Chapter 2 Application Layer

KUROSE ROSS

A note on the use of these ppt slides:

We're making these slides freely available to all (faculty, students, readers). They're in PowerPoint form so you see the animations; and can add, modify, and delete slides (including this one) and slide content to suit your needs. They obviously represent a *lot* of work on our part. In return for use, we only ask the following:

- If you use these slides (e.g., in a class) that you mention their source (after all, we'd like people to use our book!)
- If you post any slides on a www site, that you note that they are adapted from (or perhaps identical to) our slides, and note our copyright of this material.

Thanks and enjoy! JFK/KWR

Chapter 2: outline

- 2.1 principles of network applications
- 2.2 Web and HTTP
- 2.3 FTP
- 2.4 electronic mail
 - SMTP, POP3, IMAP
- 2.5 DNS

Chapter 2: application layer

our goals:

- conceptual, implementation aspects of network application protocols
 - transport-layer service models
 - client-server paradigm
 - peer-to-peer paradigm

- learn about protocols by examining popular application-level protocols
 - HTTP
 - FTP
 - SMTP / POP3 / IMAP
 - DNS

Some network apps

- e-mail
- web
- text messaging
- remote login
- P2P file sharing
- multi-user network games
- streaming stored video (YouTube, Hulu, Netflix)

- voice over IP (e.g., Skype)
- real-time video conferencing
- social networking
- search
- ***** ...
- ***** ...

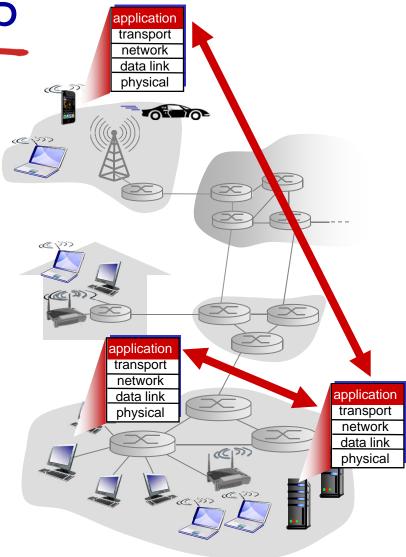

Creating a network app

write programs that:

- run on (different) end systems
- communicate over network
- e.g., web server software communicates with browser software

no need to write software for network-core devices

- network-core devices do not run user applications
- applications on end systems allows for rapid app development, propagation

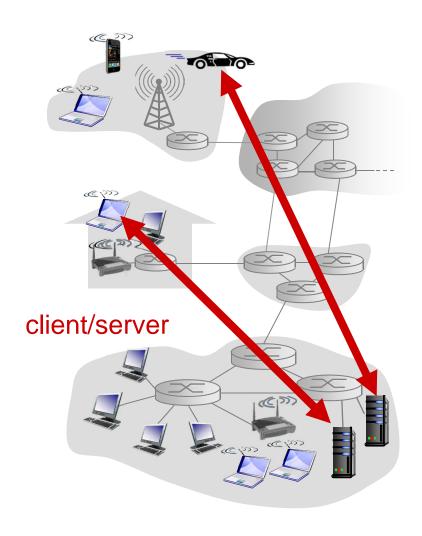

Application architectures

possible structure of applications:

- client-server
- peer-to-peer (P2P)

Client-server architecture

server:

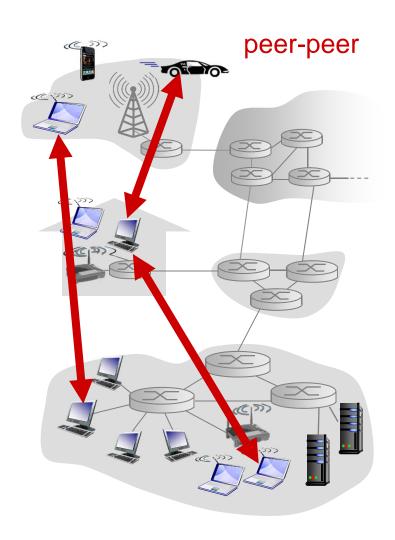

- always-on host
- permanent IP address
- data centers for scaling

clients:

- communicate with server
- may be intermittently connected
- may have dynamic IP addresses
- do not communicate directly with each other

P2P architecture

- no always-on server
- arbitrary end systems directly communicate
- peers request service from other peers, provide service in return to other peers
 - self scalability new peers bring new service capacity, as well as new service demands
- peers are intermittently connected and change IP addresses
 - complex management

Processes communicating

process: program running within a host

- within same host, two processes communicate using inter-process communication (defined by OS)
- processes in different hosts communicate by exchanging messages

clients, servers

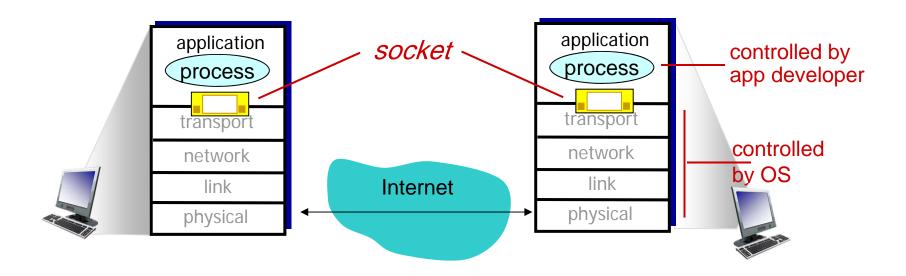

client process: process that initiates communication server process: process that

waits to be contacted

 aside: applications with P2P architectures have client processes & server processes

Sockets

- process sends/receives messages to/from its socket
- socket analogous to door
 - sending process shoves message out door
 - sending process relies on transport infrastructure on other side of door to deliver message to socket at receiving process

Addressing processes

- to receive messages, process must have identifier
- host device has unique 32bit IP address
- Q: does IP address of host on which process runs suffice for identifying the process?
 - A: no, many processes can be running on same host

- identifier includes both IP address and port numbers associated with process on host.
- example port numbers:
 - HTTP server: 80
 - mail server: 25
- to send HTTP message to gaia.cs.umass.edu web server:
 - IP address: 128.119.245.12
 - port number: 80
- more shortly...

App-layer protocol defines

- types of messages exchanged,
 - e.g., request, response
- message syntax:
 - what fields in messages & how fields are delineated
- message semantics
 - meaning of information in fields
- rules for when and how processes send & respond to messages

open protocols:

- defined in RFCs
- allows for interoperability
- e.g., HTTP, SMTP
- proprietary protocols:
- e.g., Skype

What transport service does an app need?

data integrity

- some apps (e.g., file transfer, web transactions) require
 100% reliable data transfer
- other apps (e.g., audio) can tolerate some loss

timing

some apps (e.g., Internet telephony, interactive games) require low delay to be "effective"

throughput

- some apps (e.g., multimedia) require minimum amount of throughput to be "effective"
- other apps ("elastic apps")
 make use of whatever
 throughput they get

security

encryption, data integrity,

• • •

Transport service requirements: common apps

_	application	data loss	throughput	time sensitive
				_
$ar{W}$	file transfer	no loss	elastic	no
	e-mail	no loss	elastic	no
	leb documents	no loss	elastic	no
real-tir	me audio/video	loss-tolerant	audio: 5kbps-1Mbps	yes, 100's
_			video:10kbps-5Mbps	msec
stor	ed audio/video	loss-tolerant	same as above	yes, few secs
inte	eractive games	loss-tolerant	few kbps up	yes, 100's msec
ī	text messaging	no loss	elastic	yes and no

Internet transport protocols services

TCP service:

- reliable transport between sending and receiving process
- flow control: sender won't overwhelm receiver
- congestion control: throttle sender when network overloaded
- does not provide: timing, minimum throughput guarantee, security
- connection-oriented: setup required between client and server processes

UDP service:

- unreliable data transfer between sending and receiving process
- does not provide: reliability, flow control, congestion control, timing, throughput guarantee, security, orconnection setup,

Q: why bother? Why is there a UDP?

Internet apps: application, transport protocols

application	on	application layer protocol	underlying transport protocol
			_
e-m	ail	SMTP [RFC 2821]	TCP
remote terminal acce	SS	Telnet [RFC 854]	TCP
We	b	HTTP [RFC 2616]	TCP
file transf	er	FTP [RFC 959]	TCP
streaming multimed	lia	HTTP (e.g., YouTube),	TCP or UDP
		RTP [RFC 1889]	
Internet telepho	∩y	SIP, RTP, proprietary	
	-	(e.g., Skype)	TCP or UDP

Securing TCP

TCP & UDP

- no encryption
- cleartext passwds sent into socket traverse Internet in cleartext

SSL

- provides encrypted TCP connection
- data integrity
- end-point authentication

SSL is at app layer

 Apps use SSL libraries, which "talk" to TCP

SSL socket API

- cleartext passwds sent into socket traverse Internet encrypted
- See Chapter 7

Chapter 2: outline

- 2.1 principles of network applications
 - app architectures
 - app requirements
- 2.2 Web and HTTP
- 2.3 FTP
- 2.4 electronic mail
 - SMTP, POP3, IMAP
- 2.5 **DNS**

Web and HTTP

First, a review...

- web page consists of objects
- object can be HTML file, JPEG image, Java applet, audio file,...
- web page consists of base HTML-file which includes several referenced objects
- each object is addressable by a URL, e.g.,

www.someschool.edu/someDept/pic.gif

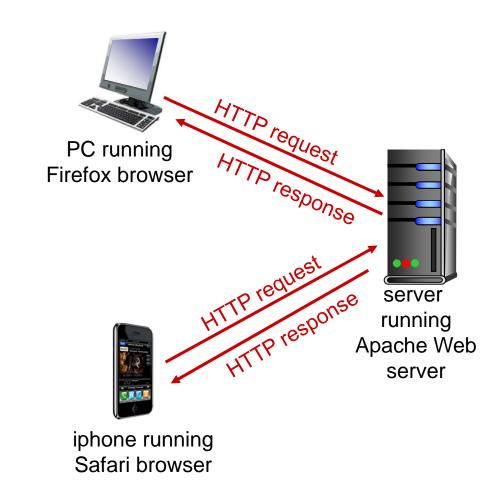

host name

path name

HTTP overview

HTTP: hypertext transfer protocol

- Web's application layer protocol
- client/server model
 - client: browser that requests, receives, (using HTTP protocol) and "displays" Web objects
 - server: Web server sends (using HTTP protocol) objects in response to requests

HTTP overview (continued)

uses TCP:

- client initiates TCP connection (creates socket) to server, port 80
- server accepts TCP connection from client
- HTTP messages

 (application-layer protocol messages) exchanged between browser (HTTP client) and Web server (HTTP server)
- TCP connection closed

HTTP is "stateless"

 server maintains no information about past client requests

aside

protocols that maintain "state" are complex!

- past history (state) must be maintained
- if server/client crashes, their views of "state" may be inconsistent, must be reconciled
- e.g.TCP,

HTTP overview (continued)

- A stateful protocol is a protocol in which part of the data that is exchanged between the client and the server systems includes state information. Both systems track of the state of the communication session.
- A stateless protocol is a protocol in which neither the client nor the server system has an obligation to keep track of the state of the communication session. A stateless protocol does not support most reliability features; and data that were sent can be lost or delivered out-of-sequence. The main advantages is lower overhead and a degree of isolation between the client and the server. Connectionless protocols are typically stateless.

HTTP connections

non-persistent HTTP

- at most one object sent over TCP connection
 - connection then closed
- downloading multiple objects required multiple connections

persistent HTTP

 multiple objects can be sent over single TCP connection between client, server

Non-persistent HTTP

suppose user enters URL:

www.someSchool.edu/someDepartment/home.index

(contains text, references to 10 jpeg images)

- Ia. HTTP client initiates TCP connection to HTTP server (process) at www.someSchool.edu on port 80
- 2. HTTP client sends HTTP request message (containing URL) into TCP connection socket.

 Message indicates that client wants object someDepartment/home.index
- Ib. HTTP server at host
 www.someSchool.edu waiting
 for TCP connection at port 80.
 "accepts" connection, notifying client
- 3. HTTP server receives request message, forms response message containing requested object, and sends message into its socket

Non-persistent HTTP (cont.)

5. HTTP client receives response message containing html file, displays html. Parsing html file, finds 10 referenced jpeg objects

4. HTTP server closes TCP connection.

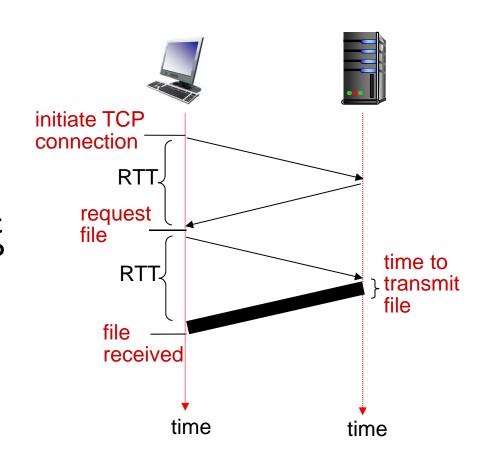

6. Steps 1-4 repeated for each of 10 jpeg objects

Non-persistent HTTP: response time

RTT (definition): time for a small packet to travel from client to server and back

HTTP response time:

- one RTT to initiate TCP connection
- one RTT for HTTP request and first few bytes of HTTP response to return
- file transmission time
- non-persistent HTTP
 response time =
 2RTT+ file transmission
 time

Persistent HTTP

non-persistent HTTP issues:

- requires 2 RTTs per object
- OS overhead for each TCP connection
- browsers often open parallel TCP connections to fetch referenced objects

persistent HTTP:

- server leaves connection open after sending response
- subsequent HTTP
 messages between same
 client/server sent over
 open connection
- client sends requests as soon as it encounters a referenced object
- as little as one RTT for all the referenced objects

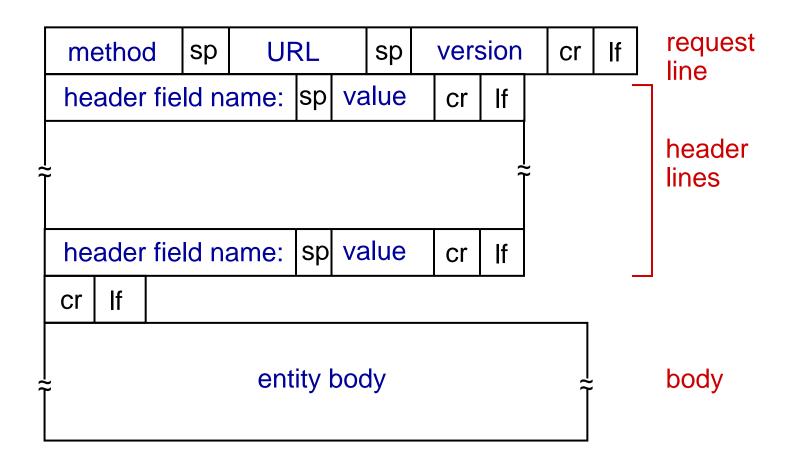

HTTP request message

- two types of HTTP messages: request, response
- HTTP request message:
 - ASCII (human-readable format)

```
line-feed character
request line
(GET, POST,
                    GET /index.html HTTP/1.1\r\n
                    Host: www-net.cs.umass.edu\r\n
HEAD commands)
                    User-Agent: Firefox/3.6.10\r\n
                    Accept: text/html,application/xhtml+xml\r\n
            header
                    Accept-Language: en-us,en;q=0.5\r\n
              lines
                    Accept-Encoding: gzip,deflate\r\n
                    Accept-Charset: ISO-8859-1,utf-8;q=0.7\r\n
                    Keep-Alive: 115\r\n
carriage return,
                    Connection: keep-alive\r\n
line feed at start
                     r\n
of line indicates
end of header lines
```

carriage return character

HTTP request message: general format

Uploading form input

POST method:

- web page often includes form input
- input is uploaded to server in entity body

URL method:

- uses GET method
- input is uploaded in URL field of request line:

www.somesite.com/animalsearch?monkeys&banana

Method types

HTTP/I.0:

- GET
- POST
- * HEAD
 - asks server to leave requested object out of response

HTTP/I.I:

- GET, POST, HEAD
- PUT
 - uploads file in entity body to path specified in URL field
- DELETE
 - deletes file specified in the URL field

HTTP response message

```
status line
(protocol
status code
                HTTP/1.1 200 OK\r\n
                Date: Sun, 26 Sep 2010 20:09:20 GMT\r\n
status phrase)
                Server: Apache/2.0.52 (CentOS)\r\n
                Last-Modified: Tue, 30 Oct 2007 17:00:02
                  GMT\r\n
                ETag: "17dc6-a5c-bf716880"\r\n
     header
                Accept-Ranges: bytes\r\n
       lines
                Content-Length: 2652\r\n
                Keep-Alive: timeout=10, max=100\r\n
                Connection: Keep-Alive\r\n
                Content-Type: text/html; charset=ISO-8859-
                  1\r\n
                r\n
               data data data data ...
 data, e.g.,
 requested
 HTML file
```

HTTP response status codes

- status code appears in 1st line in server-toclient response message.
- some sample codes:

200 OK

request succeeded, requested object later in this msg

301 Moved Permanently

 requested object moved, new location specified later in this msg (Location:)

400 Bad Request

request msg not understood by server

404 Not Found

requested document not found on this server

505 HTTP Version Not Supported

Trying out HTTP (client side) for yourself

I. Telnet to your favorite Web server:

telnet cis.poly.edu 80

opens TCP connection to port 80 (default HTTP server port) at cis.poly.edu. anything typed in sent to port 80 at cis.poly.edu

2. type in a GET HTTP request:

GET /~ross/ HTTP/1.1
Host: cis.poly.edu

by typing this in (hit carriage return twice), you send this minimal (but complete)
GET request to HTTP server

3. look at response message sent by HTTP server!

(or use Wireshark to look at captured HTTP request/response)

User-server state: cookies

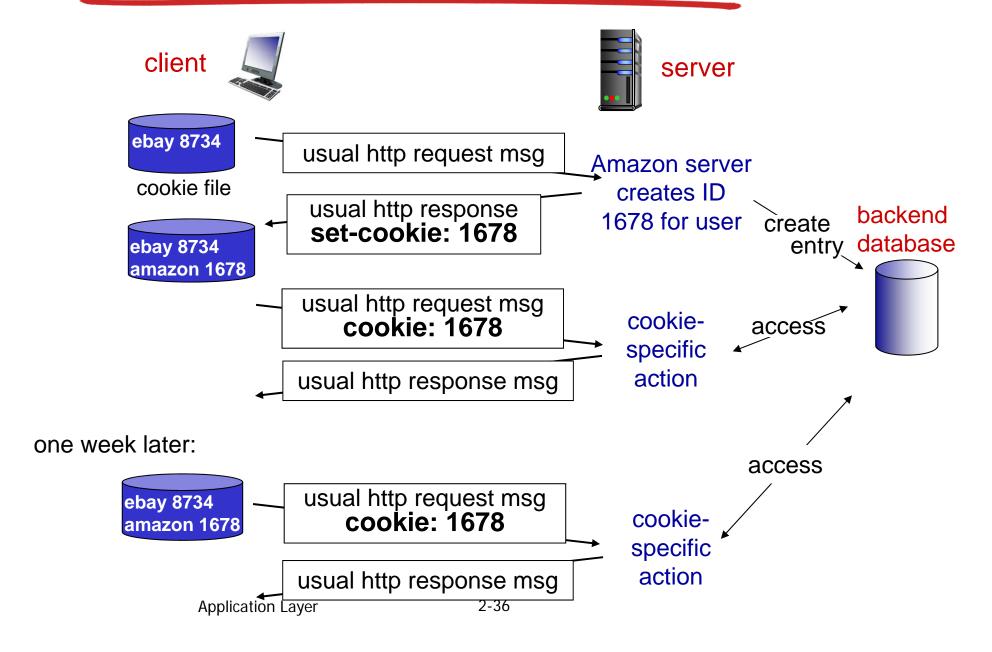

many Web sites use cookies four components:

- I) cookie header line of HTTP response message
- 2) cookie header line in next HTTP request message
- cookie file kept on user's host, managed by user's browser
- 4) back-end database at Web site

example:

- Susan always access Internet from PC
- visits specific e-commerce site for first time
- when initial HTTP requests arrives at site, site creates:
 - unique ID
 - entry in backend database for ID

Cookies: keeping "state" (cont.)

Cookies (continued)

what cookies can be used for:

- authorization
- shopping carts
- recommendations
- user session state (Web e-mail)

cookies and privacy:

- cookies permit sites to learn a lot about you
- you may supply name and e-mail to sites

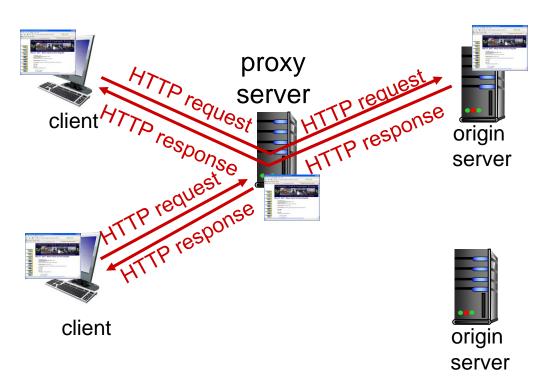

how to keep "state":

- protocol endpoints: maintain state at sender/receiver over multiple transactions
- cookies: http messages carry state

Web caches (proxy server)

goal: satisfy client request without involving origin server

- user sets browser: Web accesses via cache
- browser sends all HTTP requests to cache
 - object in cache: cache returns object
 - else cache requests object from origin server, then returns object to client

More about Web caching

- cache acts as both client and server
 - server for original requesting client
 - client to origin server
- typically cache is installed by ISP (university, company, residential ISP)

why Web caching?

- reduce response time for client request
- reduce traffic on an institution's access link
- Internet dense with caches: enables "poor" content providers to effectively deliver content

Caching example:

assumptions:

- avg object size: I Mbits
- avg request rate from browsers to origin servers: 15 request/sec
- RTT from institutional router to any origin server: 2 sec
- access link rate: 15 Mbps

consequences:

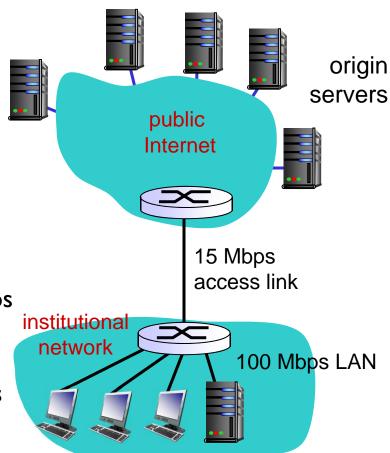

LAN utilization:

(15 request/s) × (1Mbits/request) /100Mbps = 0.15

access link utilization:

(15 request/s) × (IMbits/request)/15Mbps = | problem!

- total delay = Internet delay + access delay + LAN delay
 - = 2 sec + minutes + msecs

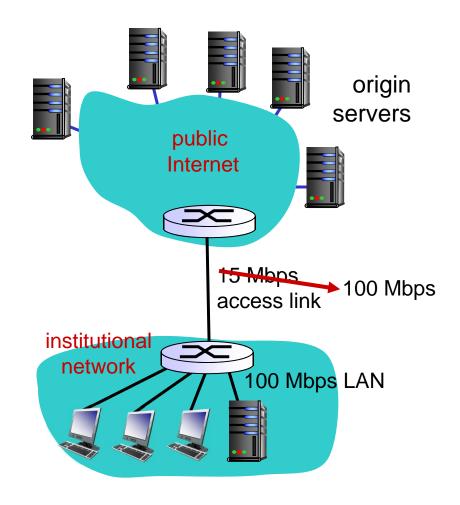

Caching example: fatter access link

assumptions:

- avg object size: I Mbits
- avg request rate from browsers to origin servers: 15 request/sec
- * RTT from institutional router to any origin server: 2 sec
- access link rate: 15 Mbps 100 Mbps

consequences:

- LAN utilization: 0.15
- access link utilization = $\frac{1}{100}$ 0.15
- total delay = Internet delay + access delay + LAN delay
 - = 2 sec + minutes + msecs msecs
 - $= 2 \sec + 10 \text{ms} + 10 \text{ms} = (2.02 \sec)$

Cost: increased access link speed (not cheap!)

Caching example: install local cache

assumptions:

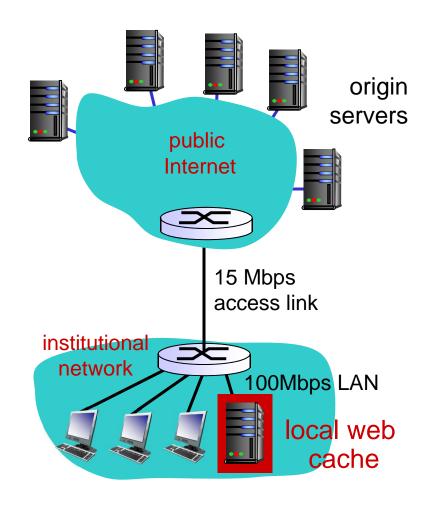

- avg object size: I Mbits
- avg request rate from browsers to origin servers: I 5 request/sec
- RTT from institutional router to any origin server: 2 sec
- access link rate: 15 Mbps

consequences:

- LAN utilization: 0.15
- access link utilization = |
- total delay = Internet (?)
 delay + LAN d ;

How to compute link utilization, delay?

Cost: web cache (cheap!)

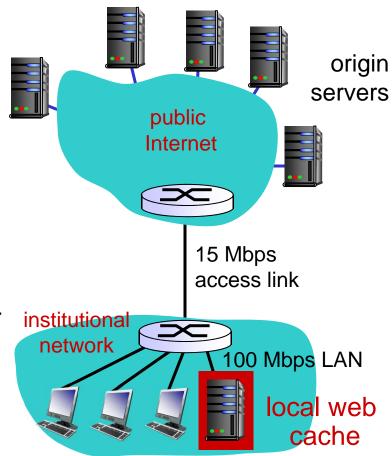

Caching example: install local cache

Calculating access link utilization, delay with cache:

- * suppose cache hit rate is 0.4
 - 40% requests satisfied at cache,
 60% requests satisfied at origin
- * access link utilization:
 - 60% of requests use access link
- total delay
 - = 0.6 * (delay from origin servers) + 0.4
 * (delay when satisfied at cache)
 - = 0.6 (2.01) + 0.4 (0.01 secs)
 - $= \sim 1.21 \text{ secs}$
 - less than with 100 Mbps link (and cheaper too!)

2.02= Internet delay + LAN delay

Hit rates—the fraction of requests that are satisfied by a cache—typically range from 0.2 to 0.7 in practice.

Conditional GET

- Goal: don't send object if cache has up-to-date cached version
 - no object transmission delay
 - lower link utilization
- cache: specify date of cached copy in HTTP request

If-modified-since:
 <date>

 server: response contains no object if cached copy is up-to-date:

HTTP/1.0 304 Not Modified

HTTP request msg object If-modified-since: <date> not modified HTTP response before HTTP/1.0 <date> 304 Not Modified HTTP request msg object If-modified-since: <date> modified after HTTP response <date> HTTP/1.0 200 OK <data>

server

Application Layer

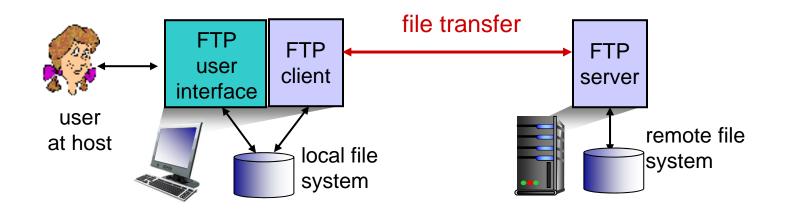

Client

(cache)

Chapter 2: outline

- 2.1 principles of network applications
 - app architectures
 - app requirements
- 2.2 Web and HTTP
- 2.3 FTP
- 2.4 electronic mail
 - SMTP, POP3, IMAP
- 2.5 DNS

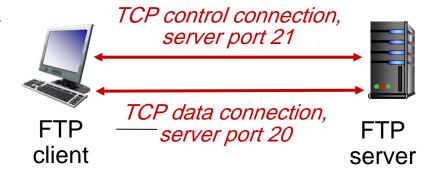

FTP: the file transfer protocol

- transfer file to/from remote host
- client/server model
 - client: side that initiates transfer (either to/from remote)
 - server: remote host
- ❖ FTP: RFC 959
- FTP server: port 21

FTP: separate control, data connections

- FTP client contacts FTP server at port 21, using TCP
- client authorized over control connection
- client browses remote directory, sends commands over control connection
- when server receives file transfer command, server opens 2nd TCP data connection (for file) to client
- after transferring one file, server closes data connection

- server opens another TCP data connection to transfer another file
- control connection: "out of band"
- FTP server maintains
 "state": current directory,
 earlier authentication

FTP commands, responses

sample commands:

- sent as ASCII text over control channel
- USER username
- * PASS password
- LIST return list of file in current directory
- RETR filename retrieves (gets) file
- STOR filename stores (puts) file onto remote host

sample return codes

- status code and phrase (as in HTTP)
- * 331 Username OK, password required
- 125 data
 connection
 already open;
 transfer starting
- 425 Can't open
 data connection
- 452 Error writing
 file

Chapter 2: outline

- 2.1 principles of network applications
 - app architectures
 - app requirements
- 2.2 Web and HTTP
- 2.3 FTP
- 2.4 electronic mail
 - SMTP, POP3, IMAP
- 2.5 **DNS**

2-49

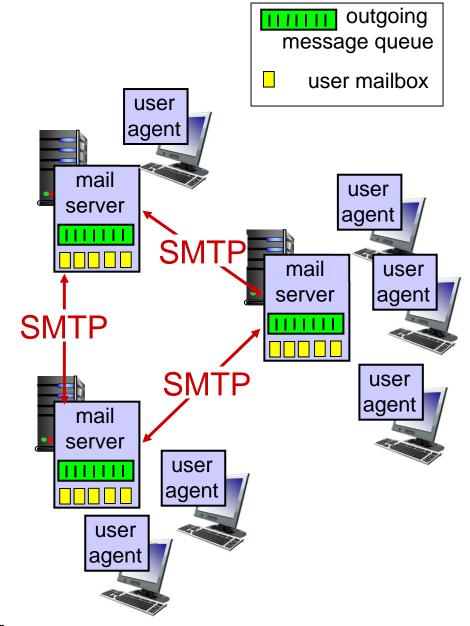

Electronic mail

Three major components:

- user agents
- mail servers
- simple mail transfer protocol: SMTP

User Agent

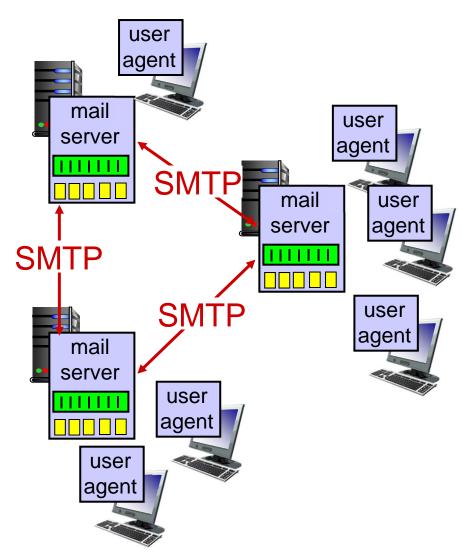

- * a.k.a. "mail reader"
- composing, editing, reading mail messages
- e.g., Outlook, Thunderbird, iPhone mail client
- outgoing, incoming messages stored on server

Electronic mail: mail servers

mail servers:

- mailbox contains incoming messages for user
- message queue of outgoing (to be sent) mail messages
- SMTP protocol between mail servers to send email messages
 - "client" : sending mail server
 - "server": receiving mail server

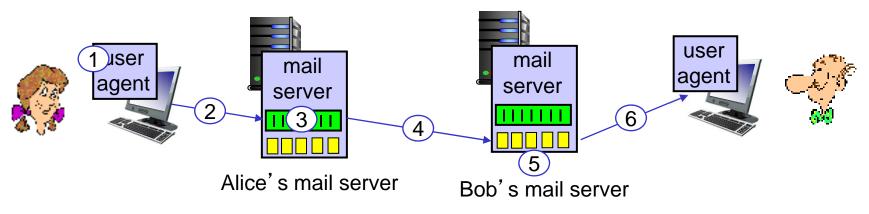

Electronic Mail: SMTP [RFC 2821]

- uses TCP to reliably transfer email message from client to server, port 25
- direct transfer: sending server to receiving server
- three phases of transfer
 - handshaking (greeting)
 - transfer of messages
 - closure
- command/response interaction (like HTTP, FTP)
 - commands: ASCII text
 - response: status code and phrase
- messages must be in 7-bit ASCII

Scenario: Alice sends message to Bob

- I) Alice uses UA to compose message "to" bob@someschool.edu
- 2) Alice's UA sends message to her mail server; message placed in message queue
- 3) client side of SMTP opens TCP connection with Bob's mail server

- 4) SMTP client sends Alice's message over the TCP connection
- 5) Bob's mail server places the message in Bob's mailbox
- 6) Bob invokes his user agent to read message

Sample SMTP interaction

```
S: 220 hamburger.edu
C: HELO crepes.fr
S: 250 Hello crepes.fr, pleased to meet you
C: MAIL FROM: <alice@crepes.fr>
S: 250 alice@crepes.fr... Sender ok
C: RCPT TO: <bob@hamburger.edu>
S: 250 bob@hamburger.edu ... Recipient ok
C: DATA
S: 354 Enter mail, end with "." on a line by itself
C: Do you like ketchup?
C: How about pickles?
C:
S: 250 Message accepted for delivery
C: QUIT
S: 221 hamburger.edu closing connection
```

Try SMTP interaction for yourself:

- * telnet servername 25
- see 220 reply from server
- enter HELO, MAIL FROM, RCPT TO, DATA, QUIT commands

above lets you send email without using email client (reader)

SMTP: final words

- SMTP uses persistent connections
- SMTP requires message (header & body) to be in 7-bit ASCII
- SMTP server uses
 CRLF.CRLF to
 determine end of message

comparison with HTTP:

- HTTP: pull
- SMTP: push
- both have ASCII command/response interaction, status codes
- HTTP: each object encapsulated in its own response msg
- SMTP: multiple objects sent in multipart msg

Mail message format

SMTP: protocol for exchanging email msgs

RFC 822: standard for text message format:

• header lines, e.g.,

• To:

• From:

• Subject:

different from SMTP MAIL

FROM, RCPT TO:

commands!

ASCII characters only

Body: the "message"

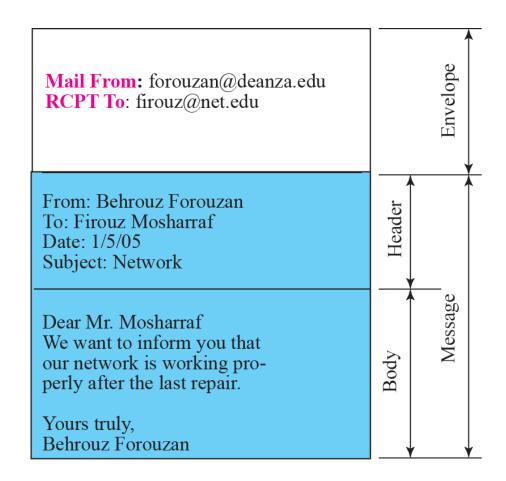

Firouz Mosharraf Com-Net Cupertino, CA 95014

Firouz Mosharraf Com-Net Cupertino, CA 95014 Jan. 5, 2005

Subject: Network

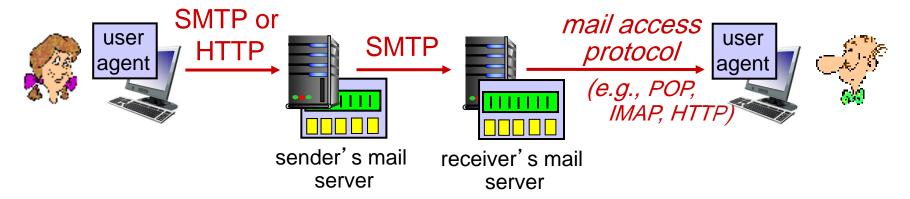

Dear Mr. Mosharraf We want to inform you that our network is working properly after the last repair.

Yours truly, Behrouz Forouzan

TCP/IP Protocol Suite chapter 23, 20th slide

Mail access protocols

- * SMTP: delivery/storage to receiver's server
- mail access protocol: retrieval from server
 - POP: Post Office Protocol [RFC 1939]: authorization, download
 - IMAP: Internet Mail Access Protocol [RFC 1730]: more features, including manipulation of stored msgs on server
 - HTTP: gmail, Hotmail, Yahoo! Mail, etc.

POP3 protocol

authorization phase

- client commands:
 - user: declare username
 - pass: password
- server responses
 - +OK
 - -ERR

transaction phase, client:

- list: list message numbers
- retr: retrieve message by number
- dele: delete
- quit

```
S: +OK POP3 server ready
C: user bob
S: +OK
C: pass hungry
S: +OK user successfully logged on
C: list
s: 1 498
S: 2 912
C: retr 1
S: <message 1 contents>
C: dele 1
C: retr 2
S: <message 2 contents>
S:
C: dele 2
C: quit
S: +OK POP3 server signing off
```

POP3 (more) and IMAP

more about POP3

- previous example uses POP3 "download and delete" mode
 - Bob cannot re-read email if he changes client
- POP3 "download-andkeep": copies of messages on different clients
- POP3 is stateless across sessions

IMAP

- keeps all messages in one place: at server
- allows user to organize messages in folders
- keeps user state across sessions:
 - names of folders and mappings between message IDs and folder name

2-61

Chapter 2: outline

- 2.1 principles of network applications
 - app architectures
 - app requirements
- 2.2 Web and HTTP
- 2.3 FTP
- 2.4 electronic mail
 - SMTP, POP3, IMAP
- 2.5 DNS

DNS: domain name system

people: many identifiers:

SSN, name, passport #

Internet hosts, routers:

- IP address (32 bit) used for addressing datagrams
- "name", e.g., www.yahoo.com used by humans
- Q: how to map between IP address and name, and vice versa?

Domain Name System:

- distributed database implemented in hierarchy of many name servers
- application-layer protocol: hosts, name servers communicate to resolve names (address/name translation)
 - note: core Internet function, implemented as applicationlayer protocol
 - complexity at network's "edge"

DNS: services, structure

DNS services

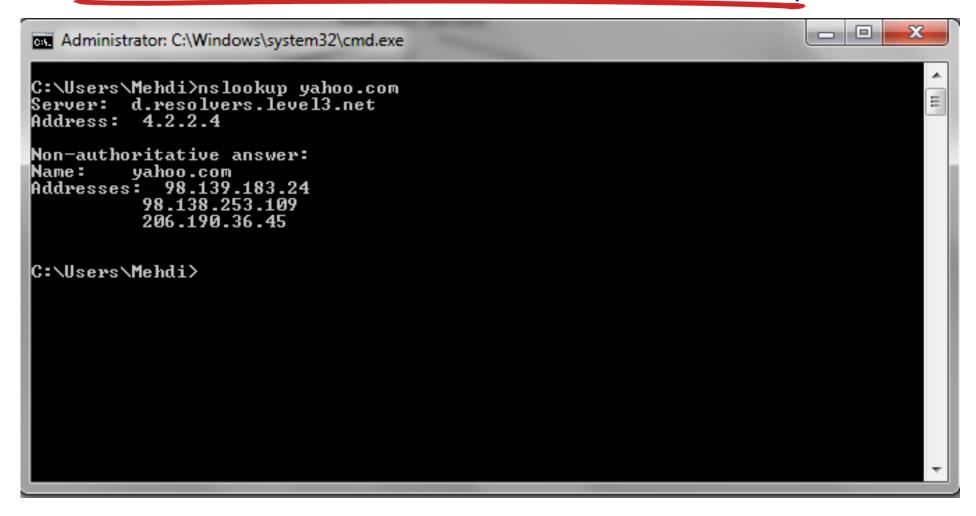

- hostname to IP address translation
- host aliasing
 - canonical, alias names
- mail server aliasing
- load distribution
 - replicated Web servers: many IP addresses correspond to one name

why not centralize DNS?

- single point of failure
- traffic volume
- distant centralized database
- maintenance

A: doesn't scale!

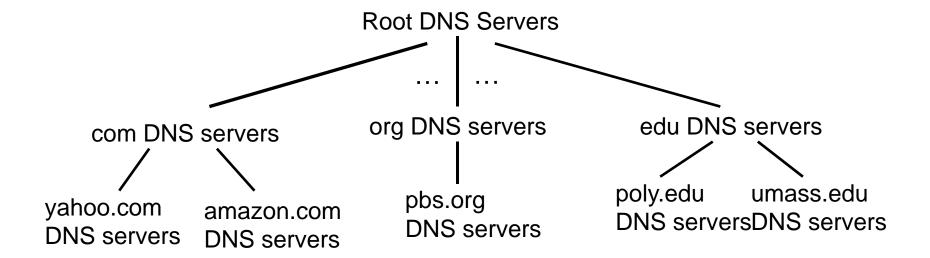

DNS: services (Load Distribution)

DNS: services (Load Distribution)

```
Administrator: C:\Windows\system32\cmd.exe
C:\Users\Mehdi>nslookup yahoo.com
Server: d.resolvers.level3.net
Address: 4.2.2.4
Non-authoritative answer:
DNS request timed out.
    timeout was 2 seconds.
Name:
         yahoo.com
Addresses: 206.190.36.45
          98.138.253.109
          98.139.183.24
C:\Users\Mehdi>_
```

DNS: a distributed, hierarchical database

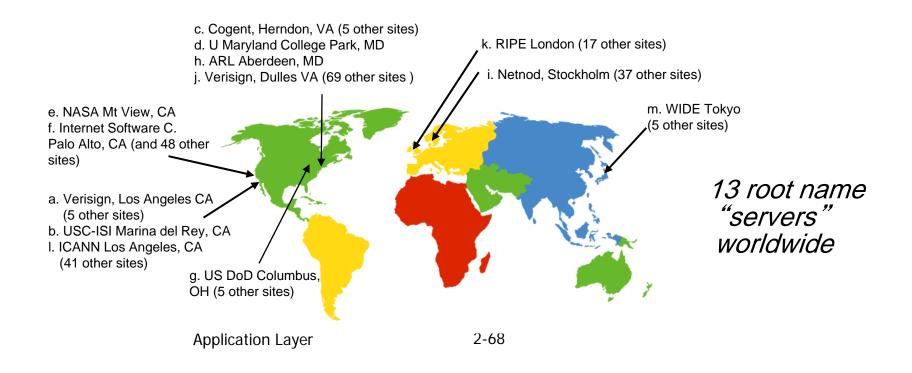

client wants IP for www.amazon.com; Ist approx:

- client queries root server to find com DNS server
- client queries .com DNS server to get amazon.com DNS server
- client queries amazon.com DNS server to get IP address for www.amazon.com

DNS: root name servers

- contacted by local name server that can not resolve name
- root name server:
 - contacts authoritative name server if name mapping not known
 - gets mapping
 - returns mapping to local name server

TLD, authoritative servers

top-level domain (TLD) servers:

- responsible for com, org, net, edu, aero, jobs, museums, and all top-level country domains, e.g.: uk, fr, ca, jp and ir.
- Network Solutions maintains servers for .com TLD
- Educause for .edu TLD

authoritative DNS servers:

- organization's own DNS server(s), providing authoritative hostname to IP mappings for organization's named hosts
- can be maintained by organization or service provider

Local DNS name server

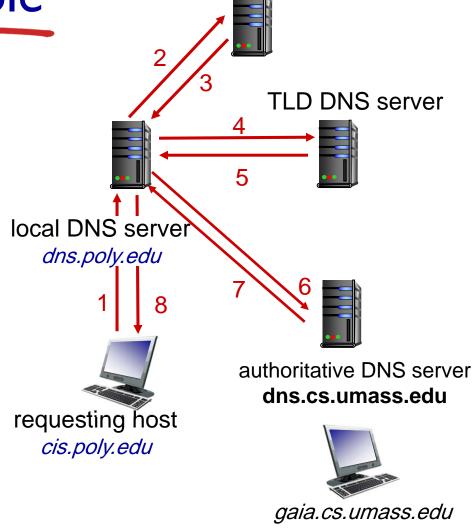

- does not strictly belong to hierarchy
- each ISP (residential ISP, company, university) has one
 - also called "default name server"
- when host makes DNS query, query is sent to its local DNS server
 - has local cache of recent name-to-address translation pairs (but may be out of date!)
 - acts as proxy, forwards query into hierarchy

DNS name resolution example

 host at cis.poly.edu wants IP address for gaia.cs.umass.edu

iterated query:

- contacted server replies with name of server to contact
- "I don't know this name, but ask this server"

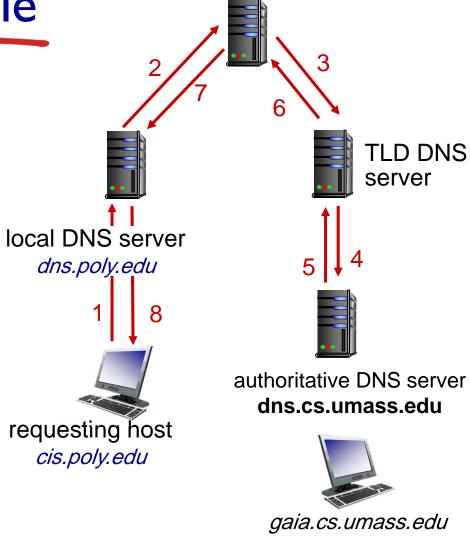

root DNS server

DNS name resolution example

recursive query:

- puts burden of name resolution on contacted name server
- heavy load at upper levels of hierarchy?

root DNS server

DNS: caching, updating records

- once (any) name server learns mapping, it caches mapping
 - cache entries timeout (disappear) after some time (TTL)
 - TLD servers typically cached in local name servers
 - thus root name servers not often visited
- cached entries may be out-of-date (best effort name-to-address translation!)
 - if name host changes IP address, may not be known Internet-wide until all TTLs expire
- update/notify mechanisms proposed IETF standard
 - RFC 2136

DNS records

DNS: distributed db storing resource records (RR)

RR format: (name, value, type, ttl)

type=A

- name is hostname
- value is IP address

type=NS

- name is domain (e.g., foo.com)
- value is hostname of authoritative name server for this domain

type=CNAME

- name is alias name for some "canonical" (the real) name
- www.ibm.com is really servereast.backup2.ibm.com
- value is canonical name

type=MX

 value is name of mailserver associated with name

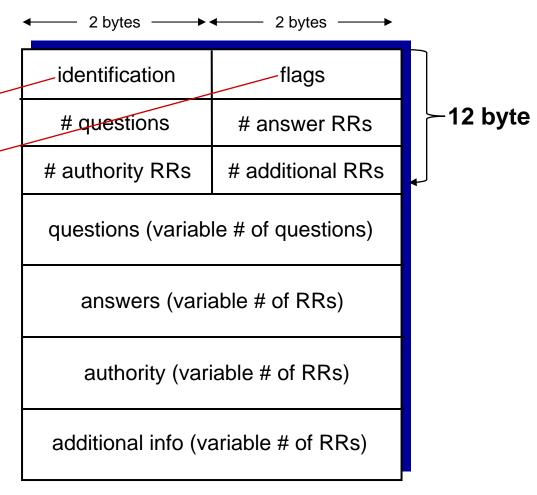

DNS protocol, messages

query and reply messages, both with same message

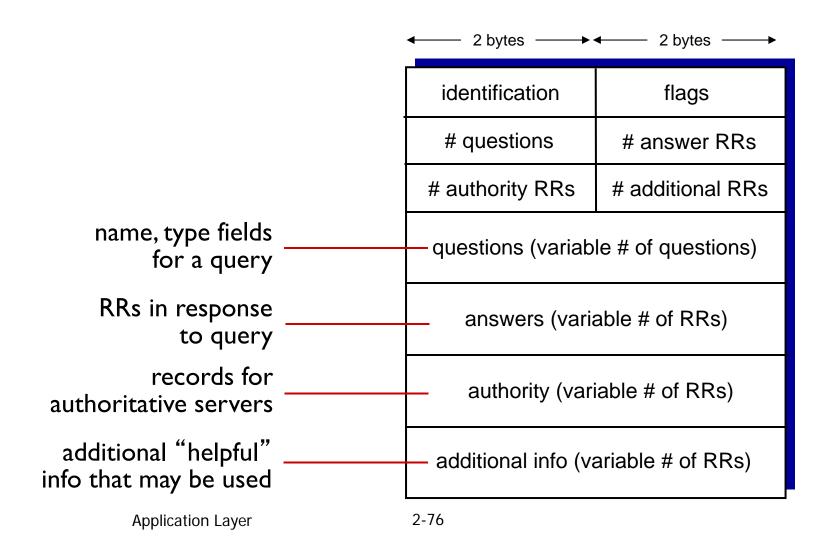

format

msg header

- identification: 16 bit # for query, reply to query uses same #
- flags:
 - query or reply
 - recursion desired
 - recursion available
 - reply is authoritative

DNS protocol, messages

Inserting records into DNS

- example: new startup "Network Utopia"
- register name networkuptopia.com at DNS registrar (e.g., Network Solutions)
 - provide names, IP addresses of authoritative name server (primary and secondary)
 - registrar inserts two RRs into .com TLD server: (networkutopia.com, dnsl.networkutopia.com, NS) (dnsl.networkutopia.com, 212.212.212.1, A)
- create authoritative server type A record for www.networkuptopia.com; type MX record for networkutopia.com

Chapter 2: summary

our study of network apps now complete!

- application architectures
 - client-server
 - P2P
- application service requirements:
 - reliability, bandwidth, delay
- Internet transport service model
 - connection-oriented, reliable: TCP
 - unreliable, datagrams: UDP

- specific protocols:
 - HTTP
 - FTP
 - SMTP, POP, IMAP
 - DNS

Chapter 2: summary

most importantly: learned about protocols!

- typical request/reply message exchange:
 - client requests info or service
 - server responds with data, status code
- message formats:
 - headers: fields giving info about data
 - data: info being communicated

important themes:

- control vs. data msgs
 - in-band, out-of-band
- centralized vs. decentralized
- stateless vs. stateful
- reliable vs. unreliable msg transfer
- "complexity at network edge"
