clinician places boat in water) Prompt: What is the boat doing?
Fold	Paper	(Clinician folds paper) Prompt: What am I doing?
Follow	A large and a small toy pig	(Clinician has the small pig follow the large one in a curved path) Prompt: See the pigs? What is this (small one) doing?
Leave	Doll house; toy	(Clinician puts toy in house, and begins moving it toward the outside) Prompt: He's done in his house. What is he doing?
Loosen	String around toy dog; fence	(Clinician ties dog to the fence and says, "This is too tight." Loosens.) Prompt: What did I do to the rope?
Return	Two toy animals	(Clinician has one animal wave goodbye to the other, then begin to move away. The second animal then calls the first back. The first begins to move back toward the first) Prompt: What is this one (first animal) doing?
Roar	Tiger	(Clinician has tiger stand on hind legs and says "Rahr!") Prompt: What did the tiger do?
Smash	Play-Doh	(Clinician smashes a small ball of Play-Doh with a slow motion) Prompt: What did I do?
Sweep	Doll; toy broom	(Clinician puts broom on in doll's hand and has her sweep) Prompt: What is she doing?
Swim	Pan with water; plastic toy	(Clinician puts toy in water and makes swimming motions with it) Prompt: What is he doing?
Tear	"Sticky" note sheet	(Clinician slowly tears sheet in half) Prompt: What am I doing?
Wind	Yoyo	(Clinician winds string around yoyo) Prompt: What am I doing?

*Verbs are alphabetized here but should be presented in random order.

Adapted from Loeb, D., Pye, C., Redmond, S., & Richardson, L. (1996). Eliciting verbs from children with specific language impairment. *American Journal of Speech-Language Pathology*, 5, 17-30.

from the child, then notes whether the child rises to the communicative "bait." In addition, it looks at the form of the child's communication. The results of the "Peanut Butter Protocol," like those of the other two examples, can be used to identify communicative acts that the clinician can model for the client in the course of interactions throughout the intervention program. A worksheet based on Craghead's "Peanut Butter Protocol" appears in Table 8-10.

Numerous other suggestions for assessing pragmatic skills in the developing language phase are available in the literature. Some useful sources are Brinton and Fujiki (1989), Chapman (1981), Lund and Duchan (1993), MacDonald and Carroll (1992), and Shipley and MacAfee (2004). Owens (2009) and Paul (2005), for example, suggested the following categories of analysis to be considered when examining conversational skills in preschoolers:

- *Social vs. nonsocial*: proportion of utterances directed to the listener, rather than self-directed.
- *Topic initiation*: the proportion of new topics introduced by the child rather than the adults.
- *Topic appropriateness*: the proportion of topics that are appropriate to the interpersonal context.
- *Turns/topic*: the number of turns in which the child can maintain a topic.
- *Discourse management*: the number of times the child interrupts another speaker or fails to take a turn appropriately.
- *Contingency*: the proportion of the child's utterances that relate to or are contingent on the previous speaker's remark.

One additional area of pragmatic assessment to consider, particularly for children near the end of the preschool period, is discourse

comprehension, the ability to understand a connected text, such as a story. Skarakis-Doyle, Dempsey, and Lee (2008) showed that the ability to retell and recall events from stories discriminated preschoolers with language impairments from those without them. This assessment is especially relevant for identifying children at risk for literacy difficulties, such as children with delays that persist after age four, those with significant speech sound delays, and those with family histories of learning disabilities. For these children especially, discourse comprehension assessment can help to identify those who are likely to need support in the primary grades for developing the oral language comprehension skills that will serve as a strong basis for the acquisition of reading comprehension. Examples of the kinds of items that can be used in this assessment appear in Box 8-8. These kinds of items can be constructed for a simple story book the clinician chooses to use. Although this measure cannot be considered standardized, data from Skarakis-Doyle et al. suggest that children who correctly respond to less than 50% of 6 or more items presented in each of the three tasks (Joint Retell, Detection, and Comprehension Questions) are performing significantly below their 3- to 5-year-old peers, and should be considered at risk, particularly for reading comprehension difficulties.

The most important thing to remember about assessing pragmatics in the developing language phase is that we want to get a picture of whether clients' pragmatic communication skills are better, worse, or equal to their semantic and syntactic abilities. This information helps us choose methods of intervention. Second, we want to know which specific communicative functions need the kind of guided practice we can provide in a carefully thought-out intervention program.

TABLE 8-6 The “Shy Puppet” Activity for Eliciting Questions

Materials: Two puppets.

Procedure: Give the client one puppet and keep the other. Tell the client, “Your puppet Shyster is shy. He wants to ask my puppet Sally some questions, but he’s so shy he can’t think of what to say. I’ll help him. I’ll tell you what he would like to ask, and you make him ask Sally the question. Try this one. Shyster, ask Sally what she likes to eat.” After the client asks the question, provide an answer from Sally.

Scoring: Use the worksheet below to score the client’s question productions. A sample question for each question type is provided. Give at least three opportunities for the client to produce each question type, but randomize the order in which the question types are elicited.

Question Type	Example	Client Production		
		No Response	Correct Question Form	Other (Transcribe)
Yes/no	Ask whether she likes ice cream.	_____	_____	_____
		_____	_____	_____
What . . . ?	Ask what she’s doing.	_____	_____	_____
		_____	_____	_____
Where . . . ?	Ask where she lives.	_____	_____	_____
		_____	_____	_____
Who . . . ?	Ask who she plays with.	_____	_____	_____
		_____	_____	_____
Whose . . . ?	Ask whose toys she wants.	_____	_____	_____
		_____	_____	_____
Why . . . ?	Ask why she’s sad.	_____	_____	_____
		_____	_____	_____
How many . . . ?	Ask how many sisters she has.	_____	_____	_____
		_____	_____	_____
How . . . ?	Ask how she plays checkers.	_____	_____	_____
		_____	_____	_____
When . . . ?	Ask when she is going home.	_____	_____	_____
		_____	_____	_____

TABLE 8-7 Examples of Elicitation Activities for Infinitive Verb Clause Production and Comprehension

Level/Sample Verb	Materials	Set-Up	Action/Dialogue	Production Target	Acting Out Target
1: want (same subject)	Materials: “Barney” “Baby Bop” dolls w/ moveable arms	Barney sitting; Baby Bop standing, facing him	“Barney and Baby Bop are playing school; Barney is the teacher. Baby Bop says to Barney, ‘Can I lie down?’ Baby Bop wants . . . ? You finish the story. Baby Bop . . . ? Now show me.”	Baby Bop wants to lie down.	Makes Baby Bop lie down.
2a: ask	Materials: Barney” “Baby Bop” dolls w/ moveable arms; toy chair	Barney standing next to chair; Baby Bop, facing him	“This is Barney’s chair. Baby Bop says to Barney, ‘Can you sit in the chair?’ Baby Bop asks . . . ? You finish the story. Baby Bop . . . ? Now show me.”	Baby Bop asks Barney to sit in the chair.	Sits Baby Bop in chair.
2b: want (different subject)	Materials: “Barney” “Baby Bop” dolls w/ moveable arms; toy pool	Barney standing next to pool; Baby Bop in pool	“Baby Bop is swimming in the pool. She says to Barney, ‘C’mon, Barney. You swim, too!’ Baby Bop wants . . . ? You finish the story. Baby Bop . . . ? Now show me.”	Baby Bop wants Barney to swim.	Puts Barney in pool.

TABLE 8-8 A Profile of Pragmatic Skills of Children with Language Disorders

Communicative Function	Linguistic Forms Used
Request	Less likely to be grammatically complete. Fewer indirect forms used.
Comment	Less flexibility in choice of form. Less frequent than in typical populations.
Presupposition	May be stereotypic in form. May have difficulty judging what listeners want/need to know.
Turn-taking	Marking depends more on pronouns than does that of normal speakers. More inadequate forms used in relating to preceding discourse. Turns are shorter in length and involve less speech directed to others. Utterances are less adjacent than those of same-age mates (i.e., children with language disorders take longer to follow up the previous speaker's remark with a turn of their own).
Respond	Children with language disorders are less assertive about gaining turns. Responses are variable; children with language disorders do not always provide a conversationally obligated response; do not consistently compensate for verbal limitations by using nonverbal responses. Responses to requests for clarification are less focused on the informational needs of the requester. Responses to other types of speech acts are more likely to be unrelated or inappropriate. Responses are frequently incomplete, incorrect, unresponsive to interlocutor's intent, or pragmatically inappropriate.
Speech style adjustments and register variation	Speech style adjustments are made (e.g., for younger speakers). Modifications reflect fewer questions about listeners' internal states. Adjustments of utterance length and complexity are less finely "tuned" to the needs of the listener.

Questions designed to accompany storybooks can be used to assess discourse comprehension.

CONSIDERATIONS FOR THE OLDER CLIENTS WITH SEVERE DISABILITIES AND THOSE WITH ASD AT THE DEVELOPING LANGUAGE STAGE

Older Students with Severe Disabilities Who Function at the Developing Language Level

Some children at developing language levels may be older than preschool age. These older, more severely impaired clients, who may have multiple handicaps, have probably been involved in intervention for some time. Extensive assessment data may be on

file, so assessment need not start from scratch. These clients will probably already be identified as eligible for services. There may be a question, though, about their eligibility specifically for language services, particularly if nonverbal and verbal skills are more or less on par. Here the clinician may want to advocate, not necessarily for direct clinical service to the client, but for consultative or collaborative services to increase the client's access and opportunity (Beukelman & Mirenda, 1998) for participating to as great a degree as possible in mainstream activities with chronological age-mates. Increasing opportunities may involve changing policies that provide for separate settings for individuals with disabilities or educating the professionals in new knowledge and skills to enable the inclusion of these students in integrated settings. Increasing access consists of both providing students with compensatory skills, including assistive technology, and adapting the environment to remove barriers to their participation.

Many advocates for the disabled (e.g., Calculator, 1994a, b; Lipsky & Gartner, 1997) see full inclusion in regular education as the goal for all students with disabilities. This approach would suggest, in addition to assessing client skills, assessing the mainstream environment in which the student is to be placed and identifying the demands it will make on the student. The clinician might, for example, observe a second-grade classroom language arts activity to determine what the activity requires of a multiply handicapped 7-year-old functioning at a developing language level. The clinician's role would then be to prepare the student to participate in the activity with whatever resources he or she has available (from producing three-word sentences to using an augmentative or alternative communication [AAC] device). Our role also would include work with the classroom teacher to develop strategies that allow the child's contribution to be invited and rewarded. In this type of enterprise, very little, if any, standardized testing will be needed. Criterion-referenced assessment and behavioral

Instructions

The purpose of this questionnaire is to find out how your child participates in conversations, and what problems, if any, he/she has. By conversation, we mean how your child is able to start conversations, take turns, give information that is on topic, ask questions, and answer questions.

Please use the following scale to rate each statement.

1	2	3	4	5
Never	Almost Never	Sometimes	Often	Always

Throughout this questionnaire, we use the words “ask” or “tell” to describe what your child does in conversation. Since children do communicate nonverbally, please interpret “ask” and “tell” to include gestures, as well as words, phrases, or sentences.

Responsiveness items

1	2	3	4	5	1. If I offer my child a choice of two things that he/she likes, my child tells me which one he/she wants.
1	2	3	4	5	2. If my child knows the name of something he/she tells me the name when I ask.
1	2	3	4	5	3. When I ask a question, my child answers.
1	2	3	4	5	4. If I ask my child to repeat something I haven't understood, he/she does.
1	2	3	4	5	5. In a conversation, my child stays on topic for two or more turns.
1	2	3	4	5	6. My child's responses follow what I am talking about.
1	2	3	4	5	7. My child's answers are connected to what I asked.
1	2	3	4	5	8. My child's sounds/gestures/words match my topic of conversation with him/her.
1	2	3	4	5	9. When I don't understand, my child keeps on trying to get his/her message across.
1	2	3	4	5	10. When I ask my child a question to check what he/she means, he/she answers me.

Assertiveness items

1	2	3	4	5	1. When something new or unusual happens, my child asks about it.
1	2	3	4	5	2. My child asks questions (using sounds/gestures/words).
1	2	3	4	5	3. When my child doesn't know the name of something we are both looking at, he/she asks me what it is.
1	2	3	4	5	4. If I am holding something my child wants, he/she asks for it.
1	2	3	4	5	5. When we are playing a fun game (e.g., tickling) and I suddenly stop, my child asks me for more.
1	2	3	4	5	6. My child asks for help when he/she can't do something and I am nearby.
1	2	3	4	5	7. My child asks me for help when he/she wants something that is out of reach.
1	2	3	4	5	8. When I say something to my child that is not a question, he/she responds.
1	2	3	4	5	9. My child comes to me to start a game or activity that we have done before.
1	2	3	4	5	10. My child starts a conversation with me during familiar routines.
1	2	3	4	5	11. My child tells me when he/she wants to change an activity.
1	2	3	4	5	12. My child asks me to join in his/her play or game.
1	2	3	4	5	13. My child comes to me to tell me about things that interest him/her.
1	2	3	4	5	14. When we are together, my child gets a game going that we have done before.
1	2	3	4	5	15. When we're playing together, my child suggests different play ideas.

Mean score for responsive items (total points/10) _____

Mean score for assertiveness items (total points/15) _____

NOTE: For a copy of the scale for parental use, please contact the author.

FIGURE 8-13 Responsiveness and assertiveness in conversational skills rating scale. (Reprinted with permission from Girolametto, L. [1997]. observation, including observation in the classroom and ecological assessment, will probably be our primary assessment tools. One instrument that may be helpful in this enterprise is the *Functional Communication Profile Revised* (Kleiman, 2003). This tool provides checklists for evaluation of communication skills. An alternative method is the *Triple C Checklist* (Iacono, West, Bloomberg, & Johnson, 2009), designed to assess communication skills in individuals with severe disabilities and emerging language (available at www.scopevic.org.au/index.php/yiiCart/frontend/product/product/path/1_3/id/4).

Clinicians can rate students' current level of functional communication using tools like these, then use these measures as baselines for tracking changes in communicative function as a result of the intervention provided. Figure 8-15 provides a checklist for expressive language adapted from Kleiman (2003), as an example of this type of measure.

School-aged children with severe disorders may continue to function at developing language levels.

Name: _____		Date: _____	
Communicative setting observed: _____		Communicative partner's relationship: _____	
Communicative act	Appropriate	Inappropriate	No opportunity to observe
Utterance act			
A. Verbal or paralinguistic			
1. Intelligibility			
2. Vocal intensity			
3. Voice quality			
4. Prosody			
5. Fluency			
B. Nonverbal			
1. Physical proximity			
2. Physical contacts			
3. Body posture			
4. Foot or leg movements			
5. Hand or arm movements			
6. Gestures			
7. Facial expression			
8. Eye gaze

TABLE 8-9 Suggestions for Assessing Pragmatics

Area Assessed	Suggested Activity
COMMUNICATIVE INTENTIONS	
Expression	Communicative temptations (see Chapters 6 and 7).
comprehension	Have client "bathe" and "dress" doll; give indirect request forms of instructions ("Why don't you wash her face?" "Could you put on her hat?"). Record client responses as compliant or noncompliant.
Presupposition	Barrier games (referential communication) in which partners cannot see each others' referents: client must encode adequate information for partner to identify referents. Extended discourse: Look at use of pronouns, articles, ellipsis, and conjunctions in tasks such as describing how to play a game. Picture description: Show client a picture and ask for description. Then show a picture that is just the same except for one obvious detail. Client's description of second picture should take into account information presupposed in first; e.g., [picture 1] "The dog is running," [picture 2] "He's eating."
Social organization of discourse	Analyze turn-taking; topic maintenance; and conversational initiation, termination, and repair in the referential communication task used to assess presupposition. Role-play situations in which client needs to initiate conversation (e.g., asking for directions, asking for help in a store). Feign misunderstanding in conversation to assess client's ability to make repairs. Use unclear clinician messages to assess client's ability to request clarification.

Adapted from Roth, F., & Speckman, N. (1984a). Assessing the pragmatic abilities of children: Part 1. Organizational framework and assessment parameters. (1984b); Part 2. Guidelines, considerations, and specific evaluation procedures. *Journal of Speech and Hearing Disorders*, 49, 2-11 (Part 1); 12-17 (Part 2).

Older, severely impaired clients may never complete the developmental sequence of language acquisition, even if speech is their primary mode of communication. This fact also argues for the provision of consultative or collaborative services, with the goal of meeting the communicative needs of the important environments in which these students function. Three considerations are especially important in designing assessments that work toward this goal: assessing need for augmentative and alternative communication, using chronologically age-appropriate materials, and evaluating functional communicative needs.

Our first consideration for a child with limited language should address *augmentative and alternative modalities*. We've talked already about the importance of considering AAC systems for children with severe communication disorders. For some older children still functioning at emerging language levels, AAC may

not yet have been tried. If it has not, we may want to consider using some of the assessment techniques we talked about in Chapters 6 and 7 to evaluate the child's need for an AAC system. If the child is obviously frustrated with his or her current level of communicative ability, produces speech that is severely unintelligible, or spontaneously uses gestures or other means to augment speech, a trial of AAC, with assessment to identify the most appropriate system, is certainly warranted.

Second, when we do criterion-referenced or observational assessments for the older, severely impaired client, we want to use situations and props that are *chronologically age appropriate*. We would not use dolls and toys to evaluate adolescents, even if they appear to function at the preschool level of language and cognition. We would want to use materials from the clients' occupational training program or objects that they are learning to use from

TABLE 8-10 Worksheet for Pragmatic Assessment Based on Creaghead's "Peanut Butter Protocol"

Context	Expected Pragmatic Act	Child Behavior		
		No Response	Appropriate Response	Other (Transcribe or Describe)
Child enters room.	Greeting	_____	_____	_____
Have cookies and crackers in view, but out of reach.	Requests object	_____	_____	_____
Give child tightly closed jar with cookies in it.	Requests action	_____	_____	_____
Ask, "How do you think we can get the jar open?"	Hypothesizing	_____	_____	_____
Say, "Do you want (mumble)?"	Request clarification	_____	_____	_____
Ask whether child wants peanut butter or jelly on the cracker.	Makes choice	_____	_____	_____
Hand child the opposite of what he or she chose.	Denial	_____	_____	_____
Put the peanut butter and jelly on the table. Ask, "What are we going to do now?"	Predicts	_____	_____	_____
Tell the child to put peanut butter or jelly on the cracker.	Request object (knife)	_____	_____	_____
Tell child to get knife, which is out of sight.	Requests information	_____	_____	_____
Put peanut butter or jelly on cracker. Eat it. Get out an extra large toothbrush and brush teeth.	Comments on object	_____	_____	_____
Converse with child. During this, pull a hidden string so that a doll falls off the table.	Comments on action	_____	_____	_____

self-care and daily-living activities or from leisure activities in which they like to engage. We might, for example, assess use of basic subject-verb-object sentences or use of *verb* + *particle* by asking a client to tell what is done in each step as he or she makes the bed ("I pull up the sheet. I pull up the blanket. I pull up the spread. I put on the pillow. I tuck in the spread.").

Our third consideration is the *functional efficacy of communication*. What do our older, severely impaired clients need to get done, and how well do current communication skills enable them to do it? One way to address this problem is to develop an *ecological inventory*. An ecological inventory allows us to assess the needs of particular *environments* in which the person must function, rather than the client's communication skills. The ecological inventory

lets us ask the question, "What does this client need to be able to communicate successfully in this environment?" The assessment then identifies those needs, and the necessary communicative behaviors become the targets of our intervention. These behaviors may not be the next ones in the developmental sequence for this client. However, when clients are severely impaired and we know that they will probably never complete that sequence, the primary goal of intervention is to allow them to function as independently as possible within the world in which they live. For example, our developmental model tells us to follow the normal sequence of language acquisition as a curriculum guide for targeting goals. We know that the normal sequence suggests that we would not teach reading to a child with a mental age less than 5 years or to one who

BOX 8-8 Examples from Skarakis-Doyle et al. (2008) Discourse Comprehension Task**SPLISH SPLASH STORY STIMULI (SKARAKIS-DOYLE & WOOTTON, 1995)**

One day a little girl named Sarah made very messy mud-pies in the backyard. Sarah's mom took one look at her and said, "Splish, splash, Sarah needs a bath. Mommy says you're dirty and she can't have that."

So Mom carried Sarah upstairs to the bathroom. Then she filled the bathtub with water and helped Sarah take off her dirty clothes. But Sarah said, "Mommy, I just can't have a bath. First, I must test the water."

JOINT STORY RETELL TASK STIMULI

One day a little girl named Sarah made very messy mud-pies in the back yard. Sarah's mother took one look at her, and said, "_____." (**Splish splash Sarah needs a bath, Mommy says you're dirty and she can't have that**)

So mom carried Sarah upstairs to the bathroom and filled the bathtub with water.

"I must test the water," said _____. (**Sarah**)

So she _____ (**put**) her big toe into the bathtub and said, "Oh Mommy, the water's too cold. The water must be nice and warm."

EXPECTANCY VIOLATION DETECTION TASK STIMULI

One day a little **frog** named Sarah made very messy mud-pies in the backyard. Sarah's mom took one look at her and said, "Splish, splash, Sarah needs a bath. Mommy says you're dirty and she can't have that."

So mom carried Sarah upstairs to the bathroom. Then she filled the bathtub with water and helped Sarah **put on** all her dirty clothes. But Sarah said, "Oh, Mommy I just can't have a bath. First I must test the water."

CONTENT AND GIST COMPREHENSION QUESTIONS

What did Sarah's mother say when she saw Sarah in the backyard? (**Splish Splash, Sarah needs a bath . . .**)

Who wanted to check the bath water? (**the little girl/Sarah**)

In the story, why did Sarah keep starting to leave the bathroom? (**she didn't want a bath/she wanted to play**)

Used with permission from Skarakis-Doyle, E., Dempsey, L., & Lee, C. (2008). Identifying language comprehension impairment in preschool children. *Language Speech and Hearing Services in Schools, 39*(1), 54-65.

had not mastered Brown's stage V of language development. But suppose an adolescent client with linguistic skills in the developing language phase had an opportunity for a paying job unloading boxes from trucks at a warehouse that required him to read some words on the warehouse shelves that indicated where certain boxes were to be placed. Should we deny the client this job because he is not developmentally ready to read? Most of us would like to help enable the client to take this job. To remove barriers to our client's ability to take advantage of this opportunity, we can use focused behavioral interventions to teach the limited amount of reading the client needs, even if he or she may not appear "ready" to read with regard to developmental level.

To compile an ecological inventory, McCormick and Goldman (1984) suggested looking at the major domains in which clients function—for example, domestic, occupational, recreational, and general community—and assessing the communicative needs of each of these settings. Do clients need to ask for help in turning on the TV in the group home? Do they have to tell their supervisor they need to use the restroom at work? Do they need to ask for a locker key at the pool at the YMCA? These needs can be identified by the ecological inventory and targeted in the intervention program.

The ecological inventory can be assembled in two ways. We can "shadow" clients for a typical day, going through each of their activities with them and noting the communicative demands of the situation. Alternatively, we can interview adults familiar with each of the major domains of the client's functioning and compile a list of the communicative needs these adults identify. Parents, of course, are important sources of information in putting this inventory together.

A more structured approach to developing ecological inventories was presented by Rowland and Schweigert (1993). They devised the *Analyzing the Communication Environment (ACE)* as a tool to guide clinicians in establishing these inventories. To use the

ACE, a clinician observes one activity on at least two occasions, starting when the student makes a transition from a previous activity and ending when the activity is completed. The instrument examines six aspects of communication: the activity itself, the communication system the student uses in the activity, the way adults interact with the student in the activity, group dynamics (in group activities), the materials available in the activity, and the specific opportunities for communication that the activity affords. Under each of these aspects, the clinician considers a list of behavior statements given in the ACE and decides whether the behavior is present and whether a change in the behavior is needed. A few examples of the behaviors examined in the ACE are given in Table 8-11, just to give a flavor for the instrument. The ACE also provides a video with example interactions and accompanying text discussing these examples and showing how each would be scored. Once needed changes are identified, the ACE also provides helpful suggestions for making the changes. These suggestions include both targeting the client's behavior and modifying the interactive environment to facilitate functional communicative success for the client. Other structured instruments for compiling ecological inventories also are available, such as McCarthy et al.'s (1998) *Communication Supports Checklist*.

Cascella and McNamara (2004) present an additional approach. They advocate that the clinician develop an individualized "communication profile" for each student, based on in-depth observation and interviews with caregivers and teachers, which lists the forms and functions the student currently uses for communication. These can include conventional forms, such as vocalizations and gestures, as well as idiosyncratic forms, such as body postures. An ecological inventory is then completed that assesses the environments in which the student must function and outlines typical discourse structures, communication expectations, and opportunities.

FIGURE 8-15 Expressive language scale of *Functional Communication Profile—Revised*. (Adapted from Kleiman, L. [2003]. *Functional Communication Profile—Revised*. East Moline, IL: Linguisticsystems.)

Language used in home _____			
Verbal status:		☐ Nonverbal	☐ Verbal
Highest expressive language level:			
☐ Vocalizations	☐ Single words	☐ Phrases	☐ Sentences
☐ Conversation	☐ N/a		
Methods of communication (Check all that apply):			
☐ Sounds	☐ Speech	☐ Signing	☐ Drawing
☐ Spelling	☐ Facial expression	☐ Gaze	☐ Nods
☐ Gestures	☐ Actions	☐ Pointing	☐ Object manipulation
☐ Manipulates others	☐ Photo book	☐ Picture book/board	
☐ Word book/board	☐ Computer with pictures	☐ Computer with word prediction	
Functions of communication:			
☐ Basic needs	☐ Routines	☐ Preferences	☐ Interests
☐ Emotions	☐ Experiences	☐ Concerns	☐ Opinions
☐ Aspirations	☐ Humor	☐ Ideas	☐ Current events
☐ None	☐ Physical feelings	☐ Social exchanges	

Finally, the educational team meets to develop a support plan focused on enabling the child to use the communication strategies he or she has to meet the expectations of the classroom and other daily routines. The team's job is then to create additional communication opportunities to allow the student to use, expand, and diversify communicative acts. For example, if the team knows that a student's current communication profile includes tilting her head to the left when she needs to take a break from working, her job coach can acknowledge this communication ("I see you're tired") and encourage the student to express her need in a more conventional way that meets the expectations of the setting ("At work we need to let people know when we are stopping. Let's go to your supervisor and use our sign for 'stop.'").

The main point to remember about assessment of functional communication for students with severe-to-profound disorders is that we need not only to assess our clients' ability to communicate, but also the demands of the environment in which they function. An important part of our role for these clients is to help achieve a better match between the student's communicative ability and the

expectations of their environments in order to create more opportunities for their communication to succeed in accomplishing their interpersonal goals.

Children with ASD

For preschoolers with ASD who function in the preverbal or emerging language stage, assessments described in Chapter 7 will be appropriate, but for those who are talking in multiword utterances, a few special considerations are in order. Recent evidence (e.g., Rogers et al., 2006; Rogers & Dawson, 2010) tells us that, unlike 15 or 20 years ago when many preschoolers with ASD did not produce functional spoken language, 70% to 80% of preschoolers with ASD today use speech as their primary means of communication. This is good news. Still, it is important to remember that just because a child has ASD does NOT mean he or she can't have speech or language impairments, too. In fact, quite a bit of recent research (e.g., Lindgren et al., 2009; Tager-Flusberg & Joseph, 2003) has shown that there are at least two patterns of language

TABLE 8-11 Example Items from Rowland and Schwiebert's ACE

	Check if Observed	Target for Change
A. ACTIVITY		
The instructional demands of the activity do not frustrate the student.	_____	_____
The student is receptive to engaging in some level of interaction at this time.	_____	_____
B. STUDENT COMMUNICATION		
The student has an effective and appropriate means of gaining attention in this activity.	_____	_____
The student is positioned so that he or she is aware that the teacher is present.	_____	_____
C. ADULT INTERACTION		
The teacher appears to enjoy the activity.	_____	_____
The teacher communicates to the student in a mode the student can understand.	_____	_____
D. GROUP DYNAMICS		
The group includes at least one peer who is a more competent communicator than the student.	_____	_____
The teacher switches easily from one communication system to another, if needed.	_____	_____
E. MATERIALS		
The materials are used for turn-taking. That is, the student and teacher take turns back and forth using the materials.	_____	_____
The student seems to enjoy this material.	_____	_____
F. OPPORTUNITIES FOR COMMUNICATION		
Teacher or peers offer choices of materials, tasks, or partners.	_____	_____
Teachers or peers ask yes/no questions for the student to confirm or negate.	_____	_____

Adapted from Rowland, C., & Schweigert, P. (1993). *Analyzing the communication environment (ACE): An inventory of ways to encourage communication in functional activities*. Tucson, AZ: Communication Skill Builders.

development in children with ASD who talk: one in which language development is appropriate or superior for age, and a second in which language is delayed in a way similar to that seen in other children with developmental language disorders. So simply knowing that a child with ASD uses multiword utterances doesn't tell us all we need to know about language strengths and weaknesses (just as it doesn't for any other child!). Preschoolers with ASD who function in the developing language phase should be assessed for all aspects of their language development—comprehension, production, phonology, syntax, semantics and pragmatics—just as we would assess any child with developing language.

Although using standardized tests to determine baseline level of language performance across the domains of communication makes sense for children with ASD, as it does for other children, it is important to bear in mind that standardized measures of assessment for this population may be especially misleading. Speakers with ASD can do well in the structured context of a test, but have greater difficulty using their language to engage in social interaction. For preschoolers with ASD who talk, pragmatics are likely to be the area of communication most affected by the disorder.

Parent-report measures of pragmatic and social skills are often a useful method of assessment for this population. The *Vineland Adaptive Behavior Scales—2* (Sparrow, Cicchetti, & Balla, 2005) is a parent interview that has been shown to reveal a distinct pattern among domain scores for children with ASD (Paul et al., 2004), and can be helpful in documenting social and communicative difficulties, especially for high-functioning children who do well on

standard language tests. The *Language Use Inventory* (O'Neill, 2007) can be used in a similar way.

These parent-report measures will allow us to document a gap between the strengths in language form and weaknesses in language use that are typically seen in ASD. But it will still be helpful to observe directly the conversational skills that each client shows. Again, language sample analysis may be the most valid assessment of these skills. For children with ASD, though, the focus will be less on syntax and morphology, and more on pragmatic aspects of interaction. Table 8-12 provides some suggestions for areas of pragmatic function that are often problematic for preschoolers with ASD, which can be observed in a conversational sample. It's important to remember, too, that children with ASD often look better with adults who frequently find their oddities appealing, than they do with peers who can be less forgiving. For this reason, observing a peer interaction within a preschool setting can be particularly enlightening. Table 8-13 provides a sample form for recording observations from conversational interactions at this level. This form can be used to identify areas in greatest need of remedial attention, and to document change as the intervention targets particular pragmatic behaviors.

CONCLUSIONS

Assessing the child with a language disorder at the developing language stage sounds like a big job. It is! Of course, not every single aspect of the assessment process is necessary for every child. Every

TABLE 8-12 Areas and Methods for Assessment of Conversational Pragmatics in Preschool Speakers with ASD

Area	Description	Assessment Method
Responsiveness	Children with ASD do not respond as consistently to hearing their name called, and may show minimal understanding of the conversational responsibility to respond when spoken to.	The number of times the child responds to his name can be examined as a proportion of the number of times the name was called. Likewise, the number of adult utterances to which the child responds with speech or meaningful gestures can be compared to the total number of adult utterances offered.
Echolalia	This includes immediate or delayed imitation of what is heard, or the repetition of strings of memorized language from songs, videos, or other "scripted" sources.	The proportion of echoed to spontaneous utterances can be analyzed. Echoed utterances can be further separated into immediate and delayed echolalia. The function of the echoed language should be recorded, in order to design intervention to replace the echoed language with more conventional means of communication to achieve the given functions.
Pronoun use	Children with ASD often use the pronoun "you" in place of "me" when referring to themselves. This is thought to reflect their tendency to echo what they hear others say. For example, when a caregiver asks a child, "Are you hungry?" the child with ASD may respond with the phrase, "You hungry."	Using a speech sample, the number of inappropriate uses of pronouns can be calculated as a proportion of total pronoun use.
Vocabulary and syntax	Children with ASD sometimes attach unusual or peculiar meanings to words or phrases; but syntax is generally a relative strength. Therefore, syntactic level, often determined by MLU, can be a baseline measure against which other areas of language skill may be measured.	Vocabulary diversity can be analyzed simply by recording the number of different words in the speech sample, or more formally by calculating the Type-Token ratio (i.e., number of different words divided by total number of words spoken). SALT can automatically compute both vocabulary and MLU measures from transcripts entered into their data systems. These values can be compared to those in the SALT's database. In addition, any idiosyncratic word use observed in children with ASD may be noted.
Communicative functions	Requesting (Can I have that?) Protesting (Don't do that!) Directing others (You go there.) Commenting (That's a blue car.) Social interaction (Hi, let's play.) Self-directing (I'm gonna hide the ball.) Reporting on past and ongoing events (We played on the swings.) Reasoning (The gerbil ran away 'cause we forgot to lock the cage.) Predicting (Mom'll get mad if I play in the mud.) Empathizing (She's crying 'cause she fell down.) Imagining (I'm the mommy; I'll put the baby to bed.) Negotiating (If you give me the truck, I'll give you the ball.)	Observe peer play interaction; note the number of <i>initiations</i> of communication as well as the number of different functions expressed.

assessment will, though, be family-centered. That means being responsive to the interests and concerns of the family; being sure that they are involved in all the decisions made about assessment and intervention for the child; and respecting their culture, traditions, and personal style. Let's go back to Jerry. Taking him as an exam-

ple, we can see how to use history and referral information to develop an assessment plan. As in any plan, we will be choosing tests and procedures to use in the evaluation process based on the areas we suspect may be problematic for the client and on the need to identify specific goals for the intervention program.

TABLE 8-13 Example Form for Assessing Pragmatics in Semi-Structured Conversation: Early Language Level

	Present	Absent	No opportunity
COMMUNICATIVE FUNCTIONS			
Directing others	_____	_____	_____
Self-directing	_____	_____	_____
Reporting	_____	_____	_____
Reasoning	_____	_____	_____
Predicting	_____	_____	_____
Empathizing	_____	_____	_____
Imagining	_____	_____	_____
Negotiating	_____	_____	_____
DISCOURSE MANAGEMENT			
Waits turn to speak	_____	_____	_____
Responds to speech w/speech consistently	_____	_____	_____
Responds to speech w/relevant remark	_____	_____	_____
Maintains other's topic for at least two turns	_____	_____	_____
Shifts topics appropriately	_____	_____	_____
Monitors interlocutor with gaze appropriately (looks at other when talking; looks at referents, then back at interlocutor)	_____	_____	_____
REGISTER VARIATION			
Talks appropriately to unfamiliar adult (clinician)	_____	_____	_____
Demonstrates at least one register shift (e.g., in talk to baby doll or stuffed animal)	_____	_____	_____
Uses politeness conventions in requests (please)	_____	_____	_____
Can increase politeness when told to "ask nicer"	_____	_____	_____
Uses indirect requests spontaneously and appropriately	_____	_____	_____
PRESUPPOSITION			
Uses pronouns appropriately	_____	_____	_____
Uses ellipsis appropriately	_____	_____	_____
Uses stress appropriately for emphasis and contrast	_____	_____	_____
Gives enough background information	_____	_____	_____
Can provide additional information when requested (A what?) for conversational repair	_____	_____	_____
MANNER OF COMMUNICATION			
Gives clear, relevant responses	_____	_____	_____
Talks appropriate amount	_____	_____	_____
Can relate sequence of actions clearly	_____	_____	_____

Adapted from Paul, R. & Wilson, K. (2008). Assessment of speech, language, and communication. In S. Goldstein, J. Naglieri, & S. Ozonoff (Eds.) *Assessment of autism spectrum disorders*. (pp. 171-208). N.Y.: Guilford Press.

Jerry's family brought him to the preschool assessment center of their local school district for an evaluation, as Mrs. Hamilton suggested. They met with the assessment team leader and the speech language pathologist, Ms. Warren. Ms. Warren asked the parents about Jerry's medical and feeding history; asked about how Jerry had vocalized as a baby; and wanted to know more about how, from the parents' point of view, he was communicating now. She asked them what their major concerns for Jerry were and how the assessment could help them understand his needs. The parents expressed some dismay with some of the things that Mrs. Hamilton had told them. They said they did not see Jerry's problems as serious. They were clear in their desire to

have Jerry take an IQ test to "prove" to Mrs. Hamilton that he was not "retarded." They weren't sure what they would do if the assessment identified a language disorder in Jerry. They felt confused and somewhat overwhelmed. They said they had never had a child with a problem before. They wanted to know what Ms. Warren thought. Was Jerry behind? Would he catch up? Did he need special help?

After this discussion, Ms. Warren explained that she would like to have Jerry's hearing tested before proceeding any further. She also said she would like to have a look at how Jerry was able to use his oral structures for speech and nonspeech functions. She explained that she doubted that Jerry was intellectually impaired and explained that if there were any question

of intellectual disability she would talk with them further and discuss a referral to a psychologist with them before taking any action. The parents agreed to this plan. When Jerry passed a hearing screening and did not appear to have any serious oral-motor problems, Ms. Warren asked whether the parents would be willing to bring Jerry back again for a more in-depth evaluation in a week or two. She explained that language learning is an extremely complex process and that many children run into obstacles along the way. She told them that even without intervention most children like Jerry eventually outgrew many of their difficulties. But she explained that, in her experience, many preschoolers were helped by the extra boost that focused intervention during the preschool period provided. She asked them not to make up their minds yet, but to consider the possibility of some short-term intervention to jump-start Jerry's language development, if the assessment indicated that it might be helpful. Jerry's parents agreed to reserve judgment until the assessment was completed.

After reviewing the referral information from Mrs. Hamilton and her notes from the preassessment interview, Ms. Warren devised the assessment plan.

Area to Be Assessed	Assessment Tool
Expressive vocabulary	<i>Expressive One-Word Picture Vocabulary Test—Revised</i> (Brownell, 2000)
Receptive vocabulary and syntax, expressive syntax, phonological skills	<i>Test of Language Development—Primary: 4</i> (Newcomer & Hammill, 2004)
FOLLOW-UP CRITERION-REFERENCED PROCEDURES TO BE USED, IF JERRY SCORES BELOW THE NORMAL RANGE IN RECEPTION, EXPRESSION, OR PHONOLOGY	
Expressive language	Language sample analysis, using IPSyn procedure. If needed, use elicited production tasks to look at structures that did not appear in spontaneous speech.
Phonology	Intelligibility in short conversational sample; phonetic inventory and phonological analysis, if needed, using same sample used for IPSyn.
Pragmatics	"Peanut butter protocol"

Ms. Warren conducted the formal portion of the assessment and shared the results with the parents. She explained that Jerry's receptive vocabulary and sentence structures were age-appropriate, so further testing in these areas was not needed. However, the tests suggested that his expressive syntax and his speech skills were below age level. She asked the parents whether they would be willing to return and allow her to audio-record one of them playing with Jerry so she could collect a sample of his speech and to allow her to play with him for a while to get a picture of the way he participated in communicative situations. She explained that the information she got from these assessments would be helpful in determining the specific

targets of an intervention program, if the parents decided Jerry could benefit from one.

The results of the criterion-referenced assessment revealed the following:

1. Jerry's speech-sample analysis, according to the IPSyn, showed that his score was significantly depressed. His noun phrase performance was adequate, but his use of verb phrases showed no structures above the level of simple copulas (V5). Questions and negatives also were limited in complexity. He produced no questions or negatives with auxiliaries (scored "0" on Q6, Q7, and Q8); no "why" questions; and no tag questions. On the sentence structure scale, he produced forms up to the conjoined phrase and simple infinitive level (S5 and S6), but none higher. Jerry's use of syntax showed deficits in the areas of verb phrase elaboration, use of negative and question forms, and use of advanced sentence structures.
2. The sounds that were absent from Jerry's inventory are all in the middle or late groups, according to Shriberg's (1993) scheme. This suggested that Jerry's speech sound development was delayed rather than deviant. Some of the sounds on which Jerry made errors, such as /k/, /g/, /s/, /f/, and /t/, do appear in the inventory, suggesting that he knows "how" to say these sounds. The phonological analysis showed that most of Jerry's error patterns were used inconsistently. This suggested that he can sometimes "tune up" his pronunciation to make it more accurate. Only /f/ and /v/ were dropped consistently at the ends of words, and only /θ/ was consistently stopped. Only initial clusters were consistently simplified; at least one final cluster appeared in correct form. Jerry did produce some multisyllabic words, with better accuracy in two syllables than in three. The patterns he used were all typical in development; no unusual patterns were noted. These findings suggested delayed speech sound development.
3. Jerry's performance on the "peanut butter protocol" showed that he performed adequately in terms of expressing communicative intentions and using conversational devices to engage in social interaction.

Ms. Warren suggested to the parents that Jerry could benefit from some intervention to improve his expressive language and articulation. She suggested that he be enrolled in the district's preschool language classroom, a language-focused preschool group taught by an SLP. However, the language classroom met at the same time as Jerry's mainstream preschool program, and the parents were reluctant to withdraw Jerry from that. Ms. Warren suggested that perhaps the parents would be willing to work with her on a consultative basis. She would talk to Mrs. Hamilton about some special activities to be done with Jerry within the mainstream preschool program and would give the parents activities to do with Jerry at home. She would make a home visit once a month to see how things were going, assess Jerry's progress, and suggest additional activities. She proposed that they try this plan for 6 months and see how things went. At that point everyone could re-evaluate the situation. The parents agreed to this plan and were very eager to do what they could to help Jerry at home. They agreed to meet again with Ms. Warren and Mrs. Hamilton to set up the ongoing consultative program.

STUDY GUIDE

- I. The Developing Language Stage
 - A. What is meant by “developing language” in terms of identification and assessment of language disorders?
 - B. What language characteristics are seen in children at this level of language development?
- II. Family-Centered Assessment
 - A. What does IDEA legislation require in terms of family participation?
 - B. How can parents be involved in the assessment of their child with developing language?
 - C. What are the family’s rights if conflicts arise between them and the assessment team about recommendations for services for their child?
- III. Assessing Collateral Areas
 - A. How would a speech-language pathologist working in a trans-disciplinary team assess areas collateral to language development? How would a clinician in private practice do so?
 - B. List collateral areas to consider when assessing a preschooler suspected of speech/language delay.
- IV. Screening for Language Disorders in the Period of Developing Language
 - A. Discuss the important properties to look for when choosing a screening instrument for children with developing language.
 - B. Why is it important to read the statistical information provided when choosing a screening instrument?
- V. Using Standardized Tests in Assessing Developing Language
 - A. What is the purpose of using standardized tests in assessment of developing language?
 - B. Why do standardized tests often not provide enough information for intervention planning?
- VI. Criterion-Referenced Assessment and Behavioral Observation for Children with Developing Language
 - A. How is criterion-referenced assessment used to supplement standardized testing?
 - B. What is the role of intelligibility assessment in speech sound evaluation?
 - C. Discuss methods of criterion-referenced speech sound assessment.
 - D. What are some of the difficulties and dangers of assessing the unintelligible child?
 - E. How does the concept of “fast mapping” affect the assessment of vocabulary skills?
 - F. How can word retrieval skills be assessed in a child with developing language?
 - G. Describe a general strategy for assessing vocabulary skills in children with developing language.
- H. Why must receptive and expressive syntax be assessed separately?
- I. Discuss the assessment of contextualized and decontextualized comprehension skills.
- J. Describe two methods for nonstandardized assessment of decontextualized comprehension; of contextualized comprehension.
- K. Why and how do we assess comprehension strategies?
- L. What is the role of speech-sample analysis in assessing productive syntax and morphology?
- M. What situations, partners, and materials are best for collecting a speech sample from a child with developing language?
- N. How is MLU computed, and for what purposes is it used? What are its advantages and disadvantages?
- O. Discuss how the efficiency of speech sampling can be increased.
- P. Compare and contrast the Assigning Structural Stage Procedure, IPSyn, and DSS procedures.
- Q. What is the purpose of using elicited production procedures in criterion-referenced assessment? Give two examples of elicited production activities.
- R. What is the goal of pragmatic assessment for a child with developing language? Discuss four methods of pragmatic assessment.
- S. How can the results of a pragmatic assessment be used in intervention planning?
- T. What is the difference between phonological processing and phonological processes?
- U. Describe two methods of informal assessment of phonological processing for preschool children.
- VII. Considerations for Assessing Older Clients with Severe Impairment and Speakers with ASD at the Developing Language Level
 - A. What is meant by providing *access* and *opportunity* for older students with severe language disorders?
 - B. Discuss the use of an ecological inventory to assess the communicative needs of an older, severely impaired client.
 - C. What areas of interaction can be examined in an ecological inventory?
 - D. Describe the way in which an SLP develops a communication profile for a severely affected client, and how the profile can be used in supporting the students’ communication in everyday settings.
 - E. List two parent report measures that can be used to assess pragmatic skills in preschoolers with ASD.
 - F. What is the role of language sampling for preschool speakers with ASD?

APPENDIX

8-1

A Sample of Articulation Screening Tools for the Developing Language Level

Test (Name, Author[s], Date, Publisher)	Developmental Range	Comments
<i>Arizona Articulation Proficiency Scale—Third Edition</i> (Fudala, 2001)	1:6–18 yr	Identifies misarticulations and total articulatory proficiency Provides intelligibility descriptions Administration time: 10 min
<i>Hodson Assessment of Phonological Patterns—Preschool Phonological Screening</i> (HAPP-3; Hodson, 2004)	Preschool	See HAPP-3 in Table 8-3 Yields pass/fail score Uses objects rather than pictures Administration time: 2–5 min
<i>Denver Articulation Screening Exam</i> (DASE; Drumwright, 1973)	2:6–7 yr	Administration time: 5 min
<i>Fluharty Preschool Speech and Language Screening Test—Second Edition</i> (Fluharty, 2000)	3–6:11 yr	Standardized on multiracial, multiethnic group of 705 standard English-speaking children Uses common objects for naming Administration time: 10 min
<i>Kaufman Speech Praxis Test for Children</i> (KSPT; Kaufman, 1995)	2–5:11 yr	Identifies the level of breakdown in a child's ability to speak Assists in assessment of dyspraxia of speech in preschool children Administration time: 5–15 min
<i>Photo Articulation Test—Third Edition</i> (PAT-3; Lippke, Dickey, Selmar, & Soder, 1997)	3–8:11	See Table 8-3 Can be adapted for screening Administration time: 20 min
<i>Preschool Language Scale (Fourth Edition) Screening Test Kit</i> (PLS-4 Screening Test; Zimmerman, Steiner, & Pond, 2011)	3–6:11 yr	Screens a variety of skills including articulation and language Administration time: 5–10 min
<i>Screening Test for Developmental Apraxia of Speech—Second Edition</i> (Blakely, 2000)	4–12 yr	A screening instrument to assist in the differential diagnosis of developmental apraxia of speech Areas assessed include expressive language discrepancy, vowels and diphthongs, oral-motor skills, verbal sequencing, and articulation
<i>Slosson Articulation, Language Test with Phonology</i> (SALT-P; Wade & Slosson, 1986)	3–5:11 yr	Incorporates screening of articulation, phonology, and language into a single score that shows a child's communicative competence Administration time: 7–10 min
<i>Templin-Darley Tests of Articulation</i> (Templin & Darley, 1969)	3–8 yr	See Table 8-3 Has a 50-item screening test

A Sample of Language Screening Tools at the Developing Language Level

Test (Name, Author[s], Date, Publisher)	Developmental Range	Areas Assessed	Comments
<i>Bankson Language Screening Test—Second Edition</i> (Bankson, 1990)	4–7 yr	Receptive and expressive: semantics, morphology, syntax, auditory and visual perception	Lists 38 of the most discriminating items as appropriate for quick screen, but gives no norms for this screen Standardized on 637 children, all socioeconomic levels Test-retest reliability = 0.94 Concurrent validity: with PPVT = 0.54 with Boehm = 0.62 with TACL = 0.64 Administration time: 30 min See Table 8-4
<i>Battelle Development Inventory Screening Test—Second Edition</i> (BDI-2; Newborg, 2004)	Birth–8 yr	Communication, cognitive, personal-social, adaptive-motor	Standardized on 800 children nationwide Administration time: 10–30 min
<i>Denver II</i> (Frankenburg et al., 1990)	2 wk–6 yr	Language, expressive-receptive vocabulary, concepts, personal-social, fine and gross motor	Gives age range for percentage of children who pass each item Standardized on 1032 children in Denver who varied socioeconomically and racially Interrater reliability = 0.62–0.79 Administration time: 15–20 min
<i>Early Screening Profiles</i> (ESP; Harrison et al., 1990)	2–6:11 yr	Profiles cognitive, language, self-help and social, motor; surveys articulation, home health behavior	ESP claims link with K-ABC, Vineland, and Bruininks-Osteretsky Test of Motor Proficiency Nationally standardized on more than 1100 children Yields standard, age-equivalent, and percentile scores Administration time: 15–30 min
<i>Fluharty Preschool Speech and Language Screening Test—Second Edition</i> (Fluharty, 2000)	3–6:11 yr	Articulation, receptive and expressive language, composite language	Allows assessment of Black English Dialect Provides standard scores and age equivalents Standardized on 705 children from varied racial, ethnic, and socioeconomic status (SES) and from 21 states Administration time: 5–10 min
<i>Joliet 3-Minute Speech and Language Screen—Revised</i> (Kinzler & Johnson, 1993)	K, 2nd, and 5th grades	Expressive syntax, receptive vocabulary, articulation, voice and fluency	Has computer program for record-keeping Provides pass/fail, cutoff score for each grade Standardized on 2587 children from three different SES and ethnic backgrounds Administration time: 3 min
<i>Kindergarten Language Screening Test—Second Edition</i> (KLST-2; Gauthier & Madison, 1998)	3:6–6:11 yr	School readiness	Identifies children who need further diagnostic testing to determine whether they have deficits that will impede academic achievement Administration time: 5 min

A Sample of Articulation Assessment Tools at the Developing Language Level

Test (Name, Author[s], Date, Publisher)	Developmental Range	Comments
<i>Arizona Articulation Proficiency Scale—Third Edition</i> (Fudala, 2001)	1:6–18 yr	Standardized on 5500 children from nationwide sample Reliability (interrater) = 0.68–0.99 (test-retest) = 0.96 Internal consistency = 0.77–0.94 Concurrent validity = 0.82–0.89 (with Photo Articulation Test, Goldman-Fristoe Test of Articulation, Templin-Darley Tests of Articulation) Administration time: 2–10 min Scores: percentile, T-score, standard score Administration time: 5–10 min
<i>Articulation Testing for Use with Children with Cerebral Palsy</i> (Irwin, 1961)	3–16 yr	Scores: percentile, T-score, standard score Administration time: 5–10 min
<i>Assessment Link Between Phonology and Articulation—Revised</i> (ALPHA-R; Lowe, 2009)	3–8:11 yr	Assesses phonetic repertoire through sound-in-position analysis, and assesses deviant use of phonological processes Scores: standard, percentile Administration time: 15 min
<i>Hodson Assessment of Phonological Patterns—Third Edition</i> (HAPP-3; Hodson, 2004)	Preschool	Normative data for 3–8 yr Uses objects and some pictures Administration time: 15–20 min
<i>Bankson-Bernthal Test of Phonology</i> (BBTOP; Bankson, 1990)	3–9 yr	Tests 23 consonants, clusters Scores by phonological process or phoneme Provides consonant inventory, phonological process inventory Yields percentile ranks and standard scores Normed on a sample of 1000 children similar to national average in ethnic composition High reliability (0.95 internal consistency, 0.89 test-retest) Administration time: 15 min
<i>Bzoch Error Pattern Diagnostic Articulation Test</i> (BEPDAT; Bzoch, 1971)	3–6 yr	Useful for clients with structural abnormalities of the oral mechanism
<i>Central Institute for the Deaf Phonetic Inventory</i> (Moog, 1988)	3–15 yr	Evaluates phonetic aspects of speech, primarily in the context of syllables, typically elicited through imitation of spoken model Phonetic Skills Profile summarizes scores Useful for establishing objectives and documenting progress Administration time: 30 min
<i>Compton Phonological Assessment</i> (Compton & Hutton, 1978)	3 yr–adult	Uses sentence completion Administration time: 90 min
<i>Deep Test of Articulation</i> (McDonald, 1968)	3–12 yr	Tests articulation of sounds in various phonetic contexts to determine contexts that will facilitate correct production
<i>Fisher-Logemann Test of Articulation Competence</i> (FLTOAC; Fisher & Logemann, 1971)	3 yr–adult	Has screening form available Sentence portion for 3rd grade and above Provides distinctive feature analysis Administration time: 45 min
<i>Goldman-Fristoe Test of Articulation—Second Edition</i> (GFTA-2; Goldman & Fristoe, 1999)	2–21 yr	Can be used with Khan-Lewis Phonological Analysis Yields percentile rank by age score Administration time: 10–15 min for single-word portion

Test (Name, Author[s], Date, Publisher)	Developmental Range	Comments
<i>Iowa Pressure Articulation Test</i> (IPAT; Morris, Spriestersbach, & Darley, 1961)	3–8 yr	Consists of 43 items from Templin-Darley Tests of Articulation; assesses velopharyngeal closure
<i>Kaufman Speech Praxis Test for Children</i> (KSPT; Kaufman, 1995)	2–5:11 yr	Assists in the developmental diagnosis and treatment of apraxia of speech in preschool children Identifies the level of breakdown in a child's speech Administration time: 5–15 min
<i>Khan-Lewis Phonological Analysis - Second Edition</i> (KLPA-2; Khan & Lewis, 2002)	2–21 yr	Use with Goldman-Fristoe Test of Articulation Yields percentile ranks, age equivalent; percentage occurrence of processes Standardized on 1175 males + 1175 females at 11 age groups; groups contain mix of genders, races, ethnic and geographical distributions Test-retest reliability; 0.94 across all phonological processes Administration time: 10–30 min
<i>Natural Process Analysis</i> (NPA; Shriberg & Kwiatkowski, 1980)	All ages	Requires 90 words from spontaneous speech sample Yields phonetic inventory; data on use of eight phonological processes Administration time: 15 min
<i>Phonological Process Analysis</i> (PPA; Weiner, 1979)	2–5 yr	Uses spontaneous and elicited production Looks at words in sentence context
<i>Photo Articulation Test—Third Edition</i> (PAT-3; Lippke, Dickey, Selmar, & Soder, 1997)	3–12 yr	Can be adapted for screening Provides means and standard deviations for age Normed on 684 children 3–12 yr Concurrent validity = 0.82 with Templin Darley Tests of Articulation Administration time: 25–30 min
<i>Structured Photographic Articulation Test II Featuring Dudsberry</i> (SPAT-DII; Dawson & Tattersall, 2001)	3–9 yr	Uses 48 photographs to assess 59 consonant singletons and 21 consonant blends Identifies phonological processes used by preschool and school-age children Administration time: 10–15 min
<i>Templin-Darley Tests of Articulation</i> (Templin & Darley, 1969)	3–8 yr	Has 50-item screening test plus Iowa Pressure Articulation Test for assessment of velopharyngeal closure Uses words, sentences, and sentence completion Provides means and standard deviations for age Test-retest reliability = 0.93–0.99
<i>Test of Articulation in Context</i> (TAC; Lamphere & Menard, 1998)	Preschool–elementary	Based on the premise that articulation skills are most accurately represented in spontaneous speech; uses pictures to elicit all common consonants, consonant clusters, and vowels Administration time: 20–30 min
<i>Test of Minimal Articulation Competence</i> (TMAC; Secord, 1981)	3 yr–adult	Has 24-item quick screen Yields developmental articulation index Test-retest reliability = 0.94 Administration time: 10–20 min
<i>The Apraxia Profile</i> (Hickman, 1997)	2–12 yr	Helps identify the presence of oral apraxia, diagnose developmental verbal apraxia, and determine oral motor movement and sequence disorders Administration time: 25–35 min
<i>Weiss Comprehensive Articulation Test</i> (WCAT; Weiss, 1980)	Preschool–adult	Based on studies by Prather, Hendrick, & Kera (1975); Pendergast et al. (1966); and Templin (1957) Yields age-equivalent, intelligibility, stimulability score Standardized on 4000 children (ages 3–8) Test-retest reliability = 0.96 Administration time: 20 min

A Sample of Language Assessment Tools at the Developing Language Level

Test (Name, Author[s], Date, Publisher)	Developmental Range	Areas Assessed	Comments
<i>Assessment, Evaluation, and Programming System for Infants and Children—Second Edition</i> (AEPS; Bricker, 2002)	Birth–6 yr	Assesses the skills and abilities of children who are at risk or who are functioning at a developmental age of birth–6 yr	Curriculum-based assessment/evaluation system that provides a framework for developing goals and objectives in intervention Measures functional skills and abilities, gathers data by observing in familiar environments, refers to IFSP/IEP goals
<i>Batelle Developmental Inventory—Second Edition</i> (Newborg, Stock, & Wnek, 2004)	Birth–8 yr	Speech and language, social/emotional, cognitive, motoric skills, learning, and hearing	Normative data gathered from over 2500 children Includes optional scoring software so data can be input to a Web-based program or on a smart phone. Scoring includes standard scores, age equivalents, and cut-off scores Administration time: 1–2 hr Yields age equivalent, percentile, T-scores Standardized on 433 children in 17 states; stratified by sex, race, region, SES Test-retest reliability = 0.87–0.94 Internal consistency = 0.88 Administration time: 20–30 min
<i>Boehm 3—Preschool</i> (Boehm, 2001)	3–5:11 yr	Receptive concepts: space, time, quantity	Downward extension of <i>Clinical Evaluation of Language Fundamentals—Revised</i> Yields standard, percentile scores, receptive and expressive composites Standardized on 1,500 children Administration time: less than 1 hr Normed on 1000 nationwide
<i>Clinical Evaluation of Language Fundamentals—Preschool—Second Edition</i> (CELF; Wiig, Secord, & Semel, 2004)	3–6 yr	Concepts, syntax, semantics, morphology	
<i>Communication Abilities Diagnostic Test</i> (CADET; Johnston & Johnston, 1990)	3–9 yr	Syntax, semantics, pragmatics	
<i>Coordinating Assessment and Programming for Preschoolers</i> (CAPP; Karnes, & Johnson, 1991)	3–5 yr	6 domains: language, social, general knowledge, school readiness, fine and gross motor	Includes classroom and home activities program
<i>Detroit Test of Learning Aptitude-Primary—Third Edition</i> (DTLA-P:3; Hammill & Bryant, 2005)	3–9:11 yr	Domains: linguistic, cognitive, attentional, motoric	Has software available for scoring Has articulation measure Includes items measuring conceptual matching, design reproduction, digit sequences, following directions, word opposites, motor directions, visual discrimination, and other skills Yields standard score, percentile, developmental quotient (DQ), age equivalent Normed on 1976 children Construct validity and reliability data available Administration time: 15–45 min

Test (Name, Author[s], Date, Publisher)	Developmental Range	Areas Assessed	Comments
<i>Developmental Sentence Score (DSS; Lee, 1974)</i>	2–7 yr	Expressive language: indefinite pronouns, personal pronouns, main verbs, secondary verbs, negatives, conjunctions, interrogative reversals, <i>wh-</i> questions	Speech-sample analysis Use for Standard American dialect only Yields developmental sentence score and scores for 10th, 25th, 75th, 90th percentiles for each age Standardized on 200 children in Illinois; mostly middle-class; 10 each at 3-mo intervals, ages 2 yr–6:11 yr
<i>Evaluating Acquired Skills in Communication—Third Edition (EASIC-3; Riley, 2008)</i>	3 mon–6:3 yr	Semantics, syntax, morphology, pragmatics	For evaluation of severely language impaired Administration time: 15–30 min
<i>Expressive One-Word Picture Vocabulary Test—2000 Edition (EOWPVT [2000]; Brownell, 2000)</i>	2–18 yr	Expressive vocabulary	Spanish version available Norming sample related to ROWPVT Yields standard, percentile, age-equivalent scores Administration time: 10–15 min
<i>Expressive Vocabulary Test—Second Edition (EVT-2; Williams, 2007)</i>	2:6–adult	Naming, synonyms	Normed on same children as PPVT Designed as a companion expressive assessment to PPVT Administration time: 10–20 min
<i>Grammatical Analysis of Elicited Language (Moog & Geers, 1985)</i>	2:6–5 yr	Syntax: articles, adjectives, possessives, demonstratives, conjunctions, <i>wh-</i> questions, copula, prepositions, negatives	Video available for training administrator Yields profile, not standard scores Standardized on 200 hearing-impaired and 200 normal-hearing children
<i>Illinois Test of Psycholinguistic Abilities—Third Edition (ITPA-3; Hammill, Mather, & Roberts, 2001)</i>	5–13 yr	The Global Composites scores are: General Language, Spoken Language and Written Language Specific Composites scores include: Semantics, Grammar, Phonology, Comprehension, Spelling, Sight-Symbol Processing, and Sound-Symbol Processing	Standard scores, percentiles, age and grade equivalents The ITPA-3 Scoring Software and Report System, sold separately, automatically converts raw scores into standard scores, percentile ranks, and age equivalents. Administration time: 45–60 min
<i>Miller-Yoder Language Comprehension Test (MY; Miller & Yoder, 1984)</i>	4–8 yr	Receptive grammar and morphology	Normed on 120 preschool and kindergarten children Scores yield developmental profile Yields percentage correct with pass/fail criteria Administration time: 15–30 min
<i>Peabody Picture Vocabulary Test—Fourth Edition (PPVT-4; Dunn & Dunn, 2006)</i>	2:6 yr–adult	Receptive vocabulary	Spanish version available Yields standard score, percentile, age equivalent, stanine, standard error of measurement Standardized on 4012 children ages 2–18 years Administration time: 10–20 min
<i>Porch Index of Communicative Ability in Children (PICA; Porch, 1981)</i>	3–12 yr	Verbal, gestural, graphic abilities	Scores responses qualitatively Yields percentile score, gives means for age Standardized on several hundred children representative of U.S. population Administration time: 30–60 min
<i>Preschool Language Assessment Instrument—Second Edition (PLAI-2; Blank, Rose, & Berlin, 2003)</i>	3–6 yr	Matching perception, analysis of perception, reasoning about perception	Assesses ability to use and understand the “language of learning” at varying levels of abstraction Available in Spanish Provides numerical and qualitative scores Gives reliability and validity data Administration time: 30 min

Continued

Test (Name, Author[s], Date, Publisher)	Developmental Range	Areas Assessed	Comments
<i>Preschool Language Scale—Fifth Edition</i> (PLS-5; Zimmerman, Steiner, & Pond, 2011)	Birth–7:11 yr	Language precursors; expressive and receptive semantics, syntax, morphology, integrative thinking, auditory comprehension	Includes family information form Spanish version available Articulation screening included (see Table 8-1) Can be used as criterion-referenced test for older child Yields standard scores, percentile, age equivalent Standardized on 1500 children nationwide Administration time: 20–45 min
<i>Receptive One-Word Picture Vocabulary Test—2000 Edition</i> (Brownell, 2000)	2:11–12 yr	Receptive vocabulary	Spanish version available Yields standard, percentile, age-equivalent score Similar to norming population for Expressive One-Word Picture Vocabulary Test Administration time: 20 min Criterion-referenced measure
<i>Rice-Wexler Test of Early Grammatical Impairment</i> (TEGI; Rice & Wexler, 2001)	3.0–8.0	Grammatical morphology	
<i>Sequenced Inventory of Communication Development—Revised</i> (SICD-R; Hedrick, Prather, & Tobin, 1984)	4 mon–4 yr	Receptive language (speech and sound awareness and understanding); expressive language (imitating, initiating, responding)	Incorporates speech sample Age norms for receptive and expressive scales Has adapted version for older clients with physical disabilities Standardized on 252 white children from varied socioeconomic backgrounds Administration time: 30–45 min, longer to score
<i>Structured Photographic Expressive Language Test—Preschool-2</i> (SPELT-P2; Dawson et al., 2004)	3–5:11 yr	Syntax and morphology	Spanish version available Yields standard scores, confidence intervals, percentile ranks, percentile bands, and test-age equivalents Administration time: 10–15 min
<i>Structured Photographic Expressive Language Test-3</i> (SPELT-3; Dawson & Stout, 2003)	4–9:11 yr	Syntax and morphology	Has guidelines for scoring Black English dialect. Standardized on more than 1800 children nationwide. Administration time: 15–20 min Spanish version available (second edition). Yields standard, percentile, age-equivalent scores.
<i>Test for Auditory Comprehension of Language—Third Edition</i> (TACL-3; Carrow-Woolfolk, 1999a)	3–9:11 yr	Receptive language: word classes and relations, grammatical morphemes, elaborated sentence constructions	Spanish version available Yields percentile standard score, age equivalent Normed on 1003 children Administration time: 15–25 min
<i>Test of Early Language Development—Third Edition</i> (TELD-3; Hresko, Redi, & Hammill, 1999)	2:7–11 yr	Receptive and expressive syntax, semantics	Yields standard scores, percentile, age equivalent Normed on 1184 children in 30 states Administration time: 15–20 min
<i>Test for Examining Expressive Morphology</i> (TEEM; Shipley, Stone, & Sue, 1983)	3–7:11 yr	Present progressive plurals, possessives, past tenses, third-person singular, derived adjectives	Uses sentence completion Has companion program—Teaching Expressive English Morphology Yields age equivalent, means, and standard deviation for 6-month intervals Normed on 540 children Construct validity = 0.87 Intrarater and interrater reliability = 0.94 Administration time: 7 min
<i>Test of Language Development—Fourth Edition: Primary</i> (TOLD-4:P; Newcomer & Hammill, 2008)	4–8:11 yr	Receptive and expressive semantics and syntax	Has graph for visual representation of scores Uses imitation, sentence completion, picture pointing Yields standard scores, percentile, and equivalent quotients Nationally standardized on more than 2000 children in 28 states and Canada Administration time: 30–60 min

Test (Name, Author[s], Date, Publisher)	Developmental Range	Areas Assessed	Comments
<i>Test of Relational Concepts</i> (Edmonston & Thane, 1993)	3–8 yr	Receptive semantics	Normed on 1000 children
<i>Test of Pragmatic Skills—Revised</i> (Shulman, 1986)	3–8 yr	Pragmatics: verbal, and nonverbal, naming and labeling, reasoning, denying	Uses structured elicitation format
<i>Test of Pragmatic Language—Second Edition</i> (TOPL-2; Phelps-Terasaki & Phelps-Gunn, 2007)	6–18 yr	Comprehensive assessment of student's abilities to use pragmatic language effectively	TOPL test items provide information within six core subcomponents of pragmatic language: physical setting, audience, topic, purpose (speech acts), visual-gestural cues, and abstraction Administration time: 45–60 min Yields standard, percentile, age-equivalent scores
<i>Test of Semantic Skills—Primary</i> (TOSS-P; Bowers, Huisinigh, LoGiudice, & Orman, 2002)	4–8 yr	Receptive and expressive semantics: labels, categories, attributes, functions, definitions; has 6 themes: learning and playing, shopping, household, working, meals and health, and fitness	Standardized on 1500 students nationwide Previously called <i>Assessing Semantic Skills Through Everyday Themes</i> (ASSET) Administration time: 25–30 min
<i>Token Test for Children—Second Edition</i> (TFFC-2; McGhee, Ehrler, & DiSimoni, 2007)	3–12 yr	Auditory comprehension, temporal and spatial concepts	Yields age- and grade-equivalent score. Standardized on 1300 children (urban and rural) Administration time: 10–15 min
<i>Utah Test of Language Development—Fourth Edition</i> (Mecham, 2003)	3–9:11 yr	Receptive and expressive language, auditory comprehension	Yields standard scores and language quotient. Administration time: 30–45 min
<i>Wiig Criterion-Referenced Inventory of Language</i> (Wiig, 1990a)	4–13 yr	Semantics, pragmatics, syntax, morphology	No norm-referenced scores; use as criterion-referenced procedure
<i>Woodcock Language Proficiency Battery—Revised</i> (Woodcock, 1991)	2–95 yr	Oral language, vocabulary, antonyms and synonyms, reading and writing	Compuscore software for scoring Spanish form available Yields standard, age- and grade-equivalent scores Nationally standardized on 6300 students Reliability coefficients = 0.95 Administration time: 20–60 min

Intervention for Developing Language

CHAPTER OBJECTIVES

Readers of this chapter will be able to do the following:

1. Discuss intervention policy issues at the developing language level.
2. Describe intervention goals appropriate for developing language.
3. List a range of intervention procedures with an evidence base in the developing language period.
4. Discuss the SLP's role in developing emergent literacy skills.
5. Describe various contexts and models of service provision at the developing language level.
6. Discuss intervention issues and strategies for older clients with severe impairment who function at the developing language level.
7. Describe interventions aimed at improving communication and social integration for children with autism spectrum disorder (ASD) at the developing language level.

Rachel was a friendly, likable little girl who loved to talk even though people sometimes had trouble understanding what she said. She was born with Down syndrome and has been enrolled in early intervention since she was an infant, first in a home program and later in a mainstream preschool, with special services in speech-language and special education provided by the local school district. Now she was close to 7 years old. Her parents were very committed to continuing mainstream education for Rachel, and her preschool teacher, special educator, and speech-language pathologist (SLP) thought Rachel could function in a mainstream kindergarten class, with some support services. Her school district and the kindergarten teacher were somewhat hesitant to go along with this plan. The kindergarten teacher was afraid Rachel would “hold her class back.” The school district felt it would be more manageable logistically to provide services in a self-contained program for children with intellectual disabilities (ID), which was housed on the other side of town from Rachel's home. The school district developed an Individualized Educational Plan (IEP) for Rachel that included the self-contained class placement. At the IEP meeting, the parents rejected that plan, insisting that Rachel be allowed to try the kindergarten class in the neighborhood school. Reluctantly, the school-district team agreed to the plan and devised a range of special services that Rachel would receive within the classroom setting, including special education, speech-language pathology, and occupational therapy.

Ms. Snyder was to deliver the SLP services for Rachel. The IEP team had done a thorough assessment in several areas, including speech and language. The assessment report stated that Rachel's cognitive skills were close to a 5-year level, and her receptive language scores were between 42 and 54 months in most areas assessed. Her expressive skills, including vocabulary, phonology, expressive syntax, and morphology, were uniformly lower, though. She used a variety of substitution processes and was moderately unintelligible. Her sentences were primarily two or three words long with absent verb marking and grammatical morphemes and frequent errors in pronoun use. She was a good communicator, though, eager to initiate conversation, responsive to others' speech, and able to express a variety of communicative functions with the language she had at her disposal. Ms. Snyder met with the kindergarten teacher to begin to develop a program that would address Rachel's needs for language intervention and help her to succeed in the classroom.

Rachel is a child who, although older than preschool age, functions in the developing language (DL) period, the time at which words are combined in sentences but fully grammatical forms and a full range of meanings have not yet been acquired. Like children who are chronologically of preschool age, children Rachel's age or even older who have not yet mastered all the basic structures and functions of language typically acquired during the preschool years can be candidates for interventions that follow some of the principles and methods discussed in this chapter. Before looking in detail at the goals, procedures, and contexts of intervention for children with DL, though, let's look at some of the legislation and social policy issues we need to be aware of when designing intervention programs for children at this level.

INTERVENTION POLICY ISSUES AT THE DEVELOPING LANGUAGE LEVEL

Individualized Educational Plans

We talked in Chapters 6 and 7 about the reauthorized Individuals with Disabilities Education Act (IDEA) of 2004, the federal law that mandates free, appropriate public education (FAPE) to all children with handicaps. Part B of IDEA is concerned with school-age children, but its mandate extends to 3- to 5-year-olds as well. We talked about using the Individual Family Service Plan (IFSP) mandated under IDEA to plan intervention services for infants, toddlers, and their families. Educational plans for preschoolers and for older children with disabilities who function at DL levels, however, may be written in a somewhat different format. This format is the Individual Educational Program (IEP). IEPs differ from

IFSPs in several ways. The content and format are somewhat dissimilar. The biggest difference is that the focus of the IEP is on the child, rather than on the family. IEPs do not by any means leave the family out of the picture, though. IDEA has some very specific requirements about how families participate in the process of developing an IEP. The family is considered central members of the IEP team. They must be notified of an IEP meeting with sufficient time for them to arrange to attend. The meeting must be at a time that is convenient for both educational staff and parents. The parents have the right to accept or reject the IEP and to request that modifications be made to it. They also must approve the plan being proposed for the child before any program is initiated. A sample IEP format is provided in [Appendix 12-1](#).

Intervention Settings

The other big difference between intervention for toddlers and for preschoolers is where the intervention takes place. In most states birth-to-3 services are provided in the child's home or care setting, by interventionists who travel from child to child to provide individual intervention and care-giver training. When children turn 3, however, responsibility for their education moves from the birth-to-3 system to the local educational authority (LEA), where it stays until they graduate from high school or turn 21. This generally means that many children with disabilities "start school" at age three, when the location of their intervention moves from their home or local care setting to a school classroom, where a group of children receive instruction. For many children and families, this is a big change that can cause anxiety and stress. Most birth-to-3 services work with local school personnel to provide some form of transitional planning to make this move smoother.

Family-Centered Practice

The best practice for all our clients is family-centered; this is especially true for young children. Does this mean that family members must deliver the intervention? Not necessarily. As we discussed in Chapter 7 when we talked about intervention for emerging language, we need to remember that every family is different. For some families, having parents be primary agents of intervention makes sense. In these families, parents may feel they want to be centrally involved in their child's program, that they have the time and energy to devote to delivering the intervention, and that they are comfortable with the shift in role from parent to teacher.

Other families may not feel able or eager to take on that role but will want to have some supplementary part to play. They may want to do small amounts of "homework" to follow up on what is being done in the intervention setting. They may want to observe the intervention without participating directly. Other families may feel more comfortable having the large majority of the intervention done by "the pros." They may just want periodic updates on the child's progress. Family-centered intervention means respecting the family's wishes on the extent to which they want to be involved. Although we always want to encourage families to be as involved as possible and set up the intervention situation so that they can achieve this level of involvement, we never want to make families feel inadequate about the level of contribution they can make.

A second issue in family-centered intervention involves the extent to which families are involved in the choice of intervention goals and methods. As we discussed in Chapter 3, for most clients

there are more potential goals than there is intervention time to achieve them. This means we must pick and choose among the potential targets. In Chapter 3, we talked about some criteria to use in making this selection, such as teachability, functionality, and so on. Another factor to be considered, though, is family preference. Families are very likely to have feelings and opinions about areas in which they would like their child to show improvement. This information is an important part of the intervention planning process. We have an obligation, in family-centered practice, both to elicit this information from parents and to take it seriously in devising the intervention program.

Take Rachel as our example again. Suppose her parents felt that an important communicative goal was to get her to use "good sentences" such as "I'm hungry" and "He's a friend" instead of "Me hungry" and "Him friend," as she currently does. They feel these kinds of usages make Rachel sound babyish and will cause her problems among her peers in the kindergarten class. Perhaps the language clinician feels that such sentences containing copula verbs that agree in person and number with nominative pronouns are not the most appropriate goal, since Rachel is still lacking developmentally earlier forms. Who's right? In family-centered intervention, being right is not necessarily the issue. Perhaps the more important question is, how can this disagreement be resolved so that Rachel's development is the foremost consideration? The clinician can communicate, in a clear, respectful, and nonthreatening way, her opinion that Rachel is not yet ready to meet the standard of these "good sentences" and needs to learn other areas of language to serve as a basis for these later acquisitions. But suppose Rachel's family continues to assert a strong desire to have Rachel work toward this goal? Family-centered practice dictates that we concede the parents' right to determine what is important for their child to learn. Even if we do not entirely agree with the family's choice of communicative goals for their child, we have an obligation to honor the family's wishes if at all possible and to use family priorities in selecting and sequencing intervention goals.

Family-centered practice for the child with DL, just as for the child at other stages of language acquisition, means actively involving the family in all levels of decision-making about the child's program. It means having meaningful discussions about the assessment findings and sincerely soliciting the parents' input as we design the intervention program. It means deciding with the family how much direct involvement with the intervention program they feel able to manage and how much professional input they want. Finally, it means remembering that even our best clinical judgment must occasionally take a back seat to the parents' desires for their children.

INTERVENTION FOR DEVELOPING LANGUAGE: PRODUCTS, PROCESSES, AND CONTEXTS

In Chapter 3, we talked about three aspects of intervention that McLean (1989) suggested we consider when designing a management plan for a child with a language disorder: the *products*, or intended goals of the intervention; the *processes*, or methods used to achieve these goals; and the *context*, or physical and social milieu in which the intervention takes place. Let's look at each of these aspects of the intervention program and see how they apply to children in the DL phase.

Intervention Products: Goals for Children with Developing Language

For many children who, like Rachel, are within or only a few years beyond the preschool period chronologically, goals of intervention include some of the forms and functions acquired by typical children between 3 and 5 years of age. Some special considerations are involved in planning intervention programs for older, severely impaired clients still in the DL phase, which we will discuss later. In general, though, the goals for language intervention in this phase are to help the child acquire intelligible, grammatical, flexible forms of expression for the ideas and concepts the child has in mind, to enable the child to understand others, to give the child the tools to make communication effective, efficient, and rewarding so that social interaction proceeds as normally as possible, and to strengthen the oral language basis for success in literacy. As we discussed in the previous chapter, the preschool years are normally a period of exponential language growth, when children with typical development move from mean lengths of utterance of less than two words to more than five. Another way to describe this period is to say it is the interval between Brown's (1973) stages II and V+, the period of the acquisition of basic structures, functions, and meanings of the language. Table 9-1 reviews some of the major changes that take place in the language of normally developing children during the preschool years. These milestones provide a basis for establishing the goals of intervention at the DL level.

One thing you will probably notice right away about the list in Table 9-1: it's long. Not every child with DL will achieve everything on this list during the intervention period. As always, we will have to choose intervention goals judiciously. Knowing the normal sequence of acquisition is necessary to make these decisions, but it is not enough. Other considerations, such as those discussed in Chapter 3 and those we just talked about in terms of family involvement, must come into play. Later we'll talk more about the issue of choosing intervention goals for the older, severely impaired client. Let's look now at each of the major areas of intervention goals for children with DL and discuss some of the considerations necessary to establish individual targets in each one.

Phonology

We talked in the previous chapter about how to decide when and how to assess phonological production. In general, children at developing levels of language are not candidates for speech sound intervention unless their intelligibility is significantly impaired. Because so much phonological growth is going on in the DL period, intervention for particular sounds can usually be deferred until school age, since many speech sound problems resolve on their own by then (Shriberg & Kwiatkowski, 1994). However, if a child is seriously unintelligible, intervention is warranted. Social disvalue and even social isolation, as well as frustration and behavioral and emotional reactions, can occur in children who have difficulty in getting messages across, even if they would eventually outgrow the unintelligibility. Although the specific targets of the intervention in this area will be the acquisition of particular sounds or the suppression of particular simplification processes, we need to remember that the important long-term goal is to increase the client's overall intelligibility. All the issues we discussed in Chapter 3 about being careful to ensure that behaviors learned in intervention generalize to real conversation must be addressed to ensure that phonological production improvement leads to real gains in intelligibility. Kent, Miolo, and Bloedel (1994);

Gordon-Brannan and Hodson (2000); and Morris, Wilcox, and Schooling (1995); discussed a variety of instruments that can be used to evaluate changes in intelligibility in the course of an intervention program.

Although the range of approaches to speech sound intervention is beyond the scope of this text, Williams, McLeod, and McCauley (2010) provide a comprehensive description and evaluation of the bases in evidence of a large number of interventions in this area, categorizing them into three major groups: interventions that focus specifically on speech sound production but assume that errors stem from phonological, rather than motoric sources; interventions that place speech sound production in the broader context of speech perception, language, literacy, and communication; or those that focus primarily on the motor acts involved in speech production.

We need to remember, too, that speech sound and language disorders often co-exist in the same child (Pennington & Bishop, 2009). So assessing syntactic and semantic skills in unintelligible children is always important in order to avoid missing deficits in these areas that are masked by the difficulty in understanding what the client says. When assessment of an unintelligible child indicates that syntactic and semantic deficits are present, it makes sense to address those targets early in the intervention program, rather than waiting until the child is fully intelligible. One way to address them is through input, providing indirect language stimulation, focused stimulation, or auditory bombardment (see Comprehension versus Production Targets, later in the chapter) of the forms we want the child to begin learning. These activities can be supplemented with more direct production activities that control for pronounceability of target words. In general, in accordance with our principle of requiring the client to do only one new thing at a time, we will want to address phonological and semantic/syntactic targets *separately*, not within the same activity. However, Tyler, Lewis, Haskill, and Tolbert (2002, 2003) showed that, when children have both phonological and morphosyntactic deficits, working on morphosyntax leads to changes in both areas. This research suggests that, for children with both speech and language problems, morphosyntactic deficits should be addressed first, followed by work on whatever phonological targets have not resolved in the course of the first segment of intervention.

One further consideration in planning phonological intervention at the preschool level concerns the connection between phonology and metaphonology. *Metaphonology*, or phonological awareness (PA), is the ability to detect rhyme and alliteration; to segment words into smaller units, such as syllables and phonemes; to synthesize separated phonemes into words; and to understand that words are made up of sounds that can be represented by written symbols or letters. These PA skills develop sequentially through the late preschool period (Hodson, 1994; Swank, 1999; Schuele & Boudreau, 2008). Several of these abilities have been shown to be closely related to success in learning to read (Hogan, Catts, & Little, 2005; Scarborough, 2003; Swank, 1994, 1999) and spell (Bourassa & Treiman, 2001; Clarke-Klein & Hodson, 1995; Gillon, 2002; Kirk & Gillon, 2007). Bird et al. (1995), Larrivee and Catts (1999), Pennington and Bishop (2009), and Rvachew et al. (2003) have shown that children with productive phonological problems during the DL period sometimes have trouble acquiring PA and are at risk for developing reading problems. This information suggests that when working with preschoolers who have phonological production problems, incorporating PA activities within the speech therapy may be helpful in preventing literacy difficulties. A few studies have shown that doing so does improve

TABLE 9-1 Milestones of Normal Communicative Development: Preschool Years

Area	Goals
Phonology	Increase consonant repertoire. Increase production of closed syllables. Decrease use of phonological processes. Increase production of multisyllabic words. Increase accuracy of sound production. Increase intelligibility.
Semantics	Increase vocabulary size. Increase use of verbs for specific actions (sweep, slide, bend, fold, etc.). Increase appropriate pronoun use. Increase understanding and use of basic concept vocabulary (spatial terms, temporal terms, deictic terms, kinship terms, color terms, etc.). Increase range of semantic relations expressed within sentences (possession, recurrence, location, etc.). Increase range of semantic relations expressed between clauses (sequential, causal, conditional, etc.). Increase use of appropriate conjunctions (<i>but</i> , <i>so</i> , etc.).
Syntax	Increase sentence length. Increase sentence complexity (use of prepositional phrases, noun modifiers, verb marking, etc.). Increase use of a variety of sentence types (questions, negatives, conjoined and embedded, passives, etc.). Increase use of appropriate auxiliary verbs (<i>can</i> , <i>will</i> , <i>must</i> , <i>have</i> , <i>is</i> , <i>are</i> , etc.). Increase use of copula verbs (<i>is</i> , <i>am</i> , <i>was</i> , <i>were</i> , etc.). Increase understanding of word order in sentences.
Morphology	Increase use of simple morphemes on nouns (plural, possessives, etc.). Increase use of verb markers (tense, number, aspect, etc.). Increase use of higher-level morphemes (<i>-er</i> , <i>-est</i> , etc.). Increase appropriate use of articles (<i>a</i> , <i>an</i> , <i>the</i>).
Pragmatics	Increase use of verbal forms of communication. Increase use of language to achieve communicative goals. Increase flexibility of language forms for various contexts. Increase ability to initiate communication with appropriate forms. Expand range of communicative intentions expressed with a variety of language forms. Increase ability to maintain conversational topics. Increase ability to manage conversational turn-taking, topic-shifting. Begin to use various genres of language (e.g., narration). Increase ability to make and request conversational repair.
Play and thinking	Increase ability to use objects to represent others. Increase use of pretend and imaginative play. Increase play that involves social role-playing. Increase ability to use language to foster abstract thought. Increase ability to use language to negotiate peer interactions. Increase ability to use language to self-monitor and inhibit aggressive behavior.
Preliteracy	Listen to stories; talk about pictures and events in books. Look at books independently; orient book properly, turn pages. Recognize parts of books: pages, title, orientation of print. Recognize words in print (e.g., find first word on a page, count words on a page). Begin to develop metalinguistic and phonological awareness: Develop awareness of rhyme. Count syllables in words. Sing alphabet song; identify letters. Begin to be able to segment words into syllable and sound units. Know what a <i>word</i> is. Identify words that start/end with the same sound. Count sounds in words. Match sounds and letters.

both speech and PA in children with speech delays (e.g., Hesketh, Adams, Nightingale, & Hall, 2000; Kirk & Gillon, 2007; Van Kleeck, Gillam, & McFadden, 1998). Hesketh (2010) summarizes this literature, concluding that children as young as 4 can be taught PA, that PA instruction improves literacy performance especially when alphabet letters are taught as well, and that including PA in a speech program leads to as much improvement in speech as is seen when the focus is speech only. Since incorporating PA activities in

speech therapy may help shore up preliteracy weakness in children with speech sound disorders, clinicians can consider including PA activities in speech intervention for preschool children with reduced intelligibility. Some suggestions for doing this appear in [Box 9-1](#). Kiewel and Claeys (1999) and Noble-Sanderson (1993) also provided phonology programs built around storybook activities that integrate speech sound remediation with the development of PA for children at the DL level.

BOX 9-1 Phonological Awareness Activities for Use in a Phonological Production Program at the Developing Language Level

DEVELOPING RHYMING SKILLS

1. Using a "pocket chart," present a card with a picture of a word containing one of the client's target sounds in one pocket in each row. Have the client find a picture, from a set the clinician provides, for a word that rhymes with each, and place it in the pocket next to its "rhyming buddy."
2. Prepare a set of cards with pictures whose names contain the client's target sounds. Have some rhyming and some non-rhyming pairs in the set. Present a pair of pictures. Name each picture, and then ask the client whether the two rhyme.
3. Make up rhymes for words targeted in the speech sound program.
4. Use rhyming words to work on sounds in final position. Point out the rhymes to clients. Encourage clients to make up new words with the same ending. Accept nonsense words.
5. Use written forms of target rhyming words as cues, along with pictures. Point out that the rhyming words have the same letters at the end in the written form.
6. Write "word family" stories with clients. Choose a rhyming-word family containing a target sound in final position (such as the *us* family for work on final /s/). Have clients make a list of words in that family, and write the list on the board (e.g., *us, bus, Gus, fuss*). Encourage clients to make up a silly story with these words (e.g., "Gus got on the bus with us. He made a big fuss. The bus driver put us off the bus.").
7. Write down the story, and have clients illustrate it. Point out the letter for the target sound at the end of the word. Have the clients "read" the story to each other, to the clinician, and to parents.

DEVELOP AWARENESS OF SYLLABLES

1. Have students tap or clap out the number of syllables contained in words targeted in the speech-remediation program.
2. Play "how many parts" with target words. Include both one- and two-syllable words with target sounds. Have cards containing pictures or cues for each target word. Have clients pick out all the cards for words with only one "part" and pronounce those. Then have clients pick all the cards for words with two "parts."

DEVELOP AWARENESS OF FIRST/LAST SOUNDS IN WORDS

1. Create cards containing pictures of words that start (or end) with two or more of the child's target sounds. Have the child sort the cards into piles that match in terms of first (or last) sound. Remind the child of the first (or last) sound in the first pile of cards; then have him or her say each word in the pile. Repeat for the other piles. (This activity works well when the child confuses two sounds or says two different sounds the same way; sorting can be done for just the two sounds that are interchanged). Ready-made cards can be found at www.rockingham.k12.va.us/sound_sorting/sound_sorting_menu.htm.
2. Prepare a set of cards with pictures whose names contain the client's target sounds. Have some pairs that begin with the same sound and some that do not in the set. Present a pair of pictures. Name each picture, and then ask the client whether the two begin with the same sound.
3. A puppet is introduced and named (for example his name could be Sam, if /s/ is one of the client's target sounds). The client is told the puppet likes words that begin with the same sound as his name. The client is asked to say as many words as he or she can that begin with this sound.
4. Use the target sound in initial position. Play an "I spy" game in which clinician and client must "spy" words that begin with the target sound (some may be "planted" around the room) and say them.
5. Display a large card with the alphabet letter or letters representing the target sound (e.g., S or SH). Have the client look through old magazines for pictures of words that begin with the target sound. Give them a bright marker to use to write the letters that represent the target sound on a magazine picture, as they say the word for the picture.
6. Use storybooks that include multiple examples of the client's target sound (e.g., *Hop on Pop* [Geisel & Geisel, 1963] for final /p/, or *The Very Busy Spider* [Carle, 1984] for initial /sp/, which appears on every page in the word *spin*). Read the book to the clients. Then read it again, stopping when a word with a target sound appears, allowing the client to say the target word. Point to the printed word as the client "reads" it. Later, have clients search for these "magic" words with their target sounds themselves, and have them point to the words in the book as they say them. Examples can be found at <http://crokebeck.tripod.com/articbks.htm/homepage.html>.
7. Have clients make up silly words that begin or end with target sounds. Let them use invented spelling to write the words, or the clinician can write the target sound for them and let them "guess and go" to spell the rest. Clients can draw pictures of their silly words and put the pictures together in a book that they can "read" to their family to practice their target sounds.

DEVELOP PHONOLOGICAL SYNTHESIS SKILLS

1. Use continuum consonants (/m,n,s,r,f,h,l,v,w,z/) first for synthesis work, since they can be prolonged more naturally. Choose a word family (e.g., *am*). Write the family on a card. Then write several continuum consonants on separate cards, including ones the client is targeting in the intervention program. Place a consonant card by the word family and illustrate blending the consonant with the family to form a word or nonsense word (e.g., *s-am*). Help the client to form various words and nonsense words by combining the consonants with the word family. Let the client write the words formed, and draw pictures to illustrate them. Silly creatures can be used to illustrate the nonsense words.
2. Using several word families worked on in this way, the clinician can say a word and ask the client to find the two cards (consonant and word family) that spell the word being said. Clients can take turns saying words and having the clinician or other client spell out the word with the cards.

Semantics

Children with developmental language disorders (DLD) appear to acquire words in comprehension much the way typically developing children do, but may need to hear a new word twice as many times as other children before comprehending and independently using the new word (Gray, 2003; Rice, Buhr, & Oetting, 1992). Children with language impairments also have particular difficulty in the acquisition of words to talk about cognitive states, like thinking (Lee & Rescorla, 2008), with verb vocabulary (Loeb, Pye, Redmond, & Richardson, 1996) as well as the use of verb particles (pick *up*, put *down*, etc.) (Watkins, 1994). In addition, children with DLD are less able to identify semantic features than their peers with normal language. These findings suggest that children with DLD have broader difficulties with receptive vocabulary than simply a reduced ability to acquire labels; they may need enriched input with repeated opportunities to see connections between words and their referents in order to learn new lexical items. Gray (2005) found that providing both semantic and phonological cues aided learning new words by preschoolers with DLD. This suggests that as we introduce new vocabulary, it makes sense to highlight both semantic (“*triangle* is the name of this shape; it’s a shape that has three sides; a piece of pizza is shaped like a *triangle*”) and phonological (“*triangles* have three sides and *tri an gle* has three parts; *triangle* starts with the same sound as *toy*”) aspects of the word.

Owens (2004) provided a list of likely vocabulary targets for the DL period. These appear in Appendix 9-1. But Neuman and Dwyer (2009) point out that, because of the known relationship between complexity of vocabulary in preschool and reading achievement as much as 2 years later, it is important not only to teach basic words, but to expose students to rare words, as well. Ruston & Schwanenflugel (2010) showed that conversational input from an adult emphasizing use of rare words, linguistic recasts, and open-ended questions increased expressive vocabulary in children with low levels of vocabulary development. Paul (2011) gives guidelines for providing this kind of enriched input. These techniques can be important not only for preschoolers with DLD, but also for children who have impoverished vocabularies for other reasons, such as limited English proficiency, as well.

You’ll notice from the list in Table 9-1 that this area contains targets not only in vocabulary, which is, of course, important, but

Both speech and language skills are often targeted at the developing language level.

also in the kinds of semantic relations conveyed within and between clauses of sentences. In the early DL phase, an important goal of intervention is helping children broaden the range of ideas they can talk about. Toward the end of this phase, we want to help clients make their sentences more efficient by combining ideas, or *propositions*, within a sentence to convey specific semantic relations between clauses. Assessment information collected during the standardized and informal portions of the evaluation should guide us toward the level of semantic complexity to target within the client’s language.

Remember that, when we’re planning targets and methods of intervention for language, we artificially segment language into components such as semantics and syntax. But really, when we target a particular sentence type, that sentence is, of course, conveying a meaning. Similarly, when we target a particular meaning for expression, that expression takes a syntactic form. So in practice it is hard to separate the semantic and syntactic components of sentences. When we plan intervention targets and activities involving semantic and syntactic expression in sentences, the main thing to remember is the principle we talked about in Chapter 3: only one new thing at a time. When asking a child to produce a more complex sentence form, we want to be sure it encodes a meaning that the child has already expressed in a simpler way. When asking the child to talk about a new meaning or combine new meanings in sentences, we need to control for syntactic complexity, making sure that the form we want the client to use in producing this new meaning is already within the production repertoire.

Syntax and Morphology

Syntactic and morphological targets of intervention are perhaps the most obvious goals of the DL period. Working on production of grammatical forms is among the most traditional aims of language intervention and one most speech-language pathologists feel comfortable targeting. We ought to be aware of two points in selecting our grammatical intervention goals for children in the DL period, though. First, although grammatical goals are virtually always appropriate for children in this period, the need to improve syntax should not lead us to ignore the other areas of intervention that also are important. Many children with grammatical deficits also have unintelligible speech, small vocabularies, word-finding problems, limited preliteracy skills, or difficulties in using language in the service of play, thinking, and conceptual development. These needs ought to be addressed, too.

A second thing we need to bear in mind is that there are some typical patterns of grammatical deficits in children with language impairments (that is, some aspects of syntax and morphology are more likely to show deficits than others). Knowing what these are can help us to zero in on these areas in the assessment process. Let’s look at what these typical grammatical problems are for children in the DL period.

Bound morphemes are particularly difficult for children with language problems of a variety of etiologies (Goffman & Leonard, 2000; Leonard, 1997; Rice, Warren, & Betz, 2005; Rice & Wexler, 1996). Auxiliary verbs and small, closed-class morphemes, such as articles (*a*, *an*, *the*) and pronouns (e.g., *I*, *you*, *he*, *she*, *we* *they*), also seem to cause particular difficulties for children with language impairments (Bates, 2003; Beverly & Williams, 2004; Eisenberg, 2005; Rice, Warren, & Betz, 2005). Irregular past morphemes and use of *-ing* endings seem to be a relative strength (Redmond & Rice, 2001; Rice, Warren, & Betz, 2005). Studies of children with slow expressive-language development as toddlers who show chronic delays through the preschool years (Paul & Riback, 1993;

Rescorla & Roberts, 2002) substantiate this pattern. Difficulties with the elaboration of sentences through complex sentence production have also been reported (Eisenberg, 2005; Thordardottir & Weismer, 2001). It would appear, then, that verb marking with auxiliaries and inflections, closed-class morphemes, pronoun use, and the acquisition of complex sentences are areas in which children with language disorders can be expected to show particular difficulties during the DL period. These areas would be especially appropriate targets for intervention, when, of course, these deficits are documented by the assessment process. Fey, Long, and Finestack (2003) discuss some guiding principles for selecting goals for syntax and morphology during the DL phase. These are summarized in Table 9-2.

Comprehension versus Production Targets

We talked in Chapter 3 about the issue of targeting comprehension as opposed to production in the intervention program. There we said that, when assessment indicates a form or meaning is comprehended but not produced, production training is indicated. Lahey (1988) emphasized the fact that equivalent comprehension and

production responses are often not present in normal language learners. She argued that a child should be exposed, through multiple meaningful exemplars in the input language, to forms and meanings that are not in the comprehension repertoire. But she concluded that comprehension responses, such as pointing to contrastive stimuli, do not need to be trained before production of the forms is targeted. Guided production activities appear to facilitate both comprehension and production of new meanings and forms in children.

Recall, too, that Chapter 3 included some suggestions about targeting comprehension versus production performance in the intervention program. Production training should be a high priority for forms and meanings for which the child demonstrates comprehension. For forms and meanings that the child does not yet appear to comprehend but that are chosen as intervention targets on the basis of other considerations we've discussed, an input component should be part of the intervention plan. This might include focused stimulation or indirect language stimulation activities that provide multiple opportunities for the clinician to demonstrate use of the structure in context.

TABLE 9-2 Principles of Goal Selection for Grammatical Targets in the Developing Language Period

Principle	Example
1. Main goal of grammatical intervention: help the child understand and use syntax in the service of communication.	When <i>is (verb)-ing</i> is used 80% correctly in clinician-directed formats, begin using focused stimulation or indirect language stimulation to generalize the form to more natural contexts; evaluate production in these contexts before considering goal met.
2. Goal attainment must be measured in real communication contexts (conversation or narration).	
3. Producing a target at 90% correct in a clinician directed activity is not enough; form must be used in real communication.	
4. Grammar is rarely the only aspect of language that needs to be targeted in an intervention program for DL children, who often have small vocabularies, social problems, and often grow to be children with reading disorders.	For work on auxiliary verbs, use <i>Green Eggs and Ham</i> (Seuss, 1956) as one practice context. After multiple readings, allow the child to fill in verb phrases. Point to the words as the child says them. Ask him or her to identify words that rhyme.
5. Children with most obvious errors in sentence structure are likely to need support in other areas of communication: • Preliteracy • Pragmatic skills • Vocabulary	
6. Contexts such as guided play, mediated conversation, and storybook sharing should be considered.	
7. Select goals that trigger changes both within and outside the therapy context: • Look for, not just single goals, but ways to change patterns of language.	If a child says <i>me/I</i> , rather than working on just "I," target the distinction between subjective and objective pronouns more generally. This way, the child can learn about a broad range of forms rather than just one.
8. Base goals on "functional readiness" and the communicative need for targeted forms. Target grammatical forms: • That the child uses correctly on occasion • For which obligatory contexts appear in the child's language. These are more likely to show change than are forms the child does not have any experience with.	If a language sample shows several obligatory contexts but no correct question reversals, production of occasional <i>be</i> verbs, and no contexts for <i>can</i> or <i>will</i> , target <i>be</i> and question reversals first.
9. Children with language disorders need more experience than others to master grammatical forms: • Focus on emerging forms to help move them toward mastery more efficiently. • Provide frequent and intensive exposure and practice of these forms.	

Adapted from Fey, M., Long, S., & Finestack, L. (2003). Ten principles of grammar facilitation for children with specific language impairments. *American Journal of Speech-Language Pathology*, 12, 3-15.

Auditory bombardment is another viable input option. Hodson and Paden (1991) advocated using this approach to facilitate phonological development. They argued that phonological skills are acquired, at least in part, by listening. This implies that children need to listen carefully and often to the sounds they are being asked to produce. Kouri (2005) showed that, in a vocabulary training program, auditory bombardment had effects comparable to an elicited imitation program on the use of target words in real communication. Hodson and Paden suggested having children listen to a list of target words. It is worth noting that Flexer and Savage (1993) showed that both children with language impairments and those with normal hearing showed improved attention when assistive listening devices were used to improve signal-to-noise ratios during a testing situation. There is, then, some evidence that these devices might be useful in auditory bombardment activities for children with language needs. In auditory bombardment activities, the child simply sits and plays quietly with nondistracting material such as Play-Doh as the clinician reads the list of words. Although traditional auditory bombardment uses simply a list, it might, alternatively, consist of listening to a story that contains numerous examples of target forms. Hoffman, Schuckers, and Daniloff (1989) provided poems and stories that are weighted with examples of phonological targets. Cleave and Fey (1997) discussed the development of “syntax stories” created to provide auditory bombardment of particular target forms within a story context. Box 9-2 gives an example of an excerpt from one of their “syntax stories.” Regardless of whether a list or a story is read, the auditory bombardment segment generally makes up about 5 minutes of the intervention session. The child is not required to perform any discrimination activities, only to listen. Such activities also make excellent “homework” assignments for families interested in working on targets at home. They can easily be substituted for the child’s usual bedtime story and don’t require the parents to judge or correct the child’s communication. If follow-up activities, such as illustrating the clinician’s “syntax story” and rereading it with cloze procedures, are added, as Cleave and Fey suggest, even more benefit can be derived from the auditory bombardment.

Approaches that facilitate comprehension, such as focused stimulation, indirect language stimulation, and auditory bombardment, should be presented along with activities that elicit production of target forms and meanings. Such a combination of approaches can help to ensure that clients can both understand and use the forms and meanings being taught. It is *not* necessary,

Assistive listening devices can improve signal-to-noise ratios in speech-language intervention.

though, to wait until the child demonstrates comprehension in pointing or discrimination activities before trying to solicit the use of target forms and meanings.

Pragmatics

Before we discuss intervention approaches for pragmatics, we want to clarify our view of the role of pragmatics in the intervention program for children with DL. Contemporary thought about language acquisition emphasizes the central place of pragmatic functions. That’s because we see language not as a set of rules to be learned, but as a tool for communication. Learning language is not just learning sounds, words, and sentence structures; it’s also learning how to get things done in the real world with those sounds, words, and sentences. The study of how language is used in the context of communication is what is meant by *pragmatics*.

Pragmatics is just as important for thinking about language intervention as it is for acquisition. There are two ways to add pragmatics to our practice. The first is to generate a set of pragmatic targets or objectives for intervention. We could categorize children according to their pragmatic skills, identify their pragmatic deficits, and teach them to use whatever pragmatic behaviors they are lacking. Targets might include skills such as turn-taking, topic maintenance, and register variation. The problem with this approach is that we can’t really isolate these pragmatic skills from the syntax and semantics on which they rely. Unless we are teaching the earliest preverbal communication skills to a nonspeaking child, a client must use sounds, words, and sentences to achieve pragmatic targets.

A better way to incorporate pragmatics in the intervention program, in our view, is the method advocated by Craig (1983) and Marton (2005). They argued that, rather than defining pragmatics as an additional set of rules that the child needs to learn, we are wiser to see pragmatics as the context in which intervention takes place, and to make sure that each new form learned is practiced in a variety of pragmatic contexts. That is, rather than teaching turn-taking as a separate skill, we would develop activities in which the client could take turns with the clinician using a linguistic form that was a target of intervention. Or, instead of teaching topic maintenance as a separate skill, we would give the client an opportunity to talk about a topic of interest for an extended number of turns, using newly acquired forms. We could, for example, ask a client who is working on past-tense forms to describe each step used to, make the pudding now being shared with a parent who was not

BOX 9-2 An Excerpt from “Dad’s Bad Joke”

TARGET: ARE

Neil and Warren liked to play in the attic. It was fun up there, but it was a little scary, too. They always turned on the light so they could see. One day Neil and Warren started to go upstairs.

“Where *are* you going?” asked Dad.

“*Are* you going to the attic?”

“Yes, we *are*!” shouted Warren.

“Neil and I *are* going up now.

We *are* going to play up there.”

“Oh you *are, are* you,” thought Dad.

present during its preparation. If the child strays from the topic, the clinician could provide a prompt to return to describing the sequence, such as, “Wait a minute, weren’t you saying how we made the pudding? ‘We stirred the milk,’ you said. Then what happened?”

Must these pragmatic contexts be present in every intervention activity? We don’t think so. In fact, in our view they should not be, because that would lead us to violate Slobin’s (1973) principle of one new thing at a time. If past-tense forms are just being elicited, we won’t want to ask the child to use these new forms to fulfill a new function such as maintaining a topic—not until the new form has been somewhat stabilized. A more reasonable approach, to our way of thinking, is to incorporate pragmatic contexts into the intervention plan for every objective, but not for every activity. Some activities should be devoid of pragmatic context, to allow the child to focus attention on the linguistic objectives. Other activities can be designed to help clients use the new structures in real pragmatic contexts.

The real communicative contexts chosen should be based on the pragmatic assessment data. Suppose Rachel, for example, had been evaluated with Prutting and Kirchner’s (1983) Pragmatic Protocol and had been found to have deficits in conversational repair. Once appropriate question forms had been added to her repertoire by means of semantic and syntactic intervention, these forms might be put to use in the context of conversational repair. The clinician might feign misunderstanding of something Rachel said, model asking a clarification question, and encourage Rachel to answer it to repair the breakdown. The clinician might then give a mumbled or otherwise unclear message and encourage Rachel to ask a question to get clarification. In this way the client can be helped to use new semantic and syntactic forms in pragmatic contexts identified as problem areas as a result of the pragmatic assessment. Brinton and Fujiki (1989, 1995) provided detailed procedures for this aspect of intervention.

Play and Thinking

A variety of studies (summarized by DeKroon, Kyte, & Johnson, 2002; Johnston, 1994; Leonard, 1997; Mainela-Arnold, Evans, & Alibali, 2006; Rescorla & Goossens, 1992) have shown that children with language problems perform less well than normally speaking peers on a variety of cognitive tasks, including symbolic play, even when they score within the normal range on nonverbal intelligence tests. During the preschool period in normal development, as Vygotsky (1962) pointed out, language begins to help to structure thought, and thought is carried out primarily in the modality of language. One of the major accomplishments of normally developing children in the preschool period is the beginning of the integration of language and cognitive processes, each feeding off and growing out of the accomplishments of the other. Much learning about concepts, categories, and the physical world during the preschool years goes on through the medium of language, instead of through direct perception and experience, as it did in the sensorimotor period. Children structure symbolic play through language both when they play alone (often talking out loud to pretend playthings) and when they play with peers (often negotiating the roles and rules of the play by talking about them: “I’ll be the baby and you be the mommy, but be a nice mommy and don’t scold me when I spill my bottle.”). It should not be surprising, then, that children with language problems would begin to lag behind in some of these skills that are so intertwined with language.

When working with children at DL levels, we want to incorporate activities that encourage the child to use the language being learned to structure pretend play, solve problems, and explore new ideas. Moreover, play is an important context in which such problem solving and exploration can take place. As children develop more elaborated and flexible forms of language, these can be used for more mature and imaginative play. Again, play and thinking may not be direct targets of the intervention. Like the social skills in the pragmatics area, we can use play and problem solving as contexts in which the child can practice using new forms and meanings. By providing contexts in which the child can use recently acquired forms for new purposes, we accomplish two things. First, we help the child to generalize the intervention targets to meaningful situations. Second, we move the child into the zone of proximal development, providing a scaffold that helps the child to use language to achieve new levels of symbolic and conceptual development with our models and support. Play and problem-solving are important contexts for extending the child’s use of newly emerging forms and meanings. As we proceed through the intervention program, we will want to build in some of these rich contexts, in addition to the more constrained settings in which forms and meanings may be elicited initially.

Preliteracy

Many preschoolers with language delays develop problems in learning to read and write, even when their oral language problems appear to resolve (Skibbe et al., 2008; Stothard, Snowling, Bishop, Chipchase, & Kaplan, 1998). Research reviewed in the National Joint Committee on Learning Disabilities (2007) Technical Report 12, *Learning Disabilities and Young Children: Identification and Intervention*, has shown that deficits in phonological processing can be a major obstacle in learning to read. This research suggests that strong oral language, phonological awareness, understanding about print, alphabet knowledge, invented spelling, rapid naming, and a child’s ability to write his or her own name prior to kindergarten are all indicators of literacy success in school (National Early Literacy Panel, 2005). And research has shown that the most effective interventions for children at risk for later reading problems focus on oral language instruction in preschool and kindergarten, and include explicit teaching of phonemic awareness, letter-sound relationships, vocabulary, and language comprehension (Dickinson, McCabe, & Essex, 2006; Lyon, 1999).

Increasingly, and for good reason, speech-language pathologists are being expected to address these areas of instruction in preschool programs for children at risk, and to promote preliteracy development in these children (American Speech-Language-Hearing Association [ASHA], 2000b; Justice & Ezell, 2004; National Joint Committee on Learning Disabilities, 2007; Wallach, Charlton, & Christie, 2009). That’s because SLPs are usually the professionals with the deepest understanding of phonological processing and the broadest knowledge about the connections between reading and oral language (Spencer, Schuele, Guillot, & Lee, 2008) and have much to offer others who work with young children when designing pre-literacy programs not only for those at risk, but for all children in the preschool classroom. When working with children in the DL phase, incorporating pre-literacy goals and contexts is an important part of our direct work with clients, and can also serve as a fruitful basis for collaboration with classroom teachers and care-providers. Kaderavek and Justice (2004) outlined the major goals of pre-literacy development during the DL period. These appear in Table 9-3. The goals can be divided into three

TABLE 9-3 Domains for Preliteracy Intervention

Domain	Instructional Goals	Example Activities
Phonological awareness	Segment words in sentences.	Teacher has children in group clap for each word in a poem.
	Segment syllables in words.	Teacher has children stamp once for each syllable in words.
	Produce rhymes.	Teacher rereads familiar rhyming book, and has children fill in blanks ("Stop, you must not hop on ____!").
	Synthesize words from syllables.	Teacher introduces "robot" puppet who only speaks syllable by syllable ("mo tor cy cle"). Children must guess word he means.
Print concepts	Synthesize words from sounds.	Teacher introduces "alien" puppet who only speaks sound by sound ("/d/ /a/ /g/"). Children must guess word he means.
	Identify words with same beginning/end sound.	Teacher has children stand up, clap, or wave each time they hear a word with a target beginning/ending sound in a story or poem being read.
	Book reading conventions.	Teacher occasionally holds book upside down or backwards; children demonstrate correct orientation.
	Understand metalinguistic terms (word, letter, sound).	Adult demonstrates elements from storybooks ("Here's a long word; Do you see this letter?")
Alphabet knowledge	Link text to experience.	Teacher encourages children to make personal connections to storybook themes ("Sam-I-Am doesn't like Green Eggs and Ham. How many of you like eggs? Ham? How many don't?")
	Recognize environmental print.	Teacher shows photographs of print in the environment or from field trips; asks children to find the word that says "Stop," etc.
	Alphabet song.	Teacher begins each day w/choral singing of alphabet song, pointing out each letter on a chart as children sing. Eventually, children are given turns to do the pointing.
	Recognize own name in print, and the letters in it.	Children's names are used as labels throughout the classroom; they are encouraged to identify their name on their cup, coat hook, etc., and point out the letters of their name.
Narrative and literate language	Recognize letters in environmental print.	Children are given a card with a letter and encouraged to find words on a field trip or in photos of street scenes that start with their letter.
	Sort upper and lower case letters.	Toys are labeled with letters; children are encouraged to place toys in boxes with matching letters.
	Write own name.	Children are given multiple opportunities to form their names with plastic letters, tiles, letter cards, as well as to trace and write their names.
	Retell stories heard.	Children reenact stories heard, with simple costumes and props.
	Use causal conjunctions in story retells.	Children are asked to respond to questions about why events in the story took place and are prompted to use causal language, such as "because."
	Use mental and linguistic verbs in story retells.	Teacher encourages students to talk about what characters are saying and thinking in stories they have heard.

Adapted from Kaderavek, J., & Justice, L. (2004). Embedded-explicit emergent literacy intervention II: Goal selection and implementation in the early childhood classroom. *Language, Speech, and Hearing Services in Schools, 35*, 212-228.

major categories: *phonological awareness*, *print and alphabet knowledge*, and *literate language*.

Phonological awareness goals should be familiar by now: they include the ability to count syllables and sounds, to identify rhymes and words that start/end with the same sounds, and to manipulate sounds in words ("What's *fun* without the /f/?"). We talked already about ways to build emerging literacy skills by incorporating PA activities within the speech sound program for children at the DL level. But PA is important for children with other language delays, as well as for children at risk for reading failure due to vulnerabilities such as limited English proficiency, cultural differences, or poverty. SLPs have important roles to play in getting preschoolers ready to read, both as clinicians for children with documented language disorders, and as consultants for improving pre-literacy instruction for all children in the preschool classroom.

In addition to PA, however, Kaderavek and Justice (2004) argue that skills related to print and alphabet knowledge are also crucial to emergent literacy development. These skills are sometimes called *literacy socialization* (Serpell, Sonnenschein, Baker, &

Ganapathy, 2002; Snow, 1999), and involve understanding how books work and how print represents speech through written language units like letters, words, and punctuation. Activities that provide instruction and practice in literacy socialization are also important aspects of a pre-literacy program.

Finally, the third aspect of pre-literacy instruction has to do with the development of literate language. Literate language is the style used in written communication and is typically more complex and less related to the physical context than the language of ordinary conversation. We'll say a lot more about literate language in Chapter 10, but for now, we need to be aware that the ability to understand literate language is the "third leg" of a comprehensive pre-literacy program. As we work with children in clinical sessions, with teachers as consultants, or in classrooms as collaborative interventionists, we can introduce literate language forms to preschool children by exposing them to stories, poems, plays, and other texts that exemplify this more elaborate language style, and giving them the opportunity to interact with these texts by hearing them, acting them out, retelling them, and relating them to personal experiences.

SLPs often work on pre-literacy instruction in preschool and kindergarten classrooms.

Kaderavek and Justice (2004) review research that demonstrates that both for children with language impairments, and for those at risk for reading problems due to poverty or language differences, explicit pre-literacy instruction in these areas, which is embedded in preschool classroom routines and activities, has positive effects on children's readiness for learning to read. Preschool programs that provide direct instruction and practice in name recognition and writing, alphabet recitation and recognition, awareness of book and print conventions, and PA games have been shown to lead to significantly greater growth in emergent literacy skills than programs that merely expose children to books and print (Justice, Chow, Capellini, Flanagan, & Colton, 2003; Justice & Ezell, 2004). In addition to incorporating PA within speech intervention for children with speech delays, SLPs can also consult with teachers on how to address emergent literacy for all children in the preschool classroom. SLPs can identify the relevant areas of pre-literacy to address, using guidelines like those in Table 9-3; assist in designing lessons to provide instruction and practice of these skills in high interest activities tied to classroom themes; work alongside the classroom teacher to present the instruction and provide extra support to children who are having difficulty; and carefully monitor children's participation and progress in the classroom activities to identify those who might need more intensive intervention in these areas (Gillam & Justice, 2010; Kaderavek & Justice, 2004).

Intervention Procedures for Children with Developing Language

In Chapter 3, we discussed three major methods of intervention identified by Fey (1986): clinician-directed (CD), child-centered (CC), and hybrid. As we discussed in Chapter 3, the goal for us as clinicians is not to choose one method and use it consistently, but to have a repertoire of methods available that we can match to the needs of individual clients and the particular goals being addressed. In this way we can maximize the efficiency of our intervention and have the greatest chance that it will generalize to the client's everyday communication. Let's look at each of these methods to see how they might be applied to the child with DL.

Clinician-Directed Methods

In Chapter 3, we looked at a variety of clinician-directed approaches geared for the DL period. These included drill; drill play; Leonard's (1975a) CD modeling; and Lee, Koenigsnecht, and Mulhern's (1975) *Interactive Language Development Teaching*. There also are a variety of commercially available intervention packages, including some computer software, that use a CD approach to intervention for targets within the DL phase. Remember that CD approaches are highly effective in eliciting forms in production that the child has not used before or has used very infrequently. When initial elicitation of new forms is the goal, CD approaches make good sense for clients who can tolerate them. The weakness of CD approaches is their failure to generalize to real communication and their tendency to place the child in a passive respondent role. There are two ways to address these problems. One is to follow Fey's (1986) advice and use the techniques outlined in Chapter 3 to increase the naturalness of CD activities. The second is to supplement CD approaches with other methods that give the client an opportunity to practice newly acquired forms in assertive roles and in the service of genuine communication. Let's look at some examples of CD approaches that might be used for several of the typical goals of intervention at the level of DL.

Phonology Speech Sounds

One issue that often arises in phonological training is the question of whether to provide discrimination drills in which the child must identify pictures of words containing contrasting sounds (toe/sew) before production practice begins. This practice has been controversial, but recent research (Rvachew & Grawburg, 2006; Wolfe et al., 2003) suggests that discrimination training is helpful *only* if the child fails to discriminate sounds on which production errors appear, prior to therapy. For these sounds, active discrimination drills worked better than auditory bombardment in increasing discrimination ability. But for sounds the child could discriminate at the beginning of training, additional discrimination training showed no positive effects. These findings suggest that assessing discrimination of sounds in error should be part of the assessment for speech delays and the use of discrimination drills should be reserved for only those sounds the child has been shown to have difficulty differentiating.

Articulation drills are a standard part of traditional intervention for speech disorders. Shriberg and Kwiatkowski (1982a) showed that drill was effective for improving phonological production in children in the DL period (even though neither clinicians nor preschool children liked it very much). *Contrastive drills* are one particular kind of drill often used in phonological intervention for children with DL. Contrastive drills involve developing lists of pairs of words in which the two words in each pair differ in specific ways. In a *minimal pairs* approach, two words that differ by only one feature of the target phoneme are presented for contrast (Baker, 2010; Saben & Ingham, 1991; Weiner, 1981). For example, if stopping of fricatives is a pattern being targeted, a list of pairs of words would be developed in which one word contained a fricative and a contrasting word contained the corresponding stop. Examples would be *sew/toe*, *zoo/do*, *fat/pat*, and *nice/night*. The client is asked to say each pair of words. The hope is that having the contrasting words in the same context will encourage the client to differentiate between them, preferably by suppressing the phonological pattern that would make them homonymous. The *maximal opposition* (Gierut, 1990) or multiple oppositions (Williams, 2010)

approach also opposes pairs of words, but this approach contrasts words that differ maximally on the target phoneme, so that the contrasting words differ not just on one feature of the target phoneme but on several. Using stopping of fricatives as our example target pattern again, a maximal opposition approach would contrast pairs such as *sew/no*, *zoo/moo*, *fat/cat*, and *nice/nine*. Lists of words for use in contrastive drills for various phonological process targets have been published by Elbert, Rockman, and Saltzman (1980) and Godar, Fields, and Schreiber (2004). Kuster (2010) provides additional internet resources for finding these lists. Additional CD approaches for speech sound treatment can be found in Williams et al. (2010).

Drill play is often a preferred form of CD intervention at this level. The production practice segment of the Cycles approach, discussed by Prezas and Hodson (2010), uses a drill play format. These authors offered several possible drill play activities that can be incorporated into the production practice phase of phonological intervention. All the activities involve the use of small cards, each with a picture drawn by the client that represents one of the words containing the target phoneme or sequence that is used in the practice session. Some example activities from Hodson & Paden (1991) include the following:

1. *Hide and seek*. The clinician hides the cards in obvious places around the room; the client says each word as he or she finds the card.
2. *Safari*. Each card is clipped to a picture of an animal. The client uses binoculars (which may be made from two toilet-paper tubes taped together) to find each animal and says each word on the card attached to it.
3. *Sack ball*. Large, open shopping bags, each with one of the client's cards taped to it, are placed around the room. The client throws a softball into a bag and then names the card on that bag. The game is continued until the client has thrown at least once into each bag.
4. *Buried*. The client's cards are buried in sand or foam peanuts. The client names each card as it is unearthed.

Drill play activities like these can, of course, be used for intervention on targets in other areas as well. "Safari" might be used to work on color words, for example. The client could be required to name the color of each animal or a piece of construction paper it holds in its mouth as the animal is sighted through the binoculars. "Sack ball" could be used to drill the client on *is (verb)-ing* or copula sentences by attaching a picture to each sack that depicts an *is (verb)-ing* ("A boy is jumping") or copula ("It is a dog") sentence. The client would be required to say the target sentence as the ball is thrown into each sack.

One important point to consider in developing articulation drills for children in the DL period was raised by Storkel and Morrisett (2002). They summarize research showing that, like younger children, children of preschool age and older show strong relationships between lexical and phonological development. This means that when working on phonological targets, the words in which those targets appear are important to consider. Storkel and Morrisett's review suggests that words used frequently in the language facilitate phonological acquisition. Clinicians can use sources such as Kučera and Francis (1967) or Wiktionary's lists of 100, 200, and 1,000 most common English words (http://en.wiktionary.org/wiki/Category:1000_English_basic_words) to find words with target sounds that are used frequently in everyday speech.

Shriberg, Kwiatkowski, and Snyder (1990) presented a computer-assisted format for drilling articulation performance. They showed

that, although computer-assisted modes of intervention were engaging to most children, they were neither more effective nor more efficient than traditional forms of CD intervention. They suggested that computer-assisted methods are probably most useful in keeping children engaged in later phases of the intervention process when newly acquired forms are being practiced and stabilized, but that they are less effective at initial stages when new forms are first elicited. Other examples of computerized articulation programs include *The Articulation I, II, III* (San Luis Obispo, CA: LocuTour Multimedia), *Artic Games & More* (San Luis Obispo, CA: LocuTour Multimedia), *Speech Sounds on Cue* (Blacksburg, VA: Bungalow Software), *Acorn's Gold Mine: An Interactive CD-ROM Game for Articulation and Phonological Skills* (DeKalb, IL: Janelle Publications), *Say-N-Play* from Advance Games, LLC, and *SATPAC* (Systematic Articulation Training Program Accessing Computers) (Fresno, CA: SATPAC Speech, LLC). Even at the late phases, though, the computer-assisted modes were only as good as the traditional ones, not any better. Schery and O'Connor (1995) discussed similar findings in the areas of semantics and syntax. If children like computer-assisted drill, we should by all means use it if it is available. But if intervention software is not available or if financial considerations force us to make a choice between a software package and some other useful intervention material, we should not despair. Many equally effective and engaging methods of intervention are available to us.

Phonological Awareness

As Gillon (2007) highlights, PA is a crucial element in children's development of reading, writing, and spelling skill; and instruction in PA significantly improves achievement in children at risk for reading problems and those with reading disorders. There are many ways to provide PA instruction to young children, but drill play activities that focus attention on the sound structure of words are some of the most common approaches. There are a variety of commercially available approaches, including complete curricula (e.g., Adams et al., 1998; Blachman et al., 2000; Gillon, 2000a), as well as handbooks of classroom activities (e.g., Fitzgerald & Yuh, 1997; Spector, 2009). SLPs who work in preschool classrooms can provide this intervention in a variety of formats, including teaching collaborative "guest" phonological awareness lessons to the whole group, doing small group work within the classroom for students on IEPs or those identified as having difficulty with PA in an RTI framework, as part of individualized language intervention for children on IEPs, or as consultative suggestions to classroom teachers. Example drill play activities that focus on phonological awareness at the preschool level appear in Box 9-3.

Semantics

Many CD programs for working on vocabulary and concepts are commercially available, such as the *Bracken Concept Development Program* (Bracken, 1986), the *Boehm Resource Guide for Basic Concept Teaching* (Boehm, 1989), Levine's (1988) *Great Beginnings for Early Language Learning: Nouns 1, Nouns 2, Concepts, Associations, Prepositions* (Pro-Ed, Inc), and *Vocabulary with EASE* (AGS Publishing, 2005), to name just a few. Most computer software designed for developing vocabulary, such as the *First Words I and II* and *First Verbs*, *Sterling Editions* programs (Wilson & Fox, 1982-2005), *The Deciders Take On Concepts* (Interactive software. Eau Claire, WI: Thinking Publications), *Exploring Early Vocabulary Series* (Burlington, VT: Laureate Learning Systems, Wilson, M., & Fox, B.), *Words and Concepts Series* (Burlington, VT: Laureate Learning Systems), and *Basic Words for*

BOX 9-3 Example Drill Play Phonological Awareness Activities**GO WISH FOR FISH****Awareness Goal:**

Rhyming

Materials:

Pairs of cards with pictures that rhyme (cat/hat, feet/beet, etc.). Shuffle and distribute six cards to each a group of 2 to 6 players. Put the remaining cards in the “fish pond” at the center of the table.

Instructions.

We’re going to play “Go Wish for Fish” with these cards. First, find the cards you have that rhyme with another card in your hand, and put them in a pile on the table. Jessica, you go first. (Require each child to name all his or her cards, and identify the pairs of cards in his or her hand that rhyme. Have him or her check with others in group that each pair rhymes).

Now we’ll take turns asking the person next to you for a card that rhymes with one you have. Jason, tell us the name of one of the cards in your hand that you would like a rhyme for. You could ask Malik if he has a card that rhymes with pig. If he does, he’ll give it to you, you say the two words to be sure they rhyme, and you’ll have another pair for your pile. Malik, if you don’t have one that rhymes with pig, say “Go Wish for Fish” and Jason will pick a new card from the fish pond. (Guide the students to ask for and receive rhyming words for cards in their hand. Require both the asker and receiver to say the names of the two cards to show they rhyme. If the receiver has no rhyming card, have each think of a word that would rhyme with the card named. Continue playing until one child has no cards left.)

WE’VE GOT RHYTHM**Awareness Goal:**

Syllable counting

Materials:

Rhythm band instruments; or “rain sticks” the students make by putting beans or rice inside a paper towel tube and sealing each end with tape.

Instructions.

Have students sit in a circle. Give each a rhythm instrument. Start by going around the circle, asking each child to say his or her name. After he or she does, ask students to listen for how many parts it has. Model shaking a rain stick once for each syllable, invite students to shake their instrument once for each syllable. Continue counting the syllables for the name of each student in the group. Then present other words, such as names of objects in the vicinity. Guide students to count the syllables and shake their instrument once for each syllable. Invite students to volunteer other words for the group to try.

Children CD-ROM: Version 2 (San Luis Obispo, CA: LocuTour Multimedia), use a drill or drill play format. As we’ve said before, many children enjoy pushing the buttons and seeing the pictures and animations on the computer screen, and so computer-assisted intervention is often successful in motivating clients to persist with the drills the software programs contain. Schery and O’Connor (1995) discussed the *Programs for Early Acquisition of Language* (PEAL; Meyers, 1985) and the *ALPHA* programs, both designed to teach basic vocabulary to children with a variety of disabilities at early stages of language development. These programs were both found to have positive effects on word learning but did not show dramatically different results from those seen in more traditional intervention.

Computers may be particularly good contexts for teaching action verbs. Since we know these forms are difficult for children with language disorders (Loeb, Pye, Redmond, & Richardson, 1996), finding effective intervention formats is especially important. Because computer animations can display action more compellingly than a static picture, they may be particularly facilitative for these forms. Still, Schery and O’Connor (1995) emphasize that, while computer-based language programs can offer an additional tool and provide motivating contexts for language activities, they do not appear to be a replacement for an interactive environment with a responsive adult.

Syntax and Morphology

Many CD approaches to teaching syntax and morphology were developed during the 1970s, in the heyday of enthusiasm for behaviorist approaches in our field. Fey (1986) discussed several

available in the research literature. Some CD approaches to syntactic and morphological development also have been made available as commercial packages, such as the *Fokes Sentence Builder* (Fokes, 1976), the *Communication Training Program* (Waryas & Stremel-Campbell, 1983), the *Monterey Language Program* (Gray & Ryan, 1971), *Teach Me Language* (Freeman & Dakes, 1996), and *Verbal Behavior* (Carbone, 2003). An alternative to employing these operant grammar training programs is to follow the suggestions of Fey, Long, and Finestack (2003). They argue that supplementing other, more naturalistic methods with drill and drill-play activities that elicit imitation of target forms makes sense, especially when the elicited imitation activities *contrast* related forms. One such approach from the literature is presented here, both to exemplify what these kinds of programs look like and also because this particular approach has been found to be highly successful in improving grammatical production (Cleave & Fey, 1997). Procedures for using Connell’s (1982) CD procedure for training syntactic rules with the help of contrasts, using the form, “NP is (verb)-ing,” are summarized in Table 9-4.

Again, any CD approach, whether commercially packaged, derived from the literature, or designed by the clinician, can be modified according to Fey’s (1986) guidelines to increase its naturalness. Let’s look at some of the ways in which we might modify Connell’s (1982) approach as an example of how this might be done. Remember that in Chapter 3 we talked about several ways to increase the naturalness of CD activities. These include making the client’s contribution informative, creating intervention contexts in which there is a real motivation to communicate, providing

TABLE 9-4 Training Procedures for Teaching the Syntactic Rule “NP is (verb)-ing” through Contrasts

Target behavior: Spontaneous production of “NP is (verb)-ing” in response to questions.

Materials: 20 pictures of assorted agents doing various actions.

Step	Clinician Stimulus	Client Response	Criterion for Moving to Next Step in Program
1	What is the NP doing? Say, “NP is (verb)-ing.”	NP is (verb)-ing.	90% correct
2	NP is (verb)-ing. Now the NP is done. What did the NP do? (Show picture, then take it away.) Say, “NP (verb)-ed.”	NP (verb)-ed.	90% correct
3	What is the NP doing? (Show picture.)	NP is (verb)-ing.	90% correct
4	NP is (verb)-ing. Now the NP is done. What did the NP do? (Show picture, then take it away.)	NP (verb)-ed.	90% correct
5	What is the NP doing? (Show picture) What did the NP do? (Take it away.)	NP is (verb)-ing and NP (verb)-ed.	90% correct

Generalization training: Repeat Step 5 with different pictures, clinicians, and environments.

Adapted from Connell, P. (1982). On training language rules. *Language, Speech, and Hearing Services in Schools, 13*, 231-248.

distracter items, and presenting stimuli within cohesive texts. Try to think of several ways that Connell’s approach could be modified to achieve these ends. Our suggestions, which are only a sample of the many possible ways this could be done, are listed in [Box 9-4](#).

A variety of computer software also is available for training syntactic and morphological goals using drill and drill play. The vast majority of this software targets receptive performance, however. As we’ve seen, receptive training is probably not necessary for most clients and does not necessarily generalize to use of the same forms in production. Production skills, on the other hand, do tend to generalize more readily to comprehension. For these reasons we would not put a great deal of time or money into the use of syntactic intervention programs that focus exclusively on receptive language. If such programs are available and clients like to use the computer, they might be used as follow-up to production training, as extra practice, and to ensure that production targets have generalized to reception. Schery and O’Connor (1997), for example, showed that special needs preschoolers who received an additional hour per week of computer training for 10 weeks, over and above what they received during normal classroom instruction, showed greater gains than peers who did not receive the extra training. Computerized language instruction, then, can be a helpful adjunct

to more traditional intervention. And Owens (2009) suggests that computer-assisted training works best when the child and the clinician participate together in the program. Especially at the DL level, sitting children alone in front of a computer screen may not be best practice.

Child-Centered Approaches to Intervention for the Child with Developing Language

We talked earlier about child-centered (CC) intervention methods and discussed their use with children in the emerging language phase, when no specific targets of intervention are identified and the goal is simply improved communication. Let’s look at how some of these methods can be used for children in the DL phase.

Indirect Language Stimulation

The major characteristics of indirect language stimulation (ILS), as defined by Junker and Stockman (2002), include the following:

- Contingent feedback (saying something that relates to what the child said/did; e.g., child picks up toy car; Clinician remarks, “Oh, nice car! You have the car!”).
- Balanced turn-taking (letting the child lead and then responding, rather than using extensive questions and initiations to get the child to talk; e.g., child is playing silently, clinician plays

BOX 9-4 Naturalistic Modifications of Connell’s (1982) CD Procedure

1. Use a cohesive text. Instead of a series of unrelated pictures, use a picture book or set of sequence pictures that depicts a series of related actions, such as those involved in dressing or in preparing food. Go through all the steps in Connell’s procedure in exactly the same way, using these pictures that form a cohesive unit as the stimuli.
2. Make the contribution informative. Using either unrelated picture cards or pictures that form a cohesive unit as suggested in 1, sit with the client and the pictures at a table. Place a favorite doll, action figure, or photo of someone the client knows across the table from the two of you, with its back toward you so it cannot “see” the pictures. Tell the client the doll wants to know what’s going on in the pictures, so the client must “tell” the doll what’s going on by answering your questions. Both to increase the communicative aspect of the activity and to provide distracter items, occasionally have the doll respond to the client’s utterance by talking for it in a funny voice. Express surprise or interest in what the client is saying, and make a comment not directly related to the picture descriptions. Then tell the client the doll is so interested it wants to know more, and resume the activity.
3. Increase motivation to communicate. Use a cohesive set of pictures, and audio record each of the client’s responses to the imitative set of items in Step 1 of Connell’s procedure (see Table 9-4). Tell the client he or she can take the audio home and play the “story” for his or her parents, so the parents can hear how well the child tells the story. Do the same for Step 3 of Connell’s procedure (see Table 9-4).

silently alongside, when child turns toward clinician, she remarks: “Oh, I see what you have! You have the blue car; I have the red one!”).

- Extension of the child’s topic (saying something that gives more information about what the child just said/did; e.g., child holds up car for clinician to see, clinician remarks, “You have the blue car! That’s neat! Your blue car has big, black wheels!”).

ILS can take place in a variety of contexts, including play with toys or role-plays, during outdoor play, shared book reading, cooking, crafts, or other common preschool activities. In Chapter 3, we suggested that ILS in its pure form, when no specific goals are identified, is most appropriate for children with mean lengths of utterance (MLUs) less than 3.0, when first sentences are emerging. A modified form of ILS might be used at later stages, if we incorporate some specific goals and use it as a way to provide multiple meaningful models of target forms. Instead of using primarily self-talk and parallel talk in an unstructured play setting, we can provide a more contrived play setting, one in which materials have been selected for the child, activities are suggested by the clinician, and play behaviors are modeled to make it highly probable that the need for target forms and meanings will arise. For example, suppose we are working on the use of irregular past-tense verb forms and want to provide some ILS as an introduction to these forms, to allow the client to see how they are used. We might give the child a set of toys such as a dollhouse, garage, or play house with matching people and accoutrements. As the child manipulates the toys, we might narrate, “Oh, he *went* in the house. Uh-huh. Then he *found* a little dog. How nice. Then he *said* ‘hi’ to it. The dog *came* closer to him, didn’t he? Then he *saw* a doghouse.” We also might model talking for one of the toys—the dog, for example: “Arf, arf, I *found* a bone. I *saw* it in the yard.” Although an opportunity to model irregular past-tense forms might not arise in every remark the clinician makes, each opportunity for providing these models could be capitalized on. If the child began to model the clinician’s narration and role-taking, using some irregular past forms correctly or incorrectly, the expansion, extension, recast, and buildup and breakdown forms of ILS feedback could be provided. Camarata and Nelson (2006), Hancock and Kaiser (2006), and Leonard and Fey (1991) provided additional detailed examples of using modified ILS techniques to elicit grammatical forms in the DL phase. Shriberg and Kwiatkowski (1982a) also discussed this approach as a means of facilitating phonological development.

Fey (2000) advocated using recast sentences as a particularly effective form of ILS for children in the DL period. Taking a client’s utterance and immediately recasting it in a different syntactic form that retains the child’s meaning is thought to provide a particularly useful kind of feedback. Recasting is thought to help children see how language rules work to provide several different ways of expressing similar semantic relations. For example, if a child remarks, “Big doggy mad,” the clinician might recast, “He is? Is the big doggy mad?” Research on children with a variety of disabilities has demonstrated positive effects of this kind of recasting on language growth (Nelson, Camarata, Welsh, Butkovsky, & Camarata, 1996; Yoder, Davies, Bishop, & Munson, 1994). Nelson et al. found that recast treatment was superior to a clinician-directed imitative approach. Leonard et al. (2008) showed that recasting that focused on specific forms was more effective than a general ILS approach. Fey and Loeb (2002), however, suggest that these techniques work best when children are producing a few of the target forms in their own speech, so careful analysis of the child’s current productions is important when choosing targets for recasts.

Some additional techniques for eliciting a variety of language forms within the modified ILS approach are suggested by Fey et al. (2003) and Owens (2009). Examples are given in Table 9-5.

ILS can also be taught to parents, daycare providers, and other caregivers, as a way to expand the child’s opportunities for language stimulation. Law, Garrett, and Nye (2004) concluded in their literature review of intervention programs for preschoolers that intervention that was administered by trained parents was, in general, as effective as intervention that was administered by SLPs. Kohnert et al. (2005) identified several components shared by successful parent training programs:

- Focus on specific language facilitation strategies (e.g., modeling, expansion, recasts, imitation, responsive feedback).
- Using multiple instructional methods (e.g., demonstration, coaching, role plays, mediated parent-child interactions, video recorded examples, written materials, and specific instructive feedback).
- Teaching a progression of skills and strategies embedded in specific activities.

Girolametto, Weitzman, and Greenberg (2003) also showed that day care providers could be trained to provide ILS to children in small groups. The training was aimed at helping the workers be more responsive to children’s initiations, engage children in interactions, model simplified language, and encourage peer interactions. Their study showed that trained caregivers were superior to untrained staff in waiting for children to initiate, engaging them in turn-taking, using face to face interaction, and including uninvolved children. The children assigned to trained caregivers talked more, produced more word combinations, and talked to peers more often than the children in control groups. Further research by this group (DeRivera, Girolametto, Greenberg, & Weitzman, 2005) suggests that the use of questions in interactions is another important target of in-service training. Open-ended questions, those that continue the child’s topic, and questions followed by a pause to allow the child’s response were found to result in increases in the complexity of preschool children’s responses. These strategies, too, would be helpful skills for training parents and caregivers in ILS. Pence, Justice, & Wiggins (2008), though, suggested that preschool teachers will need ongoing support from SLPs in this endeavor.

Facilitated Play

An added advantage in using modified ILS in this way with children in the DL period is that, in addition to providing language models, we can provide models of more elaborated forms of play. As we discussed earlier, play skills often lag behind in children with language disorders, and a modified ILS approach gives us the opportunity to model forms of play appropriate for this developmental period, such as role-playing and using objects symbolically. Culatta (1994) discussed the advantages of play as a format for language intervention. She argued that play is an especially appropriate context for language learning because it is highly motivating; it permits the integration of content, form, and function; and it encourages the child to bring knowledge of “scripts” for everyday events to the foreground where this knowledge can support language use. In turn, play provides opportunities for elaborating existing scripts through enacting a wider set of roles and possibilities than are present in “reality.” In a doctor play scene, for example, the child can be the patient but also can play the doctor, getting a chance to use language appropriate to that role. Culatta suggested using child-centered play contexts, not only for indirect language

TABLE 9-5 Language Elicitation Techniques

Technique	Target	Example
Violate routines	Protest, request, negative sentence	During snack, neglect to give client a cup and begin to pour juice.
Violate expectations	Comment, protest, negative sentence	Clinician: "Here's your sandwich." Child: "Nothing in it." Clinician: "Oh? What should I do?"
Withhold objects or turns	Protest, request, negative sentence	Give each other child a turn to operate a toy and skip client when moving to next child.
Misuse objects	Comment, verbs	Use a hairbrush to "brush teeth."
Misname objects	Comment, negative sentence, labels	Clinician: "How do you like my new hat?" (while pointing to shoes)
Misplace objects	Comment, negative sentence, spatial terms	Put paper plate on head.
Provide inappropriate objects for activity	Comment, labels, negatives, word combinations	Provide noodles and cheese when activity is making a sandwich.
"Pass it on"	Request for information	Clinician: "Do you know where the juice is?" Child: "No." Clinician: "Go see if Jamie does." Child: "Do you know where the juice is?"
"Strong, silent type"	Request for information	Clinician (placing interesting object before client): "This is neat." Child: "What is it?" Clinician: "A barometer." (Say nothing else until child asks for more information).
"Guess what"	Request for information, past tense	Clinician: "Guess what I did yesterday?"
Expansion invitation	Infinitive	Child: "I want crayon." Clinician: "You want a crayon to eat?" Client: "No, to color with." Clinician: "What?" Client: "I want a crayon to color with."

Ten principles of grammar facilitation for children with specific language impairments. *American Journal of Speech-Language Pathology*, 12, 3-15; Owens, R. (2009). *Language disorders: A functional approach to assessment and intervention* (5th ed.). Boston, MA: Allyn & Bacon.

stimulation, but also to develop a variety of language skills, such as the following:

- *Enhancing narrative ability* by engaging the child in direct metalinguistic planning of the roles, plans, attempts, and outcomes to be acted out in the play.
- *Facilitating turn-taking* by contriving reasons to communicate within the play. The clinician can require the child to communicate to multiple characters. If birthday party play is going on, the clinician can have the client tell each stuffed animal "guest" what to bring to the party.
- *Increasing opportunities for decontextualized language.* The clinician can use increasingly abstract props in the play, starting with real objects and moving to replicas, constructions, toys, and finally to imaginary props. The clinician also can include some discussion of events remote in space and time within the context of the play.
- *Enhancing the expression of communicative intentions.* The clinician can structure opportunities within the play for the child to negotiate roles and plans; project events; state rules and goals; and express the feelings, intentions, and desires of characters. The clinician can begin by modeling these functions and move to asking the child to express the functions following the model.
- *Increasing vocabulary.* Words specific to particular scripts can be used by the clinician multiple times within a play episode. If a shopping script is being used, the words *cashier*, *customer*, *groceries*, and *cart* might be used. Generic words important for play negotiation and enactment also can be modeled, such as *cooperate*, *prepare*, and *character*.

- *Developing emergent literacy.* Play provides many opportunities for children to pretend to write and read and to see why written forms are used. The clinician can encourage clients to make real or pretend lists, signs, and labels and to write or pretend to write notes and instructions to other characters within the play.

Patterson and Westby (1998) provided some guidelines for the kinds of play to model for children in the DL phase. These are summarized in Table 9-6. Culatta (1994) gave an extensive list of themes and events that can be used as a basis for play scenes for children with DL. Examples are given in Table 9-7.

Hybrid Approaches to Intervention for the Child with Developing Language

Hybrid methods of intervention supply a valuable middle ground for planning language programs. More naturalistic and child-centered than CD approaches, but more structured, sequenced, and clinician-controlled than ILS or facilitated play, these techniques provide a range of alternatives for clinicians to use in improving communicative function. We talked in Chapter 3 about several hybrid techniques. Some that were discussed in detail, including *incidental* and *milieu* teaching, are extremely well suited to addressing semantic and syntactic goals of the DL period. Focused stimulation and script therapy, also outlined in Chapter 3, are likewise very useful during this phase. Let's look at some forms of focused stimulation and some extensions of the script therapy approach, as well as a few other hybrid methods that can be added to the ones we've already discussed.

TABLE 9-6 Guidelines for Modeling Pretend Play

Developmental Level	Props to Use in Play	Event Description Types to Use in Play	Roles to Take and Give to Toys and Others
3–3½ yr	Replica toys (dollhouse, barn, etc.); use objects to represent others (block for phone); use blocks as enclosures; use sandbox, water table for imaginative play.	Salient, memorable events in which the child has taken part (e.g., visit to doctor, losing a favorite toy).	Use doll as participant in play; talk for doll; play parent to doll.
3½–4 yr	Use language to set scene and invent some props; build city with blocks.	Familiar, observed events in which the child has not taken part (e.g., firehouse, police car, superhero from TV show).	Use dolls to act out scenes; take multiple roles in play.
4–5 yr	Use language exclusively to set action and roles.	Novel events and imaginative activities that child has not participated in or observed (e.g., pretend to be cowpunchers on the range; ride horses, set up camp, cook meal, sing around the campfire).	Use language to take roles, using different voices, etc.

TABLE 9-7 Themes and Events to Use as Play Contexts in Language Intervention

Script	Events	Potential Problems
Getting ready for school	Get dressed, brush teeth, pack lunch, do chores, eat breakfast, get on bus.	Can't wake children, burn toast, can't find lunch box, child is sick, out of milk, miss bus.
Going on a trip	Plan and pack, load car, leave, drive to destination, arrive at hotel, go to pool.	Child doesn't want to go, no room for favorite blanket, car out of gas, child is carsick, no rooms, forgot swimsuit.
Taking care of sick baby	Take temperature, rock baby, call doctor, take in car to doctor, doctor gives baby medicine, take baby home, give juice, put to bed.	Baby still cries, line is busy, car won't start, baby throws up medicine, baby spills juice.

Adapted from Culatta, B. (1994). Representational play and story enactments: Formats for language intervention. In J. Duchan, L. Hewitt, & R. Sonnenmeier (Eds.), *Pragmatics: From theory to practice* (pp. 105-119). Englewood Cliffs, NJ: Prentice-Hall.

Hybrid Approaches in Phonology

Prezas and Hodson (2010) provided a description of a hybrid approach to intervention with unintelligible children. Their approach uses detailed assessment of phonological production to target sounds and processes. It is based on the principles of (1) the need to develop strong auditory models for target sounds, (2) developing kinesthetic patterns to match these auditory images, (3) the use of a phonetic environment to facilitate correct sound production, and (4) the child's active involvement in phonological acquisition. A cycling method of goal attack is used. Each intervention session has several components, including the following:

- Reviewing the targets from the previous session.
- Providing auditory bombardment for target sounds using amplification, such as an auditory training unit.
- Practicing production of a small number of words containing target sounds or syllable shapes in drill play activities.
- Identifying new words for the next session's or cycle's production practice by identifying two to five target words in which the child can pronounce the target sound or syllable shape correctly.
- Repeating the auditory bombardment segment.
- Giving parents the list of words for auditory bombardment to read to the child at home between sessions.

Notice that this approach is considered hybrid even though it contains a drill play phase during the production practice segment. Hybrid programs such as this one can take advantage of several approaches and even include some CD activities within their overall plan.

Focused Stimulation

Weismer and Robertson (2006) presented a detailed description of a program designed to facilitate grammar acquisition in language-impaired preschoolers. They refer to this program as a "focused stimulation" approach, because it focuses on specific forms and uses multiple models with a variety of forms of clinician feedback to stimulate language goals. The overall program maintains a hybrid orientation with the context of natural conversation between a client and an adult. Targets for the intervention are selected from language sample data, but Weismer and Robertson emphasize that focused stimulation can be used for a variety of targets including syntax, morphology, vocabulary, pragmatics, and phonology. Forms that the client used less than half the time correctly in obligatory contexts are considered high-priority target forms. Table 9-8 summarizes some of the techniques used in this approach. Lederer (2001) showed that focused stimulation was effective for increasing vocabulary in preschool children.

TABLE 9-8 Focused Stimulation Procedures

Targets	Explanation	Example
Demonstrating use of targets	Targets are moved to sentence initial or final position, where they are most salient.	Child: I need a red block. Adult: <i>Will</i> you get it? Child: OK Adult: You <i>will</i> ? Good, then I <i>will</i> get a blue one.
Expansion	Errors in the child's utterance are corrected.	Child: Her my dolly. Adult: Yes, <i>she</i> is yours.
Recast	Keeps child's meaning but changes the form of the sentence.	Child: This easy! Adult: <i>Is</i> it? <i>Is</i> it easy for you? It <i>isn't</i> easy for me!
Buildups and break-downs	Demonstrate how to manipulate the elements in a sentence.	Child: I make a mess! Adult: You did! You made a big mess! A big mess! You certainly did make a mess. You made a mess, all right. Didn't you?
False assertions	Clinician makes a false remark as a prompt for the client to deny it.	Adult: This piece fits here. Child: No it not. Adult: Yes it <i>does</i> . Child: No! Adult: I guess you're right. It <i>doesn't</i> fit here.
Feigned misunderstandings	Clinician pretends not to get the message sent by client.	Child: Me need that. Adult: <i>He</i> needs it? Child: No, me need it. Adult: No, <i>I</i> do (pointing to self).
Forced choices	Provide a model of correct use of the target.	Adult: Do you want some snack? You can say "yes, please," or "no, thank you."
Other contingent queries	Used to encourage client to provide missing information.	Child: I want that one. Adult: What will you do with it? Child: Color. Adult: Oh, you want the red crayon so you can color with it.
